Whereas the donor's serum agglutinated the recipient's cells only to 32 (see Test I), yet random A sera agglutinated these cells on an average of 128 to 256, the range being 8 to 1024 (see Test IV). Elsdon-Dew (1936) found the anti-B titre of six A sera to be respectively 512, 16, 64, 32, 128, and 64. Aubert, Boorman, Dodd, and Loutit (1942) found that 22.4% of O sera had anti-B titres of 64, and 13.6% a titre of 256; if the dilution factor caused by adding the volume of red-cells in the titrations be included, the figures become 128 and 512. Clearly the donor's anti-B titre was comparatively low. Aubert, Boorman, Dodd, and Loutit (1942) transfused conscious group A recipients with O sera of high anti-A titre and did not produce dangerous or fatal reactions. Very high titre sera did, however, cause some destruction of erythrocytes. It seems reasonable to assume that the low titre anti-B iso-agglutinin of the donor in no way harmed the recipient's cells, and absence of

symptoms may in part be attributed to this. For instance, the haemoglobin did not fall, being 60% before and 66% the sixth day after incompatible transfusion. The recipient's anti-A iso-agglutinin was but little weaker than the average (compare Tests II and III). Elsdon-Dew (1936) found the anti-A titre of five B sera to be respectively 2048, 32, 256, 2048, and 64. Aubert, Boorman, Dodd, and Loutit (1942) found 26% of O sera had anti-A titres of 256, and 40% had titres of 512 or higher, though, as noted above, these figures do not include the dilution factor. The red cells of donor and recipient were of average sensitivity (see Tests III and IV). In contrast to the findings of Burnham and of Grove and Crum, absence of symptoms was not attributable to inability of the iso-agglutinins to function at 37° C.

As pointed out by Aubert, Boorman, and Dodd (1942), plasma or serum agglutinin may function as an *in vitro* neutralizer of iso-agglutinins in transfused blood, plasma, or serum. However, Aubert, Boorman, Dodd, and Loutit (1942) observed that even if the recipient's plasma has considerable agglutinin content, this will not completely protect the recipient's cells from transfused incompatible iso-agglutinins. To assess agglutinin content of plasma and sera, and therefore their inhibiting power, Aubert, Boorman, and Dodd (1942) devised the "inhibition index" test. Briefly, A or B sera were titrated in saline and the end-point noted. The sera were then mixed in equal proportions and again titrated. Certain sera reduced or inhibited the titre of other sera—an observation also made by Elsdon-Dew (1936). Thus if a titre was reduced from 128 to 16 the inhibition index of the inhibiting serum was expressed as 8. It was indicated that the test was only an approximate guide to the amount of inhibiting substance present. The presence of group-specific substances A and B in solution partly explains reduced titres of pooled plasma or serum.

Seven months after the incompatible transfusion, when the anti-A titre had approximated the pre-transfusion level, the inhibition indices of the recipient's and donor's sera were investigated. It was 0 for each. The titration technique was that already described. The pooled sera were incubated for one hour at 37° C. In titrating the pooled sera the dilution caused by mixing the sera was taken into account and the titre of the first tube was reckoned as 4 instead of 2. There was thus no *in vitro* evidence that the recipient's plasma protected its erythrocytes from the donor's iso-agglutinins, and vice versa. Presumably the donor's iso-agglutinins were absorbed by the tissues of the recipient. Aubert, Boorman, and Dodd (1942) found no evidence that the agglutinating substance in transfused serum neutralized the recipient's iso-agglutinins.

### Conclusion

*In vitro* tests did not fully explain absence of symptoms, though the donor's cells were eliminated in five days. Absence of symptoms may be due to the fact that the incompatible blood was injected at a very slow drip rate. Mollison (1943) mentioned that reactions to incompatible transfusion seemed to be less severe than formerly, and that this might be due to the fact that transfusions are now commonly given at a drip rate. The danger of transfusing compatible blood rapidly into chronically anaemic recipients has been previously referred to by me (Drummond, 1943) and by others. If the blood is incompatible the effects are almost certain to be aggravated. It is possible that the favourable outcome in the case here reported is attributable to the very slow rate of injection of the incompatible blood.

My thanks are due to the medical staff of the hospital concerned for permission to investigate this case, and to Prof. J. B. Duguid and Dr. J. Gough of the Department of Pathology, Welsh National School of Medicine, for helpful criticism.

**ANXIETY; ALOPECIA AREATA; NEUROFIBROMATOSIS: AURICULAR FIBRILLATION****DESCRIPTION OF A PATIENT**

BY

**DOUGLAS HUBBLE, M.D.***Assistant Physician, Derbyshire Royal Infirmary; Physician, Derbyshire Hospital for Sick Children*

AND

**C. H. ROGERSON, M.D., M.R.C.P., D.P.M.***Medical Director, Cassel Hospital for Functional Nervous Disorders*

The following account of a patient is published because he displayed three disorders whose aetiology and pathogenesis are unknown. His fourth disorder—a psychological state dependent on an unusual personality—appeared to us to stand in aetiological relationship to two of his three abnormal physical states.

**Case Record**

The patient, a house-painter aged 39, was referred to the Derbyshire Royal Infirmary on May 5, 1943, by Dr. Eileen Crowley for treatment of auricular fibrillation.

**Personal History**

His childhood was quite normal, healthy, and happy. He does not recall any fears or anxieties as a boy. He was the leader of a small group of boys who were rather "young devils." At the age of 12 he passed the necessary examination to enable him to leave school, and he went to work as a riveter's mate. By the time he was 14 he had held a variety of jobs and was earning £2 15s. a week (1918). He was restless and ambitious, and had come to realize how many limitations there were in the life of his childhood; he saw no reason why he should not go a long way. He began to serve an apprenticeship in the carriage-and-wagon works (Midland Railway), but could not tolerate the attempts of the older men to put him in his place. He had a row with one of them and walked out, thinking that he could easily get another job. The post-war difficulties had then begun and he was unable to get work. His pride was hurt, so he falsified his age and joined the Grenadier Guards at 15 years. His father got him out again, but only by paying a forfeit. He was still unable to get a job, and was burning with resentment. He rejoined the Army to get back the forfeit, and then malingered until he was discharged by the Medical Board. He felt better after this, and came back home seeking work.

Then began a long and difficult period of partial employment. In 1922, aged 18, he married a girl two years older than himself whom he had got pregnant. She already had one illegitimate child. He had to live on 34s. a week, so they had a room in the house of her brother-in-law. Soon he found that she had had the illegitimate child by this man, and he became furiously jealous. He thought and dreamed of nothing else for weeks, and made scenes by following the brother-in-law about the streets. His pride was desperately hurt, and it was some years before he ceased to worry about his wife's conduct. At this time (in 1926), aged 22, he developed two patches of alopecia areata on his head.

He made fresh efforts to overcome his difficulties, working partly as a painter and partly as a pianist (he had taught himself to play the piano). Financial worries, however, continued to press on him, and on one occasion he was in prison for failure to pay a debt. Gradually his health deteriorated, his finances grew worse, and his alopecia recurred. Shortly afterwards he got a job at a hospital as a painter, and so had regular work for the first time for years (1932—aged 28). His worries were apparently over, for he had every chance of getting out of his financial difficulties.

Presently he found that a new skin affliction was developing in the shape of nodules beneath the skin of the back of his neck. He became preoccupied with his condition, and after seeing a propaganda film thought he had syphilis. He went to several doctors and had repeated Wassermann tests before he was satisfied about this, and, even so, the doubts have recurred at intervals since then. His hair continued to fall out. He became very ashamed of his appearance; he would try to dodge people, and thought that they were looking curiously at him. This only served to increase his determination to make good and to show his real worth.

After about seven years' work at the hospital he started a house-painting business, and with characteristic energy was soon doing well (1939). When the air raids began he found that there was not much work for him to do, so he joined the A.R.P. He realized that he would get extra money if he could drive a lorry; so he bought a car, learned to drive it in one or two evenings, and passed the necessary test. When the raids died down he was able to go back to his painting business, which continued to do well. He put a

great deal of effort into every job he undertook, worrying greatly over the details of it. In April, 1942, one of his men stole a large sum of money from a firm for which he was doing a job. The man turned out to be a thief who had stolen from other clients of his and the police had to make investigations all round the district where he worked. He was exceedingly distressed, and feared that no one would employ him any more. His heart began to beat irregularly and was shortly afterwards found by his doctor to be fibrillating.

**Family History**

The patient is either the sixth or the seventh of a family of twelve or thirteen children (doubtful about one older child who died). His mother was a fine woman who came from a healthy and highly respected family, and married rather beneath her. She was a great worker in good causes, was full of energy, and used to organize parades on behalf of the hospitals. She died of cardiac disease at 68 years. His father—a blacksmith—was a staunch teetotaler, and a good man. He suffered from rheumatism, and died of an unknown disorder when 65. The patient's paternal grandfather was blind during the latter part of his life and was extremely poor. Of the patient's brothers and sisters eight are still living. All have done very well. Three brothers are at present sergeants in the Middle East. He had no knowledge of any familial illness; nor does he know of any abnormalities of the skin or hair occurring in his parents or siblings.

His wife, aged 40, is in good health, but is a nervous woman. Of their three children, one daughter, aged 21, has a few small pigmented moles, but not café-au-lait patches or skin tumours. She bites her nails and has many night terrors. Otherwise her health is good. The other daughter, aged 18, has one small café-au-lait patch on the neck and many small pigmented moles, but no freckling or skin tumours. She has good health and a stable personality. The son, aged 14, has about 30 café-au-lait patches, the largest 5 in by 4 in. on the back of the left thigh, diffuse freckling on the trunk, but no skin tumours. He has good health, and an impulsive, aggressive temperament, but his intelligence is poor. Under-development of sexual organs and a high palatal arch (speech defect) are other things of note.

**Medical History and Habits**

The patient's hair has been much in the condition described below for eleven years; it has grown slightly during the last two months. He now has to shave once a week, but for the preceding ten years had not shaved at all. The large tumour over the crest of the left

FIG. 1.—Back view of patient.

iliacum has been present as long as he can remember, but he does not think it was there in infancy. The other skin tumours appeared in 1933 and increased steadily in size and numbers until 1939; few if any new ones have developed in the last four years. Although he was aware of his cardiac irregularity at its onset in June, 1942, yet he is now for the most part unconscious of it.

His habit for tobacco is 40 to 50 cigarettes a day and for alcohol 2 to 3 pints of beer a day. He has had no loss of libido at any

time. He is capable of great physical activity, and has had no other illness of importance in his life; no rheumatic fever or rheumatism. He well illustrated his impulsiveness by discharging himself from the hospital on the morrow of his admission and telephoning the following evening asking for readmission.

Examination showed him to be a healthy active man: height 5 ft. 10½ in., weight 11 st. 12 lb. Hair: Fine, sparse hair on scalp; no eyebrows; eyelashes very thin and poor; axillary hair very thin; no visible chest hair; pubic hair very thin and short. Skin: Diffuse freckling on the trunk and a few small café-au-lait patches on the abdomen and lower limbs. Nails are picked and bitten very short. There are no lesions on the mucous membranes. There is no detectable thickening of any nerves, nor are there any fibromata along their course.

**Neurofibromata.**—Hundreds of small skin tumours, varying in size from 1 mm. to 2 cm., are present on the face, scalp, neck, trunk, and limbs (Fig. 1). There is a larger one—a soft sessile tumour measuring 12 cm. across—just above the crest of the left ilium. These tumours occur with the greatest frequency on the scalp, face, neck, and trunk, but they are present in progressively diminishing numbers towards the periphery of the upper and lower limbs. The hands are practically free, and the feet have only one or two small nodules on the dorsum. Some of the tumours are under the skin, but the majority are on the surface of the skin as sessile tumours. They correspond well with the usual textbook descriptions of neurofibromata, which feel as if they were "herniated" through the fascia and can be "reduced" by pressure. The tumours are not painful.

**Circulatory System.**—The pulse is grossly irregular in force and frequency. The cardiac rate is 104 and the pulse rate 86; blood pressure 110/75. The retinal vessels are normal and there is no evidence of arteriosclerosis anywhere. There are no murmurs in the cardiac area, and the sounds are normal. The diagnosis of auricular fibrillation is confirmed by electrocardiogram (see Figs. 2 and 3), and radiographs show a heart shadow normal in size and shape.

The thyroid gland is not enlarged and there is no evidence of thyrotoxicosis: no tremor and no exophthalmos. There is no evidence of other endocrine disorder. Examination of the central nervous system revealed no abnormality, but he has very brisk muscle reflexes. The hands and feet are damp. The urine is normal. The blood sedimentation rate is 10 mm. in the first hour and 18 mm. in the second. His blood count shows: Hb, 103%; red cells, 5,480,000; white cells, 12,000, of which 2,440 are lymphocytes and 610 monocytes; the remaining 75% are neutrophils. His blood cholesterol is 115 mg. per 100 c.cm. of blood. His Wassermann reaction and

FIG. 2.—Electrocardiogram before quinidine therapy.

FIG. 3.—Electrocardiogram after 25 gr. of quinidine daily.

flocculation test are negative. A fractional test meal showed a histamine-fast achlorhydria in all specimens.

The report (Dr. G. R. Osborn) on the microscopical structure of a removed tumour from the back of the neck is: "The cutaneous nodule excised measures about 8 mm. in diameter. Microscopically this is a neurofibroma (fibroma molluscum). The most prominent nervous element is whorled groups of Schwann cells (schwannoma). Around these there is fibrous tissue with many small blood vessels. Nothing suggestive of malignancy seen. **Diagnosis:** neurofibroma."

### Psychiatric Summary

Coming from a superior working-class background, possessed of great drive and ambition, impulsive and resentful of failure, this patient suffered great frustration and anxiety, at the peak of which he twice developed alopecia areata. The second attack of alopecia progressed in spite of the partial relief of anxiety, and at this time he developed the multiple subcutaneous nodules. A third severe period of anxiety ten years later coincided with the development of auricular fibrillation. He is a well-spoken and obviously intelligent man who has educated himself beyond the level he would have attained when he left school at 12. His whole attitude indicates the possession of quite exceptional drive and ambition, with a keen sense of pride in his own achievements and strong resentment against the social and economic difficulties which have held him back and the disease which has disfigured him. His impulsiveness is well shown by his history. He is inclined to brood over his difficulties; his anxiety and desire for success reach an obsessional pitch at times. Some of his worries have definitely shown an obsessional character.

### Diagnosis: Progress

The case was diagnosed as one of anxiety, alopecia areata, neurofibromatosis, and auricular fibrillation.

Quinidine therapy was started soon after admission, and when the dose had reached 25 gr. a day the patient's cardiac rhythm switched to normal (Figs. 2 and 3). He was discharged on July 9, 1943, on a maintenance dose of 5 gr. of quinidine twice daily, which has been continued till now except for one month when, unknown to him, aspirin was substituted for his quinidine. He had no further fibrillation until Dec., 1943, when his cardiac rhythm became irregular again, after an attack of influenza. His heart was quickly converted to a normal rhythm with 20 gr. of quinidine in the day.

### Comment

Von Recklinghausen's disease is characterized by neurofibromata and by abnormal pigmentation, as described in this man. These café-au-lait patches and diffuse frecklings are regarded as *formes frustes* of the disease (Parkes Weber, 1909) when they appear in the relations of those suffering from its fully developed forms. The disease is now thought to be inherited as a Mendelian dominant. More interesting than the disease itself are the abnormalities which are often associated with it. These are of great variety, and include mental, endocrine, autonomic, and skeletal disorders: they have been reviewed in a paper by Levin and Behrman (1940). Although defective development of pubic hair is mentioned in that review, there is no report, either in this or in other papers, of an associated alopecia areata. Auricular fibrillation has once before been described (Clarke and Wakefield, 1926) in association with neurofibromatosis, and these authors attribute it to an involvement of the vagus nerve by the tumours. No necropsy was obtained on their patient, but, according to them, the vagus nerve is the commonest of the cranial nerves to be involved by neurofibromata. It is difficult to believe that the auricular fibrillation in our patient could have been due to implication of any part of the autonomic system by the tumours, since quinidine has returned his heart's rhythm to normal, and the rhythm has remained regular even when the quinidine has been stopped. It is simpler to postulate that the auricular fibrillation and the alopecia areata are related to the neurofibromatosis in the same way as are the vast array of associated disorders already described in the literature—and that is, at a genetic level.

Levin and Behrman quote the views of Pende (supported by "many learned arguments"), who in 1910 suggested that neurofibromatosis has a place in a large group of endocrine-sympathetic dystrophies, among which he also included scleroderma and painful lipomatosis. For the production of these conditions two factors are required:

- (1) A *constitutional factor*, represented by an abnormality of the endocrine-sympathetic system, which may be hereditary, intra-uterine, or extra-uterine during the period of growth; and
- (2) A *precipitating factor*, such as shock, trauma, toxins, or infection, which through its effects on the endocrine-sympathetic system acts as a stimulus to embryonal elements of the autonomic system in the skin.

This appears to us as satisfactory an explanation of the aetiology of neurofibromatosis as can at present be attempted, and it can be similarly applied to alopecia areata and to idiopathic auricular fibrillation. Alopecia areata has been related to emotional disturbances by numerous observers. This association has been denied with equal frequency. In our

experience of alopecia areata it has not been difficult, in both children and adults, to demonstrate a preceding emotional stress. Auricular fibrillation is associated with mitral stenosis, with thyrotoxicosis, and with myocardial degeneration. None of these conditions was present in our patient. Distinct from these varieties is another group called "paroxysmal auricular fibrillation." It is characteristic of these paroxysms that they last only a few hours or days, that they recur frequently, and that they are corrected to a normal rhythm with ease and safety by quinidine therapy. It is difficult to define as paroxysmal a condition which has persisted for eighteen months, as in our patient. When auricular fibrillation is unassociated with any organic disease and when it is preceded by adequate emotional tension, as in this man, it is reasonable to name it a cardiac neurosis.

This man's illness illustrates the varied factors—genetic, constitutional, psychological, environmental, and mechanistic—which we seek to assess in an evaluation of disease in man, but it also indicates how remote is the day of full comprehension. The link between the emotion which fails to find its appropriate physical discharge and the consequent physical disorder is usually assumed to be the vegetative nervous system; while this path is probable, the endocrine system offers an alternative mechanism. Both alopecia and auricular fibrillation are sometimes associated with endocrine disorder. We are far from a coherent conception of the mechanism by which emotional stress is translated into physical disorder. Not to seek this link, however, or, worse, to ignore its existence, is a heretical denial of the integrity of mind and body.

The present controversy between those who support the "biological" approach to aetiology ("What sort of man is this, and why did he become ill in the way he did?") and those who are preoccupied with mechanism ("What has the patient got?") implies a schism in diagnosis and therapy which is quite unreal. In our patient it was possible to define closely but one of the faulty mechanisms involved (i.e., auricular fibrillation), and here it was easy to intervene to the man's great advantage. While the biological approach to aetiology had in this case none of this immediate practical quality, yet it contributed to a fuller understanding of the sufferer and his disorder. The physician cannot disdain any approach which increases either his understanding or his capacity to help his patient.

We are grateful to Dr. J. T. Ingram, dermatologist to the General Infirmary at Leeds, for his expert help and criticism in the preparation of this paper, and to Dr. G. R. Osborn, pathologist to the Derbyshire Royal Infirmary, for the photograph and the report on the sections of the tumour.

## A MILK-BORNE OUTBREAK OF GASTRO-ENTERITIS DUE TO SALMONELLA DUBLIN

BY

P. L. SUTHERLAND, D.Sc., M.B., Ch.B.

Pathologist and Bacteriologist, West Riding County Council

AND

F. M. BERGER, M.D.

Assistant Bacteriologist, West Riding County Council

On Aug. 19, 1943, the County Medical Officer of the West Riding of Yorkshire was informed that the practitioners in Knaresborough Urban District had throughout that day been called in to attend to numerous cases of sickness and diarrhoea. Inquiry by the local medical officer of health showed that all the cases had occurred in households supplied with milk from Farm G, situated at a village about two miles distant in an adjoining rural district. Simultaneously cases had occurred among residents at the farm. It therefore seemed that the disease was conveyed by the milk distributed from Farm G. Subsequent investigation proved that the outbreak was caused by *Salmonella dublin*, that the vehicle of infection was milk from Farm G, and that the source of infection was an apparently healthy cow which was a carrier of the organism.

## Symptoms

The onset of the disease was sudden, with sickness or actual vomiting, diarrhoea, headache, and fever ranging from 100° to 102° F. The diarrhoea was profuse, but there was no blood or mucus in the motions. The febrile period lasted for about three days at the longest. A profuse herpetic eruption on the lips and nose was noted in a small proportion of cases. One patient complained of persistent headache for some days during convalescence. Many cases were very mild, and some patients were not confined to bed or were confined to bed only for a day. There were no deaths.

On Aug. 29 a baby 2 months old died of meningitis, but unfortunately no bacteriological or post-mortem examination was made. This child, which was breast-fed, did not suffer from diarrhoea. It was a member of a household of five persons supplied with milk from Farm G. One member of the household (not the mother) had been ill with diarrhoea about Aug. 19. This case is noted because Smith (1934) has described two sporadic cases of meningitis in children due to *S. dublin*.

## Incubation Period

Cases occurred among the residents at a hostel for evacuee children, from particulars of which the duration of the incubation period was determined. The circumstances also confirmed the fact that the outbreak was milk-borne. At the hostel there were 7 children and a staff consisting of a matron, a nurse, and a cook. A daily charwoman was also employed. At the time of the outbreak a friend of the nurse was staying there. The hostel was supplied with milk from Farm G, and the residents, with the exception of the matron and cook, had milk at about 11 a.m. on Aug. 18. The charwoman also had milk on that day. About 2 a.m. on the 19th three of the children complained of sickness and diarrhoea, and by 8 a.m. all the children, the nurse, and her friend were ill. The charwoman, on arriving at the hostel that morning, complained that she had suffered from sickness and diarrhoea during the night. The matron and cook, who did not take milk, remained well.

The interval of time between the consumption of milk and the onset of symptoms varied from 14 to 20 hours. This relatively long incubation period suggested infection with living *Salmonella* organisms.

## Outbreak in the Urban District

As the practitioners were requested to notify cases of sickness and diarrhoea it was possible to estimate approximately the magnitude of the outbreak. The total number of cases notified was 162, and 79 households were involved. Some of the known cases were very mild, and it is therefore probable that there were many more cases, which did not come to light as a doctor was not called in. The date of onset of the illness was stated to be Aug. 18 in 2 cases, Aug. 19 in 143 cases, and Aug. 20 in 15 cases; in 2 cases the date was not given. The age and sex incidence is shown in Table 1.

TABLE 1.—Age and Sex Incidence of Cases of Gastro-enteritis notified in the Knaresborough Urban District

Age	Cases	Females	Males
Under 5	35	21	14
5-9	23	12	11

15-24	24	19	5
25-34	23	21	2
35-44	15	10	5
45 and over	26	17	9
Totals	162	104	58

## Outbreak at Farm G

On making investigations at the farm it was found that six persons were resident there: the farmer H. F., aged 70; his son-in-law T. P., aged 36; his three daughters, R. P., aged 36, J. B., aged 32, and W. F., aged 23; and his granddaughter, J. P., aged 9. Two farm labourers—H. R., aged 40, and C. K., aged 35—were employed, but lived with their families in the village and were supplied with milk from the farm. The farmer, his son-in-law, and his granddaughter were ill with sickness and diarrhoea. The other residents and the two labourers were well, and remained well. All the members of

the labourers' families, seven in number, were ill. Other cases were known to have occurred in the village among persons supplied with milk from the farm. Particulars of the cases connected with the farm are given in Table II.

TABLE II.—Particulars of Patients Resident at or Associated with the Farm

Nos. 1 to 6 were resident at the farm; Nos. 7 to 15 were resident in the village.

\* Milker. † Milk distributor.

#### Production and Distribution of the Milk

At the farm there were 20 cows, two of which were dry. The cows were milked by the farmer, his son-in-law, and the labourer H. R. When the farmer and his son-in-law became ill the milking was continued by H. R., assisted by the other labourer, C. K. Milking was done by hand. The milk, of which about 36 gallons were produced daily, was distributed by the farmer's daughters R. P. and W. F. to about 600 registered customers in the urban district and 12 in the rural district, the number of households supplied being about 200. There was only one calf on the farm, and neither the calf nor any of the cows showed evidence or gave a history of enteritis. None of the cows had been recently added to the herd. There were no pigs at the farm and there had been no disease among the poultry.

#### Procedures taken to Prevent the Spread of Infection

When the farm was visited on the morning of Aug. 20 the evidence strongly pointed to the milk as the vehicle of infection, and the first problem which arose and required immediate decision was what steps should be taken with regard to the milk to preclude the possibility of the occurrence of further cases. At that time there was no bacteriological proof that the milk was infected. The results of bacteriological examinations, which had been started very late on the previous evening, had proceeded only far enough to indicate that a pathogenic organism was present in the faeces of some of the cases.

Two courses were open—namely, to prohibit the use of the milk for human consumption or to allow it to be used only after pasteurization and to be distributed only by persons unconnected with the farm. The former procedure would, if adopted, have involved the waste of a considerable amount of milk, which is a valuable and at the present time not too abundant food, besides causing financial loss to the farmer. In view of these considerations it was decided to allow the milk to be used after pasteurization.

On the afternoon of the same day arrangements were made with the local officer of the Ministry of Food and with the Milk-Marketing Board to collect the milk at the farm, take it direct to a pasteurizing plant, and distribute it from there after pasteurization. By this arrangement the milk did not return to the farm. A supply was provided for the farmer's customers, and this was distributed by another retailer. The last delivery of milk direct from the farm was on the morning of Aug. 20. It was also arranged to examine the milk produced at the farm and specimens of faeces and urine of all persons resident at or connected with the farm. Those who had the disease were prohibited from taking part in the milking until declared free from infection, and the milkers were warned to exercise care in the cleansing of their hands and the dairy utensils.

A request was made to the Ministry of Agriculture to have the herd examined by one of its officers. An examination was

made on Aug. 23, and the veterinary officer reported that "several of the cows were found to be affected with cowpox, in some cases very severely, and the teats in these cases were a mass of sores, some of them being wet and runny." The farmer was advised as to treatment of the condition, and was requested to call in his own veterinary surgeon to continue the treatment; to this he agreed. When it was subsequently found that a cow was excreting the organism in the dung, this animal was excluded from the herd and instructions were given not to allow its milk to be mixed with that taken to the pasteurizing plant or to be used for human consumption or fed to animals unless it had previously been boiled.

#### Bacteriological Examination

On Aug. 19 specimens of faeces from 8 patients in the urban district and a specimen of milk collected at the hostel were received for examination. Of these, 7 specimens of faeces and the specimen of milk were found to contain an organism of the *Salmonella* group. The milk was very heavily infected. Two loopfuls spread on a MacConkey plate showed after 24 hours' incubation more non-lactose-fermenting colonies than colonies of coliform organisms. The pathogenic organism was motile and fermented glucose, mannitol, and dulcitol with formation of acid and gas, but gas was at first not abundant. It did not ferment lactose or saccharose; it formed hydrogen sulphide but no indole. It was strongly agglutinated by polyvalent *Salmonella* serum.

The serological identification of the organism proved difficult. It was equally well agglutinated on the slide by typhosum O serum and by *aertrycke* O serum. This was probably due to the presence of an overlapping O antigen XII (Topley and Wilson, 1936). Agglutination to titre carried out in tubes showed a slightly higher titre with typhosum O serum. A weak but definite reaction with *Gaertner* H serum indicated that the organism probably belonged to the enteritidis subgroup. As the organism could not be placed nearer with the sera available, cultures isolated from one of the patients and from the milk were sent to Dr. Joan Taylor, of the *Salmonella* Reference Laboratory, Oxford, who identified them as *Salmonella dublin*.

The examination of the specimen of milk which was collected at the hostel was of interest as it showed not only that the milk was the vehicle of infection but also that it must have been infected on at least two occasions. The specimen was a sample of milk delivered at the hostel on the morning of Aug. 19. At that time all the children, the nurse, and her friend were ill and did not take any of that milk. The milk had not been handled by any of the inmates except the matron and cook, who had not been ill, and therefore it is very unlikely that it could have become infected after delivery at the hostel.

Specimens of faeces and urine from all the residents at the farm and from the two farm labourers and the members of their families were also examined. The organism was shown to be present in the faeces or urine of all the residents at the farm who had been ill, and of five of the seven members of the labourers' families who had been ill. It was found nine times in specimens of faeces and three times in specimens of urine. Cultures made from the material collected from the lesions of the cows suffering from cowpox showed only coagulase-positive golden staphylococci. Repeated examination of samples of bulked milk collected at the farm, of the water supply of the farm, and of water in a stagnant pond on the farm all gave negative results. Repeated examinations of the dung of the calf were also negative.

It is known that infections due to *S. dublin* are especially associated with calves and cattle (Savage, 1940). Conybeare and Thornton (1938) isolated *S. dublin* from the dung of an apparently healthy cow which was shown to have a high serum-agglutinin titre for that organism. In the present outbreak it was impracticable, owing to transport and other difficulties, to collect specimens of dung and blood of all members of the herd. It was possible, however, to obtain samples of milk from individual cows, and these were examined culturally and serologically. The cultures were negative in every case, but evidence of infection was obtained by investigating the agglutinin content of the milk. The individual samples of milk were mixed with rennet and the mixture was allowed

to stand on the bench until the whey had separated. Twofold dilutions of whey were prepared with 0.85% sodium chloride solution in a volume of 0.5 ml., the dilutions ranging from 1 in 2 to 1 in 256. Saline controls and normal milk controls were also set up at the time of the experiment. To all the tubes 0.5 ml. of a suspension of *S. dublin* was added. The opacity of this suspension was adjusted with normal saline solution until it was approximately the same as that of a standard suspension. The suspension was preserved by the addition of 0.4% of chloroform. All the tubes were incubated at 50° C. for two hours and allowed to stand on the bench overnight. The milk of Cow No. 10 was found to contain agglutinins for *S. dublin*, the titre being 1 in 32. The test was repeated with another specimen of milk of Cow No. 10, and a titre of 1 in 64 was obtained. The agglutination was of the flaky H type. The whey obtained from the milk of all the other cows did not agglutinate *S. dublin* in a dilution of 1 in 4. Subsequent examination of the dung of Cow No. 10 showed the presence of *S. dublin*. Two samples of dung were examined: in both an almost pure culture of *S. dublin* was obtained on direct plating on Leifson's medium, and many colonies were also detected on MacConkey medium. The identity of the organism was confirmed by Dr. Joan Taylor.

### Discussion

Three extensive outbreaks of milk-borne gastro-enteritis due to *S. dublin* have been reported in this country. In the first two outbreaks, which occurred in Dundee in 1926 and 1927 and were reported by Tulloch (1939), the infection was traced to a cow that was ill. In the Wilton outbreak (Conybeare and Thornton, 1938) and in the present one, however, the absence of evidence of illness among the cows presented the problem of finding the animal carrier. Conybeare and Thornton discovered the carrier by examining the antibody content of blood samples of individual cows. They found that about 50% of sera gave an agglutinin titre of 1 in 25. The sera of three cows gave a titre of 1 in 400 or higher, and the dung obtained from one of these cows yielded *S. dublin* on cultivation.

In the present outbreak the search for the carrier was made by determining the agglutinin content of the milk. It was found that milk from healthy cows did not contain any agglutinins for *S. dublin* and that even a low titre of agglutinins in milk was indicative of infection. It appears, therefore, that milk is a suitable material for serological tracing of carriers of *S. dublin* not only because it is more easily obtained than blood but also because non-specific agglutinins for *S. dublin* are not usually present.

How the milk became the vehicle of infection is a matter of conjecture. As the dung of the carrier cow contained the organism in large numbers it seems probable that the milk became contaminated as a result of faulty methods of production at the farm. On the other hand, although the milk of this cow was repeatedly examined with negative results, the possibility of intermittent excretion of *S. dublin* in the milk cannot be excluded.

### Summary

An outbreak of milk-borne gastro-enteritis due to *Salmonella dublin* is described. At least 162 people were affected. There were no deaths. The source of infection was an apparently healthy cow which was excreting large numbers of the organism in the dung. The carrier cow was identified by the agglutinin content of its milk. The milk of normal cows did not possess any agglutinins for *S. dublin*.

We are indebted to Dr. T. N. V. Potts, the County Medical Officer, and to Drs. D. F. Dobson and J. W. Forbes of Knaresborough for permission to publish an account of the outbreak. We thank the Divisional Inspector of the Ministry of Agriculture, Mr. W. T. MacGregor, and his assistant, Mr. J. M. McKellar; the County Sanitary Inspector, Mr. A. Brook; the local Sanitary Inspectors, Mr. H. Eatough and Mr. A. E. W. Lupton, for co-operation and assistance in the investigation; and also Mr. S. J. Denyer, Chief Technician at the County Laboratory, for technical assistance.

## THE EARLY TREATMENT OF WOUNDS OF THE CHEST IN THE MIDDLE EAST

BY

RONALD BODLEY SCOTT, D.M., F.R.C.P.

Temporary Lieut.-Col., R.A.M.C.; Officer in Charge of a Medical Division

The provision by the Army Medical Services of special team for the treatment of wounds of the chest demands an explanation, if not an apology, from the general physician who has the temerity to express his opinions on this subject. During the first and second battles of El Alamein, in July and Oct., 1942 a number of battle casualties with wounds of the chest were admitted to a general hospital, at that time less than a hundred miles behind the line. This hospital played the part of a casualty clearing station, although retaining greater facilities for investigation and treatment, and the management of these cases fell to my lot as medical specialist. Thus this paper records the experience of a general physician in the immediate treatment of thoracic casualties without the expert assistance of a thoracic surgeon. The problems were those commonly confronting the medical specialist in a casualty clearing station, and they differed from the problems of the thoracic team in the more leisured atmosphere of the base hospital. Time was limited: only treatment urgently indicated could be undertaken; and the immediate aim was to ensure that the patient had recovered sufficiently to withstand the rigours of evacuation to the chest centre.

### The Material

The material which forms the basis for these observations consists of 127 consecutive battle casualties with penetrating wounds of the chest. From the first battle wounded were admitted unselected, but from the second the hospital received only those whose condition was too precarious to allow of immediate evacuation. As this type of casualty is often gravely ill, chest wounds formed 13% of the second group and only 4.6% of the first. The majority had passed through a surgical unit, but treatment had commonly been confined to dressing and the administration of morphine. 46% were admitted within 41 hours and 72% within 72 hours of wounding. In all cases radiographs were taken, and it was possible to hold patients in hospital for as long as ten days when necessary; in these respects conditions differed from those usually operative in a casualty clearing station. No "follow-up" was practicable, but through the courtesy of Major A. Logan, R.A.M.C., O.C. No. 1 Surgical Team for Chest Surgery, the ultimate fate of the majority is known.

An analysis of the arms of the Service from which these casualties were drawn shows, as would be expected, that the infantry suffered most heavily. The composition of the series

TABLE I.—The Nature of Missile in 63 Cases of Penetrating Wound of the Chest

Nature of Missile	No. of Cases
Shell fragment	34 (54.0%)
Bullet (rifle, m.g., or revolver)	17 (27.0%)
Mortar-bomb fragment	6 (9.5%)
Land-mine fragment	3 (4.7%)
Aerial-bomb fragment	1 (1.6%)
Hand-grenade fragment	1 (1.6%)
Unexploded 50-mm. A.P. shell	1 (1.6%)

was: infantry, 72.5%; artillery, 13.4%; R.A.C., 3.9%; R.E. 3.9%; R.A.S.C., 3.9%; R.A.O.C., 1.6%; R.C.O.S., 0.8%. The nature of the missile in the 63 cases in which it was known is set out in Table I.

TABLE II.—The Intrathoracic Condition, on Admission to Hospital of 127 Cases of Penetrating Wounds of the Chest

Intrathoracic Condition	No. of Cases	No. Fatal
Haemothorax and haemopneumothorax	88 (69.4%)	5
Pneumothorax	5 (3.9%)	—
Pulmonary haemaloma	14 (11.0%)	—
Atelectasis	5 (3.9%)	—
Lung abscess	2 (1.6%)	1
Thoraco-abdominal injuries	13 (10.2%)	6

The patient with a penetrating wound of the chest presents two problems: the parietal breach of surface, and the visceral commotion caused by the missile. In this paper the second problem is considered first. The intrathoracic consequences of these wounds are summarized in Table II, and are discussed more fully in the following paragraphs.

#### Haemothorax and Haemopneumothorax

The common sequel of a penetrating wound of the thorax is effusion of blood into the pleural cavity. The blood is usually derived from the damaged lung, and in only one of these cases was there evidence of haemorrhage from the parietes. The injury to the lung is followed by the formation of a pulmonary haematoma; probably bleeding is seldom of long duration and is checked by pulmonary collapse unless it be due to rupture of a large vessel. The presence of blood in the pleural cavity provokes a serous reaction of varying magnitude; the degree as well as the variability of this process is shown by the haemoglobin content and erythrocyte counts of haemothorax fluids in Table III.

TABLE III.—*Haemoglobin Content and Erythrocyte Count of Haemothorax Fluid from 9 Cases aspirated on Various Days after Wounding*

Day after Wounding	Haemoglobin %	Erythrocytes (millions c.m.m.)
0	110	—
4	27	1.04
5	32	1.15
6	20	—
6	70	3.20
9	60	3.17
10	19	0.94
10	25	1.04
12	70	—

With the blood, in many cases, air will enter the pleural cavity, although absorption must commonly be rapid, for in this series only 14 showed the radiographic features of haemopneumothorax on admission to hospital. This air may enter the pleural space through either the parietal or the visceral wound; and of these 88 cases, the wounds of 32 were noted to be "sucking" shortly after infliction. Continued escape of air from a wound of the lung was rare, and only one showed, in addition to a haemothorax, the features of a tension pneumothorax.

At this early stage infection was the only serious complication. It occurred in nine of these 88 cases, and in each instance was established within seven days of wounding; in all but one an infected fluid was found at the first aspiration; in each case *Str. haemolyticus* was the responsible organism. So far as could be determined none became infected after evacuation. It is worthy of remark that the haemothorax became infected in eight of the 32 cases with "sucking" wounds and in only one of the remaining 56. In this latter case infection appeared after the first aspiration; later this patient died, and post-mortem examination showed two splintered ribs with bony fragments driven into the lung, and around these fragments a suppurating pulmonary haematoma. In this series a persistent pleuro-cutaneous communication was the most important single factor in determining infection. The only other significant complication was the presence, in one case, of mediastinal emphysema producing cervical venous engorgement but no symptoms.

The ideal of treatment in traumatic haemothorax is to empty the pleural cavity. The circumstances in which these patients were treated made it possible only to aspirate those who showed a mechanical indication or features suggestive of infection. Where there was no dyspnoea, fever, or tachycardia, and where the clinical and radiographic evidence pointed only to a small effusion, the patient was transferred to the special chest unit after four or five days. Aspiration was performed in 58 cases, and in many of these on several occasions. Air replacement was done only when indicated by symptoms arising during the procedure or to facilitate adequate aspiration. There was no suggestion that fresh haemorrhage was promoted by removal of large quantities of fluid within a day or two of wounding; this danger appears hypothetical. In one case 3.870 c.cm. was withdrawn without replacement by air and with no results other than beneficial. Although aspiration is usually a simple procedure, in a number of cases the fluid becomes loculated, and

radiographs show multiple fluid levels; in such it was often necessary to aspirate each loculus separately after location by radiograph. With infected haemothorax repeated aspiration was undertaken in the hope that the patient would improve enough to permit his transfer; but in five cases closed drainage by intercostal catheter was necessary.

In addition to aspiration in as many cases as circumstances allowed, all patients received 4 g. of sulphanilamide daily for six days and, when anaemia indicated, blood transfusion. It was possible to keep most cases in hospital for a week and to evacuate them only when temperature and pulse frequency had been normal for three or four days, and when orthopnoea had disappeared.

Of these 88 cases of haemothorax five were fatal before evacuation; so far as could be determined none died subsequently. The post-mortem findings in these fatal cases are given in Table IV.

TABLE IV.—*Post-mortem Findings in 5 Fatal Cases of Haemothorax*

Case	Day of Death after		Post-mortem Findings	Operation
	Wounding	Admission		
1	3	1	Haemothorax, bilateral, uninfected; perf. of bladder and small bowel	Laparotomy; repair
2	7	3	Haemothorax, right, infected; mediastinal emphysema left eye excised	Aspiration; excision left eye
3	13	6	Haemothorax, right, infected; streptococcal stomatitis	Aspiration; intercostal drainage
4	7	2	Haemothorax, right, infected; fracture 2nd and 3rd ribs, right; abscess right upper lobe	Aspiration
5	11	5	Haemothorax, left, infected; fracture sternum and 2nd rib, left; osteomyelitis of sternum	Aspiration

#### Pneumothorax

Five cases presented the clinical and radiographic features of pneumothorax without effusion of blood into the pleural space. Of these, only one resulted from a "sucking" wound; the remainder were due to small fragments of hand grenade or mortar bomb. In one case the wound of entry was in the neck, and the missile had traversed the mediastinum to rest in the right lung; in this instance mediastinal emphysema was associated with the pneumothorax. In only one was it necessary to withdraw air from the pleural cavity, and this procedure did not require repetition. The other patients did not need special treatment.

#### Pulmonary Haematoma

On x-ray examination 14 cases showed circumscribed shadows in the lung fields without evidence of pleural effusion. These opacities were roughly circular, and varied in diameter from 5 to 12 cm.; in the centre of so a metallic foreign body was visible. A pleural friction rub was heard in three cases seen shortly after wounding. Subsequent radiographs showed decrease in size and density of the shadow, and the appearances were interpreted as due to pulmonary haematomata. Two cases with large opacities showed later a transient jaundice without choloria, which was taken to indicate absorption of the effused blood. In one there was also a small pneumothorax with mediastinal emphysema. The distinction between pulmonary haematoma and haemothorax is difficult without radiography.

At the stage under consideration no treatment was required for the intrathoracic lesion. A sequel which had been met with in previous cases was the late development of a serous pleural effusion; it was noted in none of the present group while under my observation.

#### Lung Abscess

There were 2 examples of lung abscess in this series. It is likely that, in both, infected haematoma of the lung would describe the lesion more precisely; each was characterized by a fistulous communication between an infected parietal wound and the abscess cavity. Both patients had received extensive surgical toilet of the wound with suture in a forward unit; in one the lung had been secured to the chest wall. After admission to hospital, removal of sutures from the superficial wound led to improvement sufficient to permit evacuation. One patient died a month later.

### Atelectasis

It was a common experience to be called to see men with wounds of the chest, often associated with fracture of ribs or scapula, in whom urgent dyspnoea had convinced the medical officer that the pleura had been penetrated. In many no penetrating wound was found, but pain had led to shallow tachypnoea with voluntary suppression of cough; bronchial secretions had accumulated and rhonchi were audible throughout both lungs. In these cases local measures to relieve pain—of which the most important was removal of skin sutures—a dose of morphine, and persuasion to cough resulted in rapid emptying of the respiratory passages and the disappearance of distress. Untreated, atelectasis with subsequent infection was almost inevitable. In 5 cases with penetrating wounds the radiological findings were limited to those of collapse of one or other lower lobe. It was common, even with extensive intrathoracic damage, to find a high diaphragmatic shadow, and it seems likely that atelectasis from bronchial obstruction by aspirated blood or secretion is often a sequel of thoracic wounds. In three cases with haemothorax there was radio-graphic evidence of collapse of the contralateral lower lobe. Treatment of these five cases was confined to attempts to moderate the pain and to promote drainage by posture; infection was discouraged with sulphapyridine. In all five cases uneventful re-aeration was achieved.

This clinical picture is familiar in patients with simple fracture of a rib; its greater frequency and importance in those with wounds of the chest must serve for excuse if the point appears laboured. The chances of its occurrence can be minimized by relief of pain, and this should be achieved by local measures so far as is possible: a tightly sutured wound of the chest is often agonizing. Limitation of thoracic movement by exuberant strapping and prolonged inhibition of the cough reflex with morphine are undoubtedly important factors in its production.

### Thoraco-abdominal Injuries

In 13 cases the missile had traversed both the thoracic and the abdominal cavities; six of these patients died. Details are not pertinent; but, where the entry wound was left-sided, intestinal perforation and, consequently, death was frequent. Hernia through the diaphragmatic wound was seen twice; in three a missile lodged in the upper part of the right lobe of the liver had provoked a sero-sanguineous subphrenic effusion.

The present relevance of this group of cases lies in the diagnostic difficulty they offer. This difficulty is increased by the frequent association of simple penetrating wounds of the thorax with abdominal pain, rigidity, and tenderness—symptoms which in four cases of uncomplicated haemothorax led to fruitless laparotomy. Survival depends on early exploration, and when the entry wound is in the lower third of the chest suspicions of abdominal as well as of thoracic injuries should be aroused.

### Treatment of the Parietal Wound

The observations of a physician on this technical aspect of surgery will be regarded probably as worthless and certainly as impertinent. Thus it is with trepidation that these comments are offered, and because of the effect of the initial treatment of the parietal wound on the patient's subsequent course.

At this time there was little uniformity in the practice of surgeons in the forward areas, and Table V sets out the treatment

TABLE V—Initial Treatment of Parietal Wounds in 127 Penetrating Injuries of the Chest

Dressing	No. of Cases
Simple dressing	80 (62.9%)
Strapping over vaselined-gauze pack	9 (7.1%)
Excision and strapping over vaselined-gauze pack	8 (6.3%)
Suture without excision	11 (8.6%)
Excision and suture	10 (7.8%)
Excision and suture over vaselined-gauze pack	4 (3.2%)
Exploration, excision, and suture	5 (3.9%)

applied to the wounds in the present series before admission to hospital. Suture, with or without excision, was almost invariably followed by infection of the chest wall; it always led to a painful wound and the possibilities discussed under the heading of atelectasis. The practice latterly was to remove skin

sutures immediately the patient was admitted to hospital. In three instances a sutured wound broke down to leave a pleuro-cutaneous fistula; this was particularly likely to happen when the edges of the wound were approximated under tension and the intrapleural pressure was raised by a large haemothorax. Two of five cases in which the wounds were explored and sutured subsequently developed infection of the lung.

From experience with this group of cases it was concluded that the immediate treatment of the parietal wound should be as conservative as possible. The indications are to control haemorrhage from the chest wall and to close an open pneumothorax. If there is no serious haemorrhage and the wound is not "sucking," simple dressing is adequate; if the wound is "sucking" it should be closed by strapping over an air-tight pad and the intrapleural pressure lowered by aspiration of the haemothorax. The strapping should not hamper breathing by encompassing the whole chest.

In three cases which reached hospital with an infected haemothorax and a parietal wound that had broken down, immediate closed drainage through a catheter inserted at a distance from the wound was the only way the open pneumothorax could be controlled.

Immediate exploration should be limited to cases in which haemorrhage demands it, and perhaps to those in which fragments of bone have been driven into the lung; for this type of injury is likely to be followed by pulmonary suppuration. Uncritical exploration carries the additional danger of converting a closed haemothorax into an open haemopneumothorax—an event which invites the entry of infection.

### Summary

The management of 127 cases with penetrating wounds of the thorax, seen in a hospital working as a casualty clearing station, is described.

The intrathoracic sequels of these wounds were: haemothorax, 69.4%; pneumothorax, 3.9%; pulmonary haematoma, 11%; atelectasis, 3.9%; lung abscess, 1.6%; thoraco-abdominal injuries, 10.2%.

The early treatment of these conditions is discussed.

A plea is entered for the conservative treatment of the parietal thoracic wound in casualties of this type.

My thanks are due to the Director of Medical Services, Middle East Force, for permission to publish this paper.

## VISCERAL LEISHMANIASIS (KALA-AZAR) IN AN ADULT CONTRACTED IN MALTA

BY

F. E. LIPSCOMB, M.R.C.S., L.R.C.P., D.P.H., D.T.M.&H.  
Wing Commander, R.A.F.

AND

M. O. J. GIBSON, M.B., B.Chir., M.R.C.P.  
Temporary Squadron Leader, R.A.F.V.R.

Although the occurrence in adults of kala-azar contracted in Malta is categorically denied by Neumann (1930), four cases have been recorded in which the history and the demonstration of leishmania leave no possible doubt as to the identity of the disease or that it was contracted in Malta (Bassett-Smith, 1913, 1914; Kerr, 1918; Walker and Gibson, 1933; Gibson and O'Flynn, 1934). Four further cases have been reported in which the diagnosis was proved but in which the possibility of infection having occurred elsewhere than in Malta cannot be absolutely excluded (Ward, 1916; Kerr, 1918; Bassett-Smith, 1923).

A fifth case falling within the former category has recently been under our care in a Royal Air Force hospital in England, and appears worthy of record not so much on account of its rarity as because it serves to illustrate how an easy diagnosis can be missed through failure to bear in mind the possibility of tropical disease in men returning from service abroad. In this case the splenomegaly, anaemia, and leucopenia with a low-grade pyrexia in a patient recently returned from Malta immediately suggested leishmaniasis, and enabled a positive diagnosis to be made and treatment to be started without delay.

## Case Report

The patient was an air-gunner who in 1938, at the age of 20, proceeded to Malta, where he remained until he returned to this country at the end of his tour of duty in Jan., 1942. Although he had lived in Egypt and New Zealand in early childhood (1919 to 1926), he had not subsequently been out of England until his present tour, during which Malta was the only place visited. He remained in Malta until Dec., 1940, when he was admitted to hospital with a urethral discharge which proved to be non-gonococcal and very resistant to treatment. This persisted until July, 1941, and has relapsed periodically since then. In July, 1941, he started to have vague headaches, night sweats, and a troublesome cough, and was readmitted to hospital. Here he was found to have slight fever with a mild anaemia (4.6 millions) and leucopenia (5,800). Radiographs of the chest were normal, but it was noted that 2 st. in weight had been lost in the preceding four months. No definite diagnosis appears to have been made. It is of interest to note that during the preceding six months he had often been sleeping in air-raid shelters in various parts of the island without a sandfly net, that he recalls being repeatedly bitten by sandflies, and that he was in the habit of allowing a dog to sleep on his bed.

By the early autumn of 1941 he was flying again, but still felt "groggy," complaining of a dry irritating cough, frequent night sweats, catarrh, and tender epitrochlear, cervical, and inguinal glands. Several medical officers of all three fighting Services to whom he reported these symptoms did not apparently take them seriously, and he felt that he was suspected of malingering—so much so that he became embittered and lost confidence in himself, to the further detriment of his efficiency in the air.

After several short periods of non-effectiveness he returned direct to England at the end of his tour in Jan., 1942. During disembarkation leave he called in a local practitioner, who, after making an initial diagnosis of influenza, referred him to the medical consultant at a neighbouring civilian hospital. Here all investigations are stated to have proved negative (although a leucopenia of 5,600 with a relative lymphocytosis of 42% was recorded), and he was certified fit to return to duty.

On April 7, 1942, the patient was admitted to a Royal Air Force hospital for investigation. On admission he was seen to be pale, thin, worried-looking, and obviously ill. He had a dry irritating cough which kept him (and the rest of the ward) awake at night. The scanty sputum was repeatedly negative for tubercle bacilli, but there was clinical and radiological evidence of an imperfectly resolved right basal pneumonia. A few discrete cervical, epitrochlear, and inguinal glands were palpable and the gums were tender and bled easily. The spleen was enlarged three fingerbreadths below the costal margin, but was soft and the edge was not easily palpated. No other clinical abnormalities were found. There was a marked anaemia (3.5 millions, Hb 8.7 g.), and leucopenia (3,600) with a relative lymphocytosis of 47%. No leishmania or plasmodia were found in blood smears. The erythrocyte sedimentation rate (Westergren) was 60 mm. in the first hour. Agglutination tests against *Br. melitensis* and *Br. abortus*, Kahn test, Wassermann reaction, and gonococcal-fixation tests were all negative. Napier's formal-gel test became positive only after several hours. A provisional diagnosis of kala-azar was made.

After ten days of postural drainage the pneumonia had completely resolved, but pyrexia persisted, reaching 100–101° F. in the evening and falling to 98–99° F. in the morning. The typical "double peak" was rarely apparent, but the temperature was not recorded throughout the night.

On April 24 sternal puncture was performed and very numerous leishmania were found in the marrow smear, and were successfully cultured on Adler's medium. Leishmania were cultured also from venous blood at this time, although they were not found then or at any other period in blood smears even after prolonged search. At the same time a gland was removed from the groin, smears and sections of which revealed numerous leishmania. Sections of skin removed with the gland showed no leishmania.

From May 5 to 16 a course of 2.5 g. of neostam was given in daily intravenous injections, increasing from 0.05 g. to 0.3 g. The full course of 4.5 g. could not be completed owing to the distressing cough (chiefly at night), which was quite uncontrollable even with acroin. During the week following this course the fever declined somewhat, the spleen became appreciably harder and smaller, and the leucocyte count improved slightly (4,300). On May 29 numerous leishmania were still present in smears of sternal marrow, and so between June 6 and 25 a further 1.85 g. of neostam was administered in doses not exceeding 0.2 g. With this dosage the cough was a good deal less troublesome. On June 30 only a few degenerate leishmania were seen in sternal marrow and there was further slight improvement in the leucocyte count (4,800) and in the general clinical condition, although there was occasional evening pyrexia. A month's sick leave was then granted before deciding on further treatment.

On his return to hospital on Aug. 6 there was no appreciable change in the clinical condition. He reported three rigors and some bleeding from the gums during the preceding week. There was still slight evening pyrexia, with a definite dusky pigmentation of the temples. The blood picture had deteriorated (R.B.C. 3.3 millions, Hb 10.2 g., W.B.C. 2,600). His weight remained unchanged. On Aug. 16 a course of sodium antimony gluconate was started. Daily intravenous injections were given until a total of 86 c.cm. had been administered over a period of 15 days. No cough or other toxic manifestation was observed. Three weeks later the leucocyte count had risen to 5,000, but the anaemia persisted (3.4 millions). An occasional evening pyrexia was recorded, but 99° F. was never exceeded. Another month's sick leave was granted from Sept. 8.

On return from sick leave on Oct. 5 he felt considerably better and had played several games of tennis. A smear of lymph-gland juice was negative for leishmania and the leucocyte count had risen to 6,000, but as the anaemia persisted two pints of packed red cells were transfused on Oct. 15. This resulted in marked improvement, for when he was discharged to light duty on Nov. 4 the red cell count was 4.8 millions, Hb 13 g., and leucocytes 4,800. By Dec. 13 glands and spleen were still palpable and an occasional evening temperature not exceeding 99° F. had been recorded, but the leucocyte count had risen to 7,800 and there was no deterioration in the red cell count and haemoglobin.

The patient was seen again on Feb. 27, 1943. He had then been doing full ground duties for seven weeks and was feeling "perfectly fit." He looked well and had gained 20 lb. in weight. The edge of the spleen could just be felt and there was one palpable epitrochlear gland. The red cell count was unchanged at 4.79 millions, but the Hb had increased to 14.5 g. and the leucocyte count was 10,800 with a normal differential picture. The erythrocyte sedimentation rate (Westergren) was 2 mm. in the first hour. No leishmania were found in smears of peripheral blood or sternal marrow, and cultures from each remain sterile.

It now seems justifiable to regard the case as cured, but the patient is being kept under periodical observation. His return to full flying duties is unfortunately precluded by a dramatic complication, quite unconnected with the leishmaniasis or its treatment, which occurred four days after his resumption of ground duty on Nov. 4. On the afternoon of Nov. 8 he was readmitted to hospital unconscious and with a number of abrasions on the face and head. A history was given of his having suddenly fallen down while walking about the station. Further inquiries suggested epilepsy, and when consciousness was completely regained 48 hours later it was found that there was a short retrograde amnesia, and a history (previously unrevealed) of three similar episodes dating from the age of 14 was obtained. An electro-encephalogram two weeks later was grossly abnormal, and was stated to be typical of epilepsy.

## Summary

A case of visceral leishmaniasis (kala-azar) in an adult contracted in Malta is described.

We can trace only four recorded cases in adults whose infection cannot have occurred elsewhere than in Malta.

The syndrome of low-grade fever, cough, adenitis, splenomegaly, and leucopenia was well marked. Nevertheless the disease remained unrecognized and apparently unsuspected for many months both in Malta and after the patient's return to this country.

We express our thanks to Group Capt. W. E. Barnes, commanding the Royal Air Force hospital to which the patient was admitted, for his permission to publish the case; to the staff of the Wellcome Bureau of Scientific Research for their interest and advice; and to Messrs. Burroughs Wellcome for the supply of drugs.

Barth (Z. *Immunforsch.*, 1942, 101, 397) believes that through his culture method (agar with the blood of typhus cases) *Bac. proteus* X19 acquires special properties. Positive Weil-Felix reaction was obtained with the serum of guinea-pigs inoculated with such a strain, and even with the serum of guinea-pigs inoculated with genuine typhus virus. A positive Weil-Felix reaction occurs not only in the apparent animal disease but also in animals which develop a symptomless or abortive disease. On the basis of the animal experiments, the author believes it will be possible to carry out mass immunizations with this strain against typhus in man.

## Medical Memoranda

### An Improved Pappenheim Stain for Gonococci

Since the publication in the *B.M.J.* (1943, 1, 254) of a short article by me, "An Improved Pappenheim Stain for the Detection of Gonococci in Smears of Pus," I have had much correspondence concerning it. Many bacteriologists have obtained good results; others have experienced difficulties. These additional notes may therefore be helpful.

In most instances of difficulty the pyronine in the stain has been thought at fault, but I suggest that it is the methyl green. G. T. Gurr informs me that this dye is more concentrated now than before the war, and it is to be noted that the amount of methyl violet present as an impurity is variable. Gurr originally supplied green and blue-grey batches of methyl green. The blue-grey dye is now obsolete, and some batches apparently contained an excess of methyl violet. It should be observed that the green powder itself turns blue-grey in time on keeping and exposure. Some workers have got good results only by treating the methyl green twice or even three times, with chloroform, and this may be accounted for by the presence of an excess of methyl violet in the dye. I have not found more than one extraction necessary, but sometimes have produced a satisfactory stain only by reducing the concentration of the methyl green, and 0.1% may give a good result where 1.0% fails.

Pyronine from different sources has been found suitable, but some batches seem to have a lower dye content than others, as suggested by the differences in intensity of saturated solutions. Grübler's pyronine and pyronine (Conn), which is supplied by the National Aniline and Chemical Co., Inc., New York, yield excellent results.

If a satisfactory stain is not got by a reduction of the concentration of methyl green, proceed further by raising that of the pyronine. In some combinations of methyl green and pyronine, 2 g. or more of the latter may be necessary. A satisfactory stain is obtained when pyronine is present in an amount sufficient to colour the cytoplasm of mononuclear leucocytes in smears a faint pink.

In regard to the keeping quality of the modified Pappenheim stain, it is now possible to confirm that this is indefinite. I still have some prepared in April, 1943, which provides the results described in the original article.

The modified formula that follows is now recommended:

Methyl green (Gurr), chloroform-treated, 0.1-0.5%	100 c.cm.
Methyl alcohol, absolute	10 c.cm.
Pyronine G. (Conn, Grübler, B.D.H., or Gurr)	0.5 g. or more
Phenol	1.0 g.
Glycerol	20 c.cm.

**ADDENDUM.**—A bacteriologist in the Royal Navy has written me his appreciation of the stain, and has remarked that he stains directly with it and not as a counterstain in Gram's method. He claims a big saving in time and material by comparison with other stains for gonococci in smears, and has particularly noted that consistently good results are got even by laboratory assistants without any special staining experience. (I account for these results by stating that it is almost impossible to overstain.)

MAXWELL M. BARRITT, M.Sc., D.Bact., L.M.S.S.A.

City Laboratories, Liverpool.

### Long Survival after Hysterectomy for Chorion Epithelioma

The following case is described at the suggestion of Emeritus Professor Ranken Lyle, to whom I am indebted for the details of the previous treatment.

The patient, Mrs. A., aged 35, was admitted to the Royal Victoria Infirmary, Newcastle-upon-Tyne, under the care of Dr. Ranken Lyle on Aug. 27, 1910, suffering from hydatidiform mole. Curettage was performed by Dr. Lyle, and she was discharged six days later. Four months afterwards, on Jan. 6, 1911, she was readmitted, and stated that ever since the previous operation she had had a continuous small loss of blood from the vagina. The uterus was not grossly enlarged, and a diagnosis of retained products was made. On Jan. 9 she was again curetted by Dr. Lyle, who removed a few cysts from the uterus. During this operation the uterus was perforated, even though the greatest care was taken. Dr. Lyle considered this highly significant of the presence of chorion epithelioma, and performed an immediate vaginal hysterectomy. The left ovary, which was the size of a pigeon's egg, was removed, but the right, which was normal, was conserved. During the operation a further perforation occurred and a small piece of growth escaped. The uterus, which was slightly enlarged, showed a perforation through the fundus on removal. The patient was discharged from hospital

17 days later. The specimen was reported on by Dr. Stuart McDonald, who stated that the wall of the uterus was extensive, invaded by proliferating syncytial cells, and that numerous chorionic villi showing myxomatous degeneration were present. The condition was one of chorion epithelioma.

On Dec. 13, 1943, this patient, now aged 68, attended the outpatient department, bringing with her a letter she had received in 1924, asking her to attend the follow-up department. She explained that she had not been able to attend then owing to a domestic crisis, and apologized for keeping the department waiting 23 years. On examination I could detect no pelvic abnormality. There was no prolapse, and the vaginal vault was smooth and mobile. There were, however, signs of basal cystitis, for which she is now receiving treatment. She is very active, and still does all her own housework.

It would appear that freedom from recurrence for 33 years is sufficient to claim a complete cure.

Newcastle-upon-Tyne.

STANLEY WAY, M.R.C.O.G.

### An Unusual Swelling on Dorsum of Foot

This case is of interest, first because of the unusual finding at operation, and secondly because it illustrates the difficulty of making diagnoses in China, the land of surprises. The patient was a comparatively well-nourished Chinese soldier aged 48. He came complaining of a painful swelling on the dorsum of his left foot.

#### CASE HISTORY

The patient had had nothing the matter with his feet until three months before admission. Then, while marching, he experienced a sudden pain in the under-side of his left foot. At the time he was wearing straw sandals, which protected him from sharp flints, etc. When he examined his foot he found no injury, though the pain persisted; the site of this pain was just lateral to the ball of the foot. About a month later he noticed a swelling on the dorsum of the foot; the pain was now referred to this lump, which slowly increased in size.

Examination showed the patient to be well developed. His feet were typical of the ordinary Chinese buck private; the soles were well protected by a horny layer of thick skin, in which were the usual fissures. On the left dorsum an oval-shaped swelling about 1 in. by 2 in., lying in the long axis of the foot, could clearly be seen; it seemed to arise in the space between the extensor tendons of the big and first toes. On palpation it felt rather like a ganglion, as it was fluctuant; but somehow it gave one the feeling of more of soft rubber than of fluid; it was too tense to be a lipoma. Medical opinions were divided between a ganglion and some kind of tumour with cystic degeneration.

**Operation.**—Under spinal anaesthesia a longitudinal incision was made over the swelling. The tumour was adherent to the tendon sheath of extensor hallucis longus, while the tendon of extensor hallucis brevis appeared to go right through it. At this stage the macroscopic appearance resembled a sarcoma of the extensor sheath. Therefore the part of the tendon buried in the tumour was excised and an attempt was made to dissect out the base of the tumour and remove it *in toto*. Owing to its adherence to all near-by structures and the lack of any plane of cleavage, the dissection proved difficult. The cyst was punctured and a small amount of thin pus ran out. Finally, as this was almost completed, the whole cause of the trouble became apparent. A large thorn about 1½ in. long protruded from between the metacarpals into this mass of tumour. The thorn was quickly removed, and the area where it lay was curetted. After suturing the stump of the extensor hallucis brevis tendon to that of the longus, the skin was closed round a small rubber drain, which was removed next day. The wound healed by first intention.

The swelling was the result of a reactionary inflammatory process caused by a foreign body—namely, a thorn—which had pierced the sole of the foot three months previously. The thorn had passed upwards between the metatarsals of the big and first toes, and had become encapsulated in the space between the extensor tendons of those toes. The capsule was thick and adherent to the skin, to the sheaths of the extensor tendons, and to the interossei muscles. Inside the capsule was buff-coloured gelatinous degenerating matter. In the centre was a small space occupied by the thorn and a small quantity of grey pus. Owing to the lack of pathological facilities no further examination could be made.

I would like to thank Dr. Robert McClure of the Friends' Ambulance Unit, China Convoy, for his help in preparing this account.

JOHN F. THOMPSON, M.R.C.S.

Medical Officer, British Red Cross China Unit

F. L. Munro and H. W. Jones (*Amer. J. med. Sci.*, 1943, 26, 710), who record three cases in aviation cadets aged from 23 to 26, state that agranulocytosis due to sulphadiazine administration during acute infections may be benefited by subsequent dosage with the same drug. Spontaneous regeneration of polymorphonuclear leucocytes by the depressed bone marrow may occur during the administration of large amounts of sulphadiazine, even though this drug was responsible initially for the depression.

## Reviews

### BLOOD GROUPS AND TRANSFUSION

*Blood Groups and Transfusion.* By A. S. Wiener, M.D., serologist and bacteriologist in the office of the Chief Medical Examiner of New York City; head of Transfusion Division, Jewish Hospital of Brooklyn. Third edition. (Pp 438; illustrated 41s.) London: Baillière, Tindall and Cox 1943.

Since it first appeared in 1935 *Blood Groups and Blood Transfusion*, by Alexander S. Wiener, has been the standard work for all interested in the blood groups. There was a second edition in 1939. The outbreak of war and the widespread adoption of "blood banks" in civilian hospitals have led to a greatly increased interest in the subject and stimulated the author to produce a third edition, which has been largely rewritten. The new volume is intended to summarize present knowledge concerning the theory and technique of blood grouping, to present the applications in clinical, legal, and veterinary medicine and in anthropology, and to assemble and integrate the essential facts concerning the transfusion of whole blood, plasma, and serum.

There are two new chapters, one dealing with the transfusion of stored blood and blood derivatives and the other with the recently discovered Rh factor and its role in erythroblastosis foetalis. In discussing the preparation and use of stored blood and derivatives surprisingly little reference has been made to the experience gained in Europe. There is no reference to the work of Greaves and his colleagues at the Serum Drying Unit, Cambridge. Since 1941, in practice concentrated serum or plasma has been given by the usual methods and not by a syringe as recommended by Wiener. It would be extremely difficult to give an adequate dose to a restless shocked casualty with a syringe technique. The chapter dealing with the Rh factor is also disappointing. Our knowledge of this complex and intriguing factor is largely dependent upon the work of Wiener and his colleagues who first discovered it, and one had hoped for a rather more extensive summary of the present position, which is admittedly a constantly changing one. Experience with large-scale blood grouping in this country has demonstrated the wisdom of using as anti-A serum only serum which is known will react with known A,B cells. Wiener mentions the danger of mistaking AB blood of A,B subgroup for group B, but does not suggest the remedy that has proved so satisfactory over here. These criticisms, however, sink into insignificance before the debt all interested in the blood groups owe to Alexander Wiener.

### CHILD PSYCHOLOGY

*The Life of Childhood.* A Contribution to Analytical Psychology. By Michael Fordham, M.D. (Pp. 154; illustrated. 15s.) London: Kegan Paul, Trench, Trubner and Co. 1944.

Dr. Fordham is one of the small group of medical psychologists practising in this country who still follow the theories of Jung. He has devoted himself to the treatment of children, and in this book he gives to the world the results of his experience and demonstrates the application of the Jungian philosophy to that experience. His general findings and methods are very similar to those of other workers in child psychiatry, but, as he says, the interpretation of this material in terms of the various schools is rather like the translation of a classical passage into several different languages. Although the basis is common to all, the resultant translations may be very different. The danger is, of course, that the translation may become more concerned with the language into which the material is translated than with the material itself, and the less learned and instructed reader may wonder why it is necessary for the original passage, which he can understand well enough, to be translated at all.

The motif of the Jungian translation is the influence of the unconscious, especially that common universal part containing the archetypes of thought and feeling which influence the behaviour and reaction of both parents and child. The author points out that the child is and should be less conscious than the adult, and that treatment will therefore concern itself almost exclusively with the means whereby the child exteriorizes the unconscious—namely, in play, the drawing of pictures, in

fantasy and dream. The therapist must meet and co-operate with the child in this milieu.

Since so much of the child's behaviour is unconscious, his conduct, whether normal or abnormal, cannot be judged by adult standards. Adults will not be successful in their handling of the child, whether in the nursery or the school, if they are bound by rigid consciously determined rules and formulae. To be successful adult and child must meet on a common ground, and the child must be given an opportunity, generally through play, to work out his inner needs, which he himself does not fully understand. How far, therefore, the child's play should be interpreted to him in conscious formulae, in accordance with this or that school of thought, may be a matter of doubt.

This is an interesting book, sufficiently illustrated by clinical material and by reproductions of children's drawings. It is, moreover, much more readable and comprehensible than most books of the Jungian school, and is to be recommended to all who are interested in child psychiatry. To the ordinary parent the terminology and theory of analytical psychology will probably prove difficult and even misleading.

### RACE AND CRIME

*Race and Crime.* By Willem Adrian Bongers. Translated from the Dutch by Margaret Mathews Hordyk. (Pp. 130, 51.50 or 10s.) New York: Columbia University Press, London: Oxford University Press 1943

So many irrational and pernicious doctrines of race have been propagated during the last ten years that a scientific pronouncement on the connexion between race and crime is highly necessary. Prof. Bongers, who died of his own free will a few days after the German torrent had burst into his native country, had been the first leader of criminological thought in the Netherlands and had held the chair of sociology and criminology at the University of Amsterdam until his death. He was a specialist in the sound analysis of statistics, and the leading exponent of the philosophy of crime as a social and not a biological phenomenon. This is a translation of his last book, *Ras en Misdaad* which was published at Haarlem in 1939. He concludes that no definite results have been obtained in the study of the relationship between race and crime. The anthropology of races is still only in its inception, and the study of the anatomy of the brain cannot yet explain the differences among races which might exist in this regard; nor has scientific psychology gone much further in its study of races; and criminology is also badly informed, for criminal statistics do not as a rule give details of race. Criminality, moreover, he says, is not a characteristic like a round skull or blue eyes. Crime is always limited to a small number of individuals in a race. Often the criminological facts do not accord with what is psychologically known: the Nordic race is violent, but its aggressive criminality in the ordinary sense is small. The Jewish race is unusually subject to neurosis, but Jews commit few crimes of violence. Prof. Bongers emphatically denies any special predisposition for crime, and points out that predisposition is not predestination. His conclusions, based on a large number of case studies, are quite negative, but none the less possess high evidential value. His bibliography, amplified by the translator, is very full.

### Notes on Books

In *Man Studies Life: The Story of Biology* (Watts and Co.; 2s. 6d.) Mr. G. N. RIDLEY has attempted, with some success, to compress a large subject within the limit of a hundred small pages. After a short explanation of the science of biology he traces man's study of living organisms from the time of Hippocrates to the present day, devoting the greater part of the book to the advances of the last two centuries. The names and achievements of nearly 160 scientists are mentioned, so that some demand is made upon the absorptive powers of the reader. This book, which includes a glossary and a short well-chosen bibliography, provides a useful introduction to the study of biology.

The *Dentists Register* for 1944 has now been published for the Dental Board by Constable and Co., price 15s. The total number of names appearing on January 1 of this year is 15,404, being 212 more than the figure for 1943. All the new entries added were of persons registered as graduates or licentiates. During the past 20 years the total number on the *Dentists Register* has risen by fewer than 2,000 names.

## Preparations and Appliances

### A HAND RETRACTION PIECE

Major B. K. RANK, A.A.M.C., writes:

If the apparatus to be described would seem too simple or obvious, description is warranted by its value in operations on the palmar aspect of the hand where any elaborate dissection is indicated, more especially where excision and free grafting procedures are to be done, and also in many cases requiring extensive fasciectomy, tenolysis, tendon repairs, or grafts. The apparatus functions for maintaining hand retraction in a fixed posture, and it acts as a counter-pressure agent where pressure dressings are indicated.

FIG. 1.

*Description of Apparatus* (see Fig. 1): A wire grill (a) approximately 6 in. x 9 in. (e.g., that used as a toaster for a gas-stove) is fitted with corner legs (b) about 2 in. high. Distributed at intervals about its rim are several attachments (c) to act as hooks for rubber bands. A pack of sorbo rubber (d) about 1 in. thick is sewn to the upper surface of the grill. This is covered with a jaconet wrap (e) maintained by tapes to prevent undue soiling of the rubber with blood, etc. Several ordinary wide rubber bands complete the requirements. (Fragments of old rubber gloves can be used.)

*At Operation* (see Fig. 2) the hand is maintained in suitable posture for dissection by arrangement of the rubber bands

FIG. 2

between the hooks and the fingers; separate bands for the thumb, sometimes for the little finger or for any finger with fixed flexion deformity. This maintains traction on any scar and facilitates incisions and dissections. As scar is removed extension of the finger proceeds by the elastic traction. When the disability is corrected to the indications of the case the corrected posture is maintained by the traction, while patterns can be cut and a graft sutured in with the required finesse

without change of posture. Moreover, again without change of posture, the pressure dressing on a graft can be applied by including the whole apparatus in the pressure bandage (see Fig. 3). The size and arrangement of the stand permit of a pressure bandage in any or all directions across the palmar aspect of the hand and fingers so that pressure is evenly distributed by impression of the whole of the dorsum of the hand into the rubber pad. Finger abduction is arranged as desired by wool packed between the fingers. When the dressing is complete the rubber bands maintaining the finger posture can be slipped off or cut; though it is often convenient to leave them attached to the apparatus for replacement at subsequent dressings.

FIG. 3

*Advantages of the Apparatus.*—(1) Elaborate dissection can be carried out with finger traction maintained and without the cumbersome embarrassment of assistant hands or retractors. (2) An exact and constant posture of the hand can be maintained for long periods during grafting and dressing procedures. (3) Continued or intermittent traction can be arranged for tendon or joint contractions. (4) Pressure dressings are facilitated without undue pressure bearing on vulnerable points, such as the outer sides of the 2nd or 5th metacarpal heads, and without producing cupping of the palm, movement and partial loss of the graft about the inner side of the thenar or hypothenar region. These deficiencies are often seen with round-and-round crêpe bandages. (5) In post-operative treatment traction can be reapplied and posture need not be disturbed at subsequent dressings. (6) The apparatus is not an expendable entity.

### PROTEOLYSED LIVER

There are undoubtedly certain occasions on which it may be convenient to give liver extracts by mouth. Pernicious anaemia of pregnancy and pernicious anaemia with sensitivity to injected liver are examples. Owing to wartime shortages of alcohol and glycerin as well as of liver, oral extracts of liver have been officially banned, but the new process of preparation by means of papain digestion has allowed this ban to be relaxed. "Hepamino" (Evans) is the pioneer preparation of this type, and we can only regret that it has been given such a name. The proper title is proteolysed liver (extractum hepatis proteolysatum), which sufficiently distinguishes it from the dry and the liquid extracts of liver in the *British Pharmacopoeia*.

### SUPPLY OF THIOURACIL

Organon Laboratories, Ltd. (Brettenham House, Lancaster Place, W.C.2) announce that they have prepared thiouracil and several of its derivatives in tablets for oral use, and would welcome inquiries from medical men who would like to try these substances under suitably controlled conditions.

Genatosan Ltd. (Loughborough, Leicestershire) announce that they have now prepared thiouracil and that it is available in tablets containing  $1\frac{1}{2}$  grains for oral use in the treatment of thyrotoxicosis. They also supply thiourea in tablets of 5 grains for the same purpose.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 8 1944

## CROSS-INFECTION IN HOSPITALS

The treatment of illness in hospital rather than in the home has many advantages. It also has one serious drawback. This is the risk—sometimes slight, but in some classes of patient genuine and ever-present—of acquiring a fresh infection. To suppose that the great reforms of the latter part of the nineteenth century did away with this risk or even reduced it to minor proportions is a grave mistake. Indeed, next to chemotherapy, perhaps the most important line of medical advance during the past ten years has been the study of cross-infection; and the revelations made have been startling. Systematic bacteriological study, and more exact methods of identifying bacteria, notably the typing of streptococci which we owe to Griffith, have furnished proof that patients in open wards exchange bacteria freely. What was formerly regarded as a series of unfortunate and unconnected accidents is now recognized as a ward epidemic of haemolytic streptococcal infection, taking a variety of forms and possibly continuing with intermissions for months. Though this particular infection has aroused most interest because its migrations were formerly so obscure, it is only one of many which may be spread in a hospital ward. These include diphtheria and other infectious fevers, other infections of the air passages, dysentery, infantile diarrhoea, and other gastro-intestinal infections, various skin diseases, a troublesome example of which is pemphigus in newborn infants, conjunctivitis, and vulvo-vaginitis. The danger is greatest among children, particularly infants, and the ravages of enteritis have often been such that some authorities have questioned the wisdom of treating infants under ordinary hospital conditions at all.

The Committee on Preventive Medicine of the Medical Research Council appointed in 1939 a subcommittee on cross-infection in hospital wards, whose report has now been published.<sup>1</sup> A foreword by Sir Wilson Jameson explains that it was at first the purpose of this subcommittee to recommend structural changes in hospitals, but since these are now impracticable the purpose of this memorandum is to secure the desired results so far as may be possible without such changes. The first section—on the prevalence and consequences of cross-infection—is a concise and documented statement of what is now known about the acquisition in hospitals of infections of the respiratory and gastro-intestinal tracts, wounds, and skin and mucous membranes, and forms a serious indictment of present conditions. The second—on sources and modes of infection—illustrated by some telling original

diagrams, describes three main routes: droplets and drop-let nuclei, dust, and contact, the last being either direct or mediate via clothes, ward articles, food, or insects. These sections occupy six pages. The remaining twenty-two are devoted to practical instructions of every kind for the prevention and control of cross-infection. These range over many aspects of hospital work and are divided into those of general application and those called for in connexion with particular diseases. They include precise instructions for the use of disinfectants for many different purposes—the total of these specified, using either chemical disinfectants or heat, is 29—a full set of rules for barrier nursing, a set of special rules for maternity units, rules for a ward dressing team (based on those given in M.R.C. War Memorandum No. 6), and instructions for treating floors with spindle oil. Among "general administrative procedures" several recommendations are of interest. Hospital structure is the first concern, and here it is stated unequivocally that "the large open undivided ward must be considered as obsolete"; "nearly half the number of beds in a children's or infectious diseases hospital should be in individual cells and the remainder in small units." E.N.T. wards might have been mentioned as requiring the same subdivision. Swabs should be taken on admission from the nose and throat, and from the rectum in children with diarrhoea. Children likely to remain in hospital for some weeks should, if this has not been done, be immunized against diphtheria and possibly against whooping-cough. Visitors to children's wards should be discouraged, parents being afforded ready telephonic response to inquiries instead. That all visitors should wear masks, and, if supplies permit, gowns as well, is perhaps going rather far, but no doubt the public would get accustomed to it in time. Other sensible recommendations are that all kitchen staff should be instructed to report even minor gastro-intestinal disturbances, and that there should be a conspicuous notice in all water-closets: "Next wash your hands!"

The nurse is the person most closely concerned in these matters. A strong point is made of the need for giving the skilled nurse full opportunities for her proper work. This means relieving her of the domestic type of duty, both by labour-saving devices—several useful ones being specifically mentioned—and by allocating some of these duties to ward-maids. A nurse engaged in making up babies' feeds should not be required to change napkins, or otherwise deal with excreta or with septic conditions. Nurses should also receive both theoretical and practical instruction in bacteriology, a set of thirteen exercises for which is detailed in an appendix. This is perhaps the most difficult of all the recommendations to carry out—in large teaching hospitals because classes are themselves large, and in smaller because no teacher may be available. Where it has been done it has nevertheless been found well worth while.

This memorandum, if its value is realized, should have the largest circulation of any of the excellent war publications of the M.R.C. To ensure the application of its precepts a copy ought to be in the hands of every sister of every ward of almost every hospital in the country.

## DOCTOR AND CORONER

The coroner's office is very ancient, and more important than appears at first sight. His chief duty is to inquire into the cause of a death which may not have been from natural causes or has been attended by suspicious circumstances. His inquest is ordinarily public, and its result is published. He even holds an inquest on the body of a person on whom judicial sentence of death has been executed. He is therefore a powerful bulwark of liberty, for he opposes a constant obstacle to all those, both low and high, who would use murder to forward private ends or public policies. The medical practitioner, through his close professional contact with death, is in a position to give the coroner frequent and valuable help; and this help in the vast majority of cases he gladly gives. Now and again, however, friction arises between these two good public servants. The cause is usually an admirable but, as some think, a misplaced zeal on the coroner's part to inform himself more fully of deaths in hospital. This controversy is old, and is well annotated in "Taylor" and other textbooks of medical jurisprudence. Recently a coroner found it advisable, to enable him (as he judged) better to fulfil his duties, to request the medical staffs of hospitals in his district to report to him all deaths occurring in certain specified circumstances. These included deaths either within 24 hours of an anaesthetic or operation, or before consciousness was fully regained, and deaths within 24 hours of admission to hospital. Some medical officers took strong exception to the request, and consulted their defence societies. Accordingly the Medical Defence Union and the London and Counties Medical Protection Society, desiring to know the exact legal position, framed a set of questions for counsel's opinion. Mr. Roland Burrows, K.C., LL.D., who has had long experience of medical jurisprudence and is president of the Medico-Legal Society, composed an opinion which, in the absence of any judicial authority on these questions, commands the highest respect.

A number of the questions dealt with the hypothetical legal duty of the doctor to report deaths to the coroner. Mr. Burrows answered all these questions with the surprising but convincingly argued opinion that no citizen has any duty to report to the coroner any death at all. Surprisingly, belief that some such duty existed at common law was almost if not quite unanimous. *Servis on Coroners*, the best-known textbook, lays down that in all cases of sudden death, or death in suspicious circumstances, where the duty of informing the coroner is not by statute imposed upon any particular person, it is the duty of those about the deceased to give immediate notice to the coroner or his officer, or to the nearest officer of police, who then communicates with the coroner. A Home Office circular issued in 1927, doubtless with the approval of the legal advisers to the Secretary of State, said that if the medical practitioner has any reason to believe that an inquest may be necessary it is "of course" his common-law duty as one of those about the deceased to notify the coroner, his officer, or the police, but he must still certify the cause of death. Mr. Burrows, however, points out that the test of

an alleged legal duty is whether it can be enforced. When ever proceedings have been taken, the offence charged has been that of "obstructing a coroner in his duty." To prove this the prosecution must show that the coroner owed a duty to hold an inquest, and that the accused did something with the intention of preventing the inquest from being held. There is no trace of an individual responsibility based merely on a failure to give information. The doctor is for this purpose an ordinary citizen, as (except in a few special cases, such as death in a mental hospital or a retreat for habitual drunkards) he owes no statutory duty to report a death to the coroner. By the Births and Deaths Registration Act, 1926, Sect. 6, the medical practitioner who has attended the deceased in his last illness and can form an opinion on the cause of death must send the certificate to the registrar, and the registrar must report to the coroner any death covered by the long and detailed list contained in the Registration Regulations (S.R.O. 1927, No. 485), which includes the absence of a certificate. Mr. Burrows therefore thinks that the law relies upon the rules governing registration and burial to ensure that the coroner shall receive information, and leaves to the individual conscience of the citizen the decision whether he shall volunteer information.

In asking Mr. Roland Burrows whether a practitioner was entitled to perform a post-mortem examination in given circumstances without the consent of the coroner, the defence societies were evidently misunderstanding the position. Mr. Burrows replied that the coroner's consent is never necessary, but that he may direct or request a necropsy under the Coroners (Amendment) Act, 1926. For the rest he gave the interesting opinion that the only examination that can lawfully be made, is one under Sect. 7 or 8 of the Anatomy Act, 1932, the legality of which does not depend on whether the cause of death is known or in doubt. This, he explained, is not a full post-mortem examination but an "anatomical" examination, which he takes to mean a full visual examination of all parts of the body. Doubtless many medical practitioners would have liked him to enlarge a little on this question, for his words appear to imply that the universal practice in hospitals of holding post-mortem examinations for scientific purposes is illegal. The summary which he authorized and which appeared in the *Journal* for Nov. 27, 1943 (p. 694), makes the matter easier: a practitioner may, he says, make a post-mortem examination with the consent of the deceased's relatives, whether or not he knows the cause of death, unless by so doing he knowingly hinders the coroner in carrying out his duties. As soon, however, as it comes to his knowledge that the coroner has been informed from any source touching the death he should on no account make any examination without instruction from the coroner. The coroner's consent, in other words, may technically not be necessary, but it is sometimes just as well to get his *nihil obstat*.

At law, then, if Mr. Burrows is right (and in the absence of authority it is really an open question), the doctor need not report any death to the coroner, but should merely certify according to the Registration Acts and send the certificate to the registrar. Socially and morally, however,

he may often owe a duty to inform the coroner direct. Both the defence societies and Mr. Burrows emphasize this far more important aspect of the matter. Doctor and coroner are alike servants of the public, and their service will be better if they co-operate. The registrar is not a swift channel of information, nor is he medically qualified. To leave him to sift the matter means further delay and distress to relatives who probably have enough to bear already. The custom whereby the doctor informs the coroner direct of facts which should put him on inquiry is a good one, and Mr. Burrows's opinion does not suggest that it should be modified by a hair's breadth. Harmony between the two will best be maintained if the doctor gives the coroner all the information he feels he can properly give, and the coroner respects the doctor's reasons for wishing to set limits to this concession.

### PENICILLIN IN WAR WOUNDS

One reason given for the present non-availability of penicillin to civilians is the prior claim of battle casualties. That penicillin well used at a reasonably early stage can largely overcome sepsis in battle wounds is evident from the report of Florey and Cairns on their experience in Tunisia last summer, which was reviewed in this *Journal* a few months ago.<sup>1</sup> It is evidently intended that as many casualties as possible in forthcoming operations shall have the benefit of this discovery, since the Medical Research Council has now published a memorandum of practical instructions solely for treating battle wounds of various kinds with penicillin.<sup>2</sup> This has been drawn up by the Penicillin Clinical Trials Committee, who acknowledge their indebtedness to Florey and Cairns for much of the essential information on the technique of actual treatment, and indeed quote freely from the War Office report to which we have already referred. This is the first manual of instructions for penicillin treatment to become generally available, and may be found useful to those so fortunate as to have penicillin at their disposal for other purposes, since some of the information given is necessary for any form of treatment. The memorandum consists of three parts. The first describes the preparation of penicillin for use: the solid as supplied may be either diluted with sulphanilamide as a powder, dissolved in sterile water to furnish solutions of various strengths, or incorporated in a cream. It is emphasized that penicillin is unstable, and various precautions are needed both to ensure that activity shall not be lost and to prevent contamination. The instructions for actual use reproduce in the main the recommendations of Florey and Cairns for the treatment of soft-tissue wounds and compound fractures—namely, suture and local treatment for the former, and suture when possible and a short course of systemic treatment for the latter. Special types of wound and of wound infection, and burns, are dealt with more briefly. A final section deals fully with the laboratory control of treatment. This involves determining the susceptibility of the bacteria concerned to penicillin, estimating the penicillin content of wound fluid after local treatment, estimating the penicillin content of blood, and titrating the potency of penicillin itself should this be suspect. Several methods for some of these proceedings are given. There is a useful list of classified references to the principal papers on the subject, with their titles.

### CLASSIFICATION OF DISEASES AND INJURIES

The truism that the more accurate the data submitted to analysis the greater the probability that a skilful analyst will reach accurate conclusions applies with peculiar force to the work of a medical statistician, because his data consist of other men's opinions on the correctness of which he may doubt but must, in his arithmetical operations, assume. It is true, of course, that statisticians of genius, the Graunts and Fatts, have often profitably used data which duller men supposed not to be worth the trouble of analysing, and also true, as Farr said, that an elaborate nomenclature is not enough to guarantee exact statistical data. But in this and other civilized countries a large proportion of the graver forms of sickness and injury come under observation in hospitals and institutions, in which the combined skills of experts in different branches of medical knowledge enable a precise statement of the facts to be made. The object of the volume published by the Medical Research Council<sup>1</sup> is to make data obtained in this way available for the advancement of medical science by statistical analysis. A work of this kind cannot make a wide appeal; a reader who opens it at random and discovers that a "soldier, with an infected ununited compound fracture of the humerus (the infection being staphylococcal) consequent on an accident while playing football on leave, is coded I=84(3V)2VX-4X: II=686-2, or, on machine

XX

VV

cards, I=8 4 3 2 4: II=686-2," may not be deeply interested. He should, however, reflect that the compilation of a dictionary is of great value to those who have to translate from one language into another, although the result is of little interest to others. The analogy is incomplete, because in the case before us there are not two but three operations: translation from a language we know into a strange language; grouping of the translated words; presentation of the results in the known language.

Only a small number of medical readers will wish or are even competent to criticize the first operation in this series. Many medical readers are, however, competent to criticize the preliminary choice of terms to be translated. Both in the preface and in the body of the work the provisional nature of the classification is emphasized.

"The present classification must be regarded as experimental, and liable to be modified after practical trial. Expert opinions regarding heart diseases and psychoneuroses, for example, are so conflicting that only tentative groupings could be made, and the classification of heart diseases on pp. 45 and 46 below was framed deliberately so as to obtain some of the information needed before a satisfactory grouping can be evolved."

We have no doubt that the invitation given in this passage will be accepted. One caution may be offered to those who accept it. The final object of this preparation is statistical—viz., the elucidation of group phenomena. This means that a number of individual records are merged to provide some index or characteristic of the group, with the consequence that some personal differentiae are lost. All soldiers with infected ununited compound fractures of the humerus, the infection of staphylococcal origin consequent on football accidents sustained on leave will be coded as described, although no doubt an expert could classify these fractures and the circumstances under which they were sustained into many subgroups. But there is no end to this process, and eventually one may find that the number of groups is coextensive with the number of individuals—the heap of stones has been resolved into its separate stones. One is reminded of Walter Bagehot's defence of party government: that, without it, to each motion in the House of

Commons there would be 640 amendments, none of which would be carried, nor the original motion. That is a reason for thinking carefully before adding to the list of diagnoses to be translated. The introduction of machinery has enormously reduced the time and labour required for tabulation; and, we may hope, team work will enormously increase the data available for tabulation. It is not, however, unduly pessimistic to hold that, with this list as it stands and even nation-wide data, a very long time must pass before complete tabulation would be a statistically profitable enterprise.

The volume is a valuable contribution to the advancement of science; all those intimately associated with the work will approve the expression of indebtedness to Dr. Percy Stocks and Dr. Robb-Smith recorded on the back of the title-page.

### TRAUMATIC DEAFNESS

Loss of hearing due to acoustic trauma is recognized as a clinical entity. Since some persons are more liable to traumatic deafness than others, the elimination of such predisposed persons from noisy industry might be an effective prophylactic measure. Persons with a family history of hereditary deafness are likely to suffer, and so also are those with a scarred membrana tympani. Conduction deafness should be a bar to work in noisy occupations, as fixation of the stapes increases the intensity of sounds by bone conduction. It has been suggested that a test of threshold value taken before and again thirty seconds after exposure to an 80-decibel tone at the same frequency (256 dv.) for five minutes might give an indication of individual resistance to the effect of loud sounds. To put this into practice Wilson<sup>1</sup> made observations on 85 recruits at an Army training centre before and after firing. In 27 of these there was a rise in the threshold for hearing after subjection to the fatiguing tone, while in 58 there was not. Twenty-one out of the 27 showed a hearing loss on return from firing later, while 6 had the same threshold before and after firing. Ten only of the 58 who had not been affected by the fatiguing tone had a rise in threshold after firing, while 48 did not. There were thus 31 cases with a loss of hearing after firing, and on re-examination one or two weeks later 15 out of 16 re-examined still showed some loss. These results, which may be found analysed in more detail in the original paper by Wilson, give support to the argument that impaired hearing predisposes to an increased susceptibility to acoustic trauma, and it also appears that the ears of some persons are more easily fatigued and are more susceptible to acoustic trauma than those of others. It is suggested that this relation between a liability to auditory fatigue and to traumatic deafness may be employed as a test for predisposition to the latter. In this way susceptible individuals may be recognized and eliminated from occupations in which noise may have an injurious effect on the hearing.

### LUNG FLUKES

Human cases of paragonimiasis appear to be rarities in countries other than China, Formosa, Japan, and the Philippine Islands; and the recent record of an indigenous case in Nigeria<sup>2</sup> is of interest both in extending the known distribution of *Paragonimus westernmanii* and in reminding the medical profession that either or both pulmonary and cerebral symptoms may be caused by this parasite. In the Nigerian case pus from a cyst in the left sterno-mastoid contained the characteristic operculated ova, while none were seen in the sputum. Apparently the flukes had

penetrated the central nervous system eleven years previously, when a fit was followed by symptoms of cerebral lesions. The other African records are from Tripoli, the British Cameroons, the Belgian Congo, and from a much-travelled Arab. No cases have been reported from European countries, though the possibility of its becoming endemic is now present with the invasion of the rivers by the mitten crab, *Eriocheir sinensis*, the second intermediate host. As in America, another snail might deputize for *Melania* (the first intermediate host in the Far East), and a reservoir host, the musk rat, is already present. *Paragonimus* ova, expectorated in sputum or passed in the faeces, on reaching the snail hatch out and multiply internally, resulting in a large number of active cercariae. These escape into the water and bore their way into certain species of crustacea, where they encyst. It is this stage which is infective to man, when crayfish or crabs are eaten raw or undercooked, and to the reservoir hosts—both wild and domestic carnivores such as the musk rat, wild cat, beaver, mink, fox, and tiger, or the rat, cat, dog, and pig. In America, where exceedingly few human cases have been reported, *Paragonimus* has been found in the mink, cat, and dog in many areas. With a review of the world distribution of *Paragonimus*, LaRue and Ameel<sup>3</sup> report its occurrence in crayfish purchased in widely separated localities in North America. In living crayfish the encysted cercariae were recognizable to the naked eye because of their white excretory bladders, in contrast to the yellowish host tissue, and were most numerous around the dorsally situated heart. In preserved crayfish the hearts required to be cleared in phenol in order to reveal the cysts. If a crustacean is very heavily parasitized it is possible that encysted cercariae may fall off the gills and be swallowed in drinking-water. This seems the only explanation of the source of human paragonimiasis in countries where crustacea are not eaten raw or undercooked. A single case of paragonimiasis in a New Britain native was reported<sup>4</sup> before the Japanese invasion, so that it is probable that suitable intermediate hosts are present. A few cases have been reported in Sumatra, Java, Indo-China, Malaya, and India.

Haemoptysis occurs in a small proportion of cases only, and the diagnosis of paragonimiasis depends on the finding of operculated ova in sputum, faeces, or pus from cysts. Small brown oval worms are found in necropsy material and are usually most numerous in the lungs. X-ray examinations are not regarded as a satisfactory diagnosis. The most efficacious treatment so far reported<sup>5</sup> resulted in four cases showing no recurrence of symptoms and two cases relapsing five months after intramuscular injections of prontosil (2.5% to a total of 60 to 165 c.cm.) with intravenous emetine hydrochloride (4% to a total of 12 to 23.5 c.cm.) over a period of 7 to 17 days.

Mr. Somerville Hastings, consulting surgeon to the Ear and Throat Department of the Middlesex Hospital, has been elected Chairman of the London County Council. Mr. Hastings has been Chairman of the Hospitals and Medical Services Committee of the L.C.C. for the past ten years.

Dr. T. L. Hardy will deliver the Croonian Lectures before the Royal College of Physicians of London on Tuesday, May 9, and Thursday, May 11, at 4 p.m., at the College, Pall Mall East. Subject: "Order and Disorder in the Large Intestine."

# THE THERAPY OF ASTHMA

The treatment of asthma resolves itself into a consideration of underlying factors and causes. Often in **ASTHMA** the underlying cause is not discoverable or changes from time to time—now irritant dusts, now bacterial infection, etc. The underlying factor is fortunately always the same—bronchospasm.

Thus sometimes causative agents can be removed or mitigated but always the underlying factor—bronchospasm—can be treated, successfully, with **FELSOL**.

Most cases of Asthma are chronic and demand patience in treatment—persistence with **FELSOL** will yield the highest possible percentage of successes.

## TRADE 'DECICAIN' MARK

(The Original Product)

### Brand of AMETHOCAINE HYDROCHLORIDE

The anæsthetic action of 'Decicain' is ten times that of cocaine, and it may be used therefore in correspondingly weaker dilutions in a wide range of indications, notably otolaryngology and ophthalmology. Solutions of 'Decicain' are stable and can be sterilised by boiling.

Issued in tablets of gr 1½ in tubes of 10, and solution 2%, bottles of 1 oz

## TRADE 'FRANOL' MARK

### Brand of ANTI-ASTHMATIC

'Franol' combines antispasmodics known to have a relaxing action on the musculature of the bronchi, phenobarbitone, theophylline and ephedrine. Results of extensive clinical trials indicate that symptomatic relief was obtained in a very fair percentage of cases of bronchial asthma of allergic origin.

Issued in tablets, in tubes of 20 and bottles of 100

## TRADE 'ANAESTHESIN' MARK THROAT TABLETS

### Brand of BENZOCAINE

This tablet combines sodium borate and menthol with a local anæsthetic in the form of ethyl-p-aminobenzoate. The active organic compound acts as a surface analgesic and anæsthetic, and benumbs the part which it bathes. Indicated pre- and post-operatively in oral surgery and in painful affections of the tongue.

Issued in tablets, in bottles of 20 and 100 (Prices reduced recently)

Made in England.

BAYER PRODUCTS LTD. AFRICA HOUSE KINGSWAY LONDON W.C.2

## PHENIODOL B.D.H.

$\alpha$ -Phenyl- $\beta$ -(hydroxy-3:5-diiodophenyl) propionic acid

*A new Cholecystographic Agent*

The incidence of untoward symptoms is appreciably less following the administration of Pheniodol B.D.H. than when iodophthalein is employed. Further, Pheniodol B.D.H. is concentrated in the normal gall-bladder after oral administration at least as well as iodophthalein when given intravenously.

Pheniodol Meal B.D.H. (containing 50 per cent. of Pheniodol B.D.H.), which mixes readily with water to form a suspension which can be taken as a draught, is available in single tubes containing one dose and in boxes of six tubes.

*Details of dosage and other relevant information will be gladly supplied on request.*

THE BRITISH DRUG HOUSES LTD. LONDON N.1

## 'NEPTAL'

TRADE MARK

BRAND

### mercuramide with theophylline

A new packing of this mercurial diuretic has recently been introduced. It is a more dilute solution for administration by the intravenous route only and is supplied in ampoules of 5 and 10 c.c., these being equivalent to the 1 and 2 c.c. ampoules formerly employed for the purpose. The latter continue to be supplied for use by the intramuscular route and the strength of this solution remains the same, namely 9.2 per cent. w/v mercuramide and 5 per cent. w/v theophylline.

For maintaining patients oedema-free after a course of injections or in the more severe cases for prolonging the interval between injections 'Neptal' is administered orally, for which purpose tablets are available containing mercuramide 0.16 grammie and theophylline 0.08 grammie in each. Owing to the convenience and effectiveness of the oral route rectal administration by means of suppositories is obsolescent.

**SUPPLIES:** 'Neptal' intramuscular solution is supplied in 1 and 2 c.c. ampoules and intravenous solution in 5 and 10 c.c. ampoules, all being available in boxes of 6 and 25 ampoules. The tablets are issued in bottles of 12, 25 and 100.

## MANAGEMENT OF A FIELD SURGICAL UNIT

BY

J. HOWELL, M.B., B.Ch.

*Major, R.A.M.C.; Specialist in Anaesthetics*

AND

B. McN. TRUSCOTT, M.B., B.S., F.R.C.S.

*Major, R.A.M.C.(T.); Surgical Specialist*

Much attention has been paid at discussions and in the journals to the purely operative side of forward surgery, but in our opinion the other side, which may be termed loosely the "running of the unit," has been somewhat neglected. When taking a new Field Surgical Unit into the forward areas there are many pitfalls into which the unwary may stumble but which with forewarning can be easily avoided.

The unit to which we belong has been working for a year and has functioned through two campaigns involving three different types of military operations. It is based on the Middle East establishment and carries, in addition to the surgeon and anaesthetist, a corporal operating-room assistant, a lance-corporal clerk, two nursing orderlies, a batman, and two R.A.S.C. drivers. The Middle East scale of equipment is sufficient to provide a complete operating team, but all accommodation of the patients before and after operation and all nursing are provided by the medical formation to which the unit is attached. This equipment can be summarized in the following way. Two tents, one large and one small, are used as a theatre and a sterilizing room. Enough instruments are carried to tackle any case that may arise, but the numbers of these instruments are kept down to a reasonable figure. Tents are also carried to accommodate the personnel. In addition, a reserve of stores—particularly plaster, anaesthetics, and dressings—is taken to deal with about a hundred cases without replenishment. With these provisions a Field Surgical Unit can join a Field Ambulance, a Field Dressing Station, or a Casualty Clearing Station, and provide or supplement the surgical facilities of that unit.

From December, 1942, to June, 1943, our unit was with the Eighth Army during the advance to Tripoli and Tunis. In September, 1943, it accompanied the invasion forces to Salerno. Here the work was of two types—the phase of forming and consolidating the bridgehead and then the subsequent advance through Italy. Under these three varying conditions it has been found that the basic principles—partly learnt by bitter experience and partly handed on to us by our predecessors during the long months of fighting in the desert—have not been found wanting. Minor alterations only have been necessary to cope with the changing conditions.

These principles may be described under the following headings: (1) co-operation with the parent unit; (2) minimizing fatigue; (3) note-recording; (4) extra equipment and comforts.

## Co-operation with the Parent Unit

A Field Surgical Unit can be regarded as a graft on to a larger medical formation, and, like a graft, retains its entity but has to fit in with the host; unlike a graft, the host may be changed repeatedly, and the unit must be self-contained but adaptable. We feel that it should be an operating unit, pure and simple, which can handle its own equipment without calling on any outside aid. There is a danger that over-elaboration and attempts to increase the facilities carried and the scope of its capabilities may cause this essential to be forgotten. No host unit welcomes a request for help in setting up a theatre when their personnel are fully engaged in their proper and routine duties. Not all units to which one may be attached will have had previous experience of working with a surgical unit, and, even if they have, every team has its own peculiarities and foibles. We have found every unit with which we have worked more than willing to fall in with the suggestions offered. If these are made right at the beginning co-operation starts on the proper basis and minor frictions and irritations are avoided. There are several points that are always well worth stressing, and they can be divided into two categories—pre-operative and post-operative.

In the pre-operation or resuscitation ward, quite apart from the treatment of shock, much valuable time can be saved by the proper preparation of the patient before he goes into the theatre. This does not mean the whole routine of shaving and washing the affected area—indeed, this is better done under the anaesthetic—but rather attention to the sufficient removal of clothing, the adjustment of clean blankets, and adequate premedication. It is not enough to cut away the sleeve of a shirt or the leg of a trouser; each garment must be removed completely. A blanket which is heavily soiled with blood is a hindrance to resuscitation and a discomfort to the patient after operation; it is much better removed in the pre-operation ward than in the theatre.

Regular pulse and blood-pressure readings form an invaluable guide in assessing the response to resuscitation and the optimum time for operation. Intelligent orderlies can easily be trained to do this and record the readings for each case of any severity. In carrying the patient to and from the theatre we have used our R.A.S.C. personnel. Once they are trained in the routine it makes for greater speed and efficiency. The situation of the pre-operation ward is important. It must be as close as possible to the theatre: directly adjoining it is the ideal. The surgeon will need to make frequent visits between cases to watch both the work still to be done and the progress of the cases still being resuscitated. If these visits involve a long walk down a dark corridor or across the open, tripping over guy ropes at night, there will be increased fatigue, waste and loss of time. It is noticeable how slowly one accommodates to the dark after concentrated work in the theatre.

The post-operation ward, if accommodation allows, should be reserved for the seriously wounded cases which will need special care and attention. If every minor case is sent there, awaiting evacuation, the nursing staff will be unable to devote proper time to the more difficult patients. We have made it a rule to write post-operation instructions in fair detail on the Field Medical Card for all serious cases. Until the orderlies have become accustomed to the methods and routine, frequent visits have to be made to the ward to ensure that all instructions are being carried out. Although the parent unit will usually detail an officer to look after the cases after operation, the responsibility naturally rests with the surgeon.

During a prolonged spell of work there is a great temptation to get away to rest or bed when a lull occurs, and the anxieties and repeated requests for opinion and advice from a ward full of "belly" cases can become a great strain. This almost hour-to-hour supervision must be done, however, if tragedies are to be avoided.

We have found that the orderlies are all keen to learn and soon develop an appreciation of the various procedures. Once this appreciation has been achieved things are easier, but they must be watched very carefully during the interim stage.

## Minimizing Fatigue

One of the most pressing problems of forward surgery is the mental and physical fatigue that is inevitable during a heavy rush of casualties extending over several days. This is especially so when the team is the only operating unit attached to a Field Ambulance or Field Dressing Station. When there is more than one team the onset of fatigue can be postponed by adopting the shift system. An operating team can carry on for many hours before the members are so tired that they have to stop from sheer exhaustion, but there is a stage when judgment and operative skill fall far below a satisfactory standard. This acute fatigue must be distinguished from the chronic variety which comes on insidiously after weeks of steady and unrelieved operating.

There are several ways in which the powers of the team can be conserved. It must be realized that it is not only the surgeon who bears the strain but the team as a whole. The operating-room staff will have to spend much time preparing the theatre before operating and cleaning up after the last case. Probably the most important factor is the strict working to a routine. Every man should have his place in the scheme and keep that place. The surgeon will then be able to relax until everything is ready for the start of the actual operation. In a short time the orderlies become remarkably efficient, not only in preparing the patient but also in spotting unadvertised

wounds and subcutaneous foreign bodies. It should only be necessary to tell the O.R.A. the nature of the next case for him to have ready all the routine splinting, plaster slabs, and bandages that will be required. To achieve this routine it is as well to practise during any preliminary training period many of the more important duties. This should include such things as tent-pitching, the off-loading and loading of lorries, the setting up of the theatre, and the preparation and application of some of the larger and more intricate plasters.

Any extraneous noise is distracting, and there should always be at least a short passage and a double screen between the theatre and the ward. While visitors are welcome, we insisted that the numbers of spectators and helpers should be kept down to a minimum. If the case is not a serious one the instruments are used on the cafeteria system: a complete set is laid out on the Mayo table and sufficient taken for the case; this reduces sterilization as much as possible. On the ordinary case we have not found it necessary to have a "washed-up" assistant. With the limited numbers of orderlies available it is better to keep them free to help in moving the patient, put on bandages, or clean and sterilize the instruments used on the previous case. Hot sweet tea is excellent for reviving a flagging team, and a constant supply between cases is most welcome and valuable. (A minor point worth mentioning in this connexion is the desirability of having a latrine fairly close to the theatre.) There is some difference of opinion on the question of using one or two tables. A team working with two tables can achieve a faster rate of turnover but there is a greater strain on all the orderlies. This method is apt to introduce an atmosphere of rush and hurry that must be avoided at all costs. There is a limit to the number of cases that can be cleared in a given time, and working with two tables is liable, in our opinion, to hasten the onset of the danger-point in fatigue.

When working as a solo team it may be difficult to get enough time for sleep. Every lull must be utilized to the full, and even then it may become a matter of short sleeps at irregular intervals. It is important that the men should have sleeping quarters which are close to the theatre and quiet at all times. Rest periods must not be disturbed to allow the men to attend the routine unit meal-times, and the parent unit will usually arrange that something is available at the cook-house at any time. Much of the strain falls on the O.R.A., and we have found that he will benefit by a morning or afternoon right away from the camp every now and then. A trip to the medical stores or with a patient to another medical unit makes a good break. This has the further advantage that it accustoms the other orderlies to working without him, a safeguard in the event of his becoming a casualty.

#### Note-recording

It need scarcely be pointed out that operation notes must be full, accurate, and easily read. This last requirement is the most difficult; even with the clearest of writing it is not easy to make the essential features of a case stand out from a closely written card. When a convoy arrives at a base hospital a rapid survey of all cases has to be made, and it can be very wearying to read through a long description, trying to pick out the salient points. Typewritten notes with bold underlining of all facts of importance are by far the most satisfactory, and a typewriter, if it can be obtained, is invaluable. A point often overlooked is the filling-in in block capitals of the diagnosis on the envelope. In addition to any relevant special labels we also made a practice of printing on this envelope any special instructions for the medical units on the line of evacuation. As examples of this one may mention such headings as "Suprapubic cystotomy," "Watch circulation in foot," "Potential gas gangrene." This ensures that these points will not be missed.

During operations the unit clerk has a table reserved for his use in the theatre. His duties are: (a) To check up the particulars of the patient and discover the time of wounding before the start of the anaesthetic; these are entered in the operating book. (b) To type the operation notes as dictated to him during or after the operation. (c) To write a short précis in pencil in the operation book. It is more convenient to write up all the cases at the end of a list than at the end

of each operation. The space between cases may well be taken up in reviewing the pre-operation ward. It is surprising how easy it is to forget the detail of some of the earlier operations, and these pencil notes are a great help. (d) To search the pockets in any discarded clothing, collect the contents, and see that they leave the theatre with the patient.

#### Extra Equipment and Comforts

In addition to the ordinary scale of active service equipment there are a few extras that make the difference between discomfort and moderate comfort. There are two considerations of importance that are antagonistic to each other. First, the unit must remain mobile and the accommodation on the transport is limited. Any large accumulation of non-essential stores will mean that a corresponding quantity of essentials cannot be carried without overloading the lorries. Secondly, prolonged spells of operating on severe and mutilating wounds are somewhat depressing. The efficiency of the unit will suffer if a few extras are not available to allow recreation, relaxation, and an occasional "brew-up" during quiet times. A personal visit to the N.A.A.F.I. will usually secure sufficient tea, milk, and sugar and other minor comforts. We carry with us a small library for the men, which is changed when possible. Penguin books are a convenient size and can often be exchanged with other units. Gum-boots, a leather jerkin, a small primus stove of the collapsible type, a clasp knife with a strong tin-opener, and a spare roll of toilet paper are all items well worth carrying, if they can be obtained.

It is not claimed that this article contains any profound observations or original points—others who have worked in forward areas may disagree with some of our opinions—but it is an attempt to describe some of the things that we did not know when we started out and which we know now. It has been our good fortune to have a close liaison with the units to which we have been attached and the base hospitals to which our cases have gone. We record with great pleasure our thanks for the help that they have given us and the kindness they have shown us. For reasons of security they must remain anonymous. We also wish to record our thanks to Col. C. Donald, Consulting Surgeon, Eighth Army, for his help with this article.

#### ADDENDUM

*The following explanatory note has been added by the Army Medical Department, War Office.—ED., B.M.J.*

Surgery with a relatively independent mobile team and at a forward centre in the field has always made a strong appeal to the imagination; the views expressed in this article backed up by considerable experience should prove both welcome and valuable at the present time when a considerable number of Army surgeons are posted to Field Surgical Units. It is hoped that this note will assist those who are not conversant with the organization of the forward surgical service in the Army, without detracting from the merits of the article. The lay mind, attracted by the idea of providing expert surgery well forward in the battle zone, is too apt to forget that unless adequate rest and post-operation nursing are also provided the benefits of surgery may be completely lost. Operation is only one stage in the treatment. A proportion of the severely wounded men whom an advanced surgical centre must treat cannot be moved in under seven to ten days without grave risk.

The employment of Field Surgical Units is governed by two definite limitations: (a) The unit is designed for operating only; it cannot hold or nurse patients after operation. Consequently, this one-team unit is not self-supporting in the medical sense, although independently mobile; it carries the necessary surgical equipment—a tented theatre, with bivouacs for the personnel—but possesses neither ward accommodation nor staff for post-operation nursing. It must, therefore, be attached to a unit capable of providing both. (b) Again, there is a limit to the number of wounded the unit can deal with in any one day. Sixteen to twenty serious wounded may be regarded as a capacity load for 24 hours; of these, the last four or five may have to wait 15 to 16 hours for their turn on the table. Delay of this length may well prejudice their chances of recovery. Herein lies the necessity for good triage. The unit must not be permitted to become "cluttered up" with patients who can be evacuated.

### Surgical Centres: their Formation and Siting

The term "surgical centre" implies the existence of facilities not only for major surgery but for holding and nursing patients up to 14 days, if necessary. The Forward Centre for the troops of fighting formations is normally formed by a C.C.S. which can provide all the requisite facilities. It carries two surgical teams. Surgical reinforcement is provided as required by attaching Field Surgical Units. An Advanced Centre is established only when the distance between the evacuating units (Field Ambulances) and the Forward Centre is such that the "time-lag" for the serious wounds is beyond the margin of safety. This Centre is formed by attaching two or more Field Surgical Units, usually with a Field Transfusion Unit, to a Field Dressing Station, light section of a C.C.S., or a static Field Ambulance. It is seldom possible to post Army Nursing Officers (Q.A.I.M.N.S.) to an Advanced Centre, so that the standard of nursing and accommodation is not so high as that at the normal centre. These disadvantages are unavoidable: the additional risks are justified and offset by the urgency of the surgery.

## Correspondence

### Prevalence of Ketosis in Children

SIR.—It is regrettable that following Dr. Evans's excellent description and careful observations in cases of "sick stomachache" (March 25, p. 432) it is the end-results that are stressed and treatment advised to neutralize them, while the causative allergic basis is not realized so that the proper prophylactic treatment can be inaugurated.

During the past fifteen years, in dealing with large numbers of allergic children and adults, I have labelled the various symptoms described by Dr. Evans as "abdominal migraine" to indicate the usual sequel. These symptoms occur extremely commonly in everyday practice, and their allergic origin is totally unrecognized. As in most illnesses of young children abdominal symptoms are most obvious, so in the parent's history they predominate—lack of appetite, abdominal pain, nausea, or vomiting, often accompanied by a sudden high temperature up to 104° F. for a few hours. Perhaps only one of these symptoms will be present in each attack, but sooner or later others appear, and new ones may replace former ones. It is only towards puberty that the children voluntarily describe any headache or eye signs, but will admit such much earlier if specially asked. A well-marked family history of migraine, sick headaches, or other allergic conditions can be elicited usually, as well as other allergic conditions in the individual sufferer.

The attacks may be due to a sensitivity to environmental articles (bedding, pillows) if appearing predominantly in the night or on waking, and to foods if in the day. But later most cases show a combination of both groups of allergic factors, and the apparent exciting cause appears to be some non-allergic factor which lessens or depletes the protective adrenaline production—the nervous or physical exhaustion mentioned by Dr. Evans, or, more correctly, a chemical exhaustion. The primary factor is not so much faulty fat metabolism as that the "fatty" foods are those to which children are most commonly allergic—milk and other dairy products, egg, pig products, chocolate, and fish-oil emulsions. Glucose proves beneficial because it provides immediate essential energy, in itself never producing allergic reactions, and diminishing the "acidosis." A high percentage of cases, and especially those with a poor appetite, show a low curve of free hydrochloric acid on fractional gastric analysis.

The most effective treatment in these cases is to skin-test the child to determine the causative allergen and avoid the cause if possible; medicinally, to give, say, to a child of 7 years, 15 m of dilute hydrochloric acid B.P. in a wine-glassful of water at the beginning of each meal, 1/2 gr. of ephedrine hydrochloride at bedtime, and 3 to 4 tablespoonfuls of glucose a day in drinks. An acute attack can frequently be cut short by a hypodermic injection of 3 to 5 m of adrenaline chloride, 1/1,000 solution, as the intense abdominal pain is

due to a spasm of the smooth muscle of the bowel together with some urticarial oedema of the mucous membrane with the consequent retention of faeces. In severe cases of abdominal migraine it has been my custom to give the mothers a note stating in my view the nature of the case, and asking that the appendix be not removed unless there is very evident proof of its inflammation; since when the incidence of useless appendicectomies in these cases has lessened.

Let us recognize the true basis of cyclical vomiting or sick stomach-aches in childhood and prevent the sick headache or migraine of later life, so that the Home Guards of the next war will not be heavily fined for missing a parade on account of a migraine attack, and the consequent indignation caused among Members of Parliament, where so many bad sufferers seem to be congregated, may be allayed.—I am, etc.,

London, W.1.

GEORGE BRAY.

### First Aid for Burns

SIR.—The letter from Col. Colebrook (March 4) calls for some observations. No clue is given as to the time when Col. Colebrook began this investigation because of "the absence of an agreed policy with regard to the first aid for burns." One had thought that as long ago as 1941 surgeons with wide experience of the treatment of burns and scalds were firmly agreed as to the policy which should be adopted for first-aid treatment—viz., all patients with extensive burns (of more than 5% of body surface), or burns complicated by other injuries or which involve the face, hands, feet, or eyes, should be treated only for shock as a first-aid measure and should receive further treatment at a hospital, to which they should be removed as rapidly as possible. A practical and detailed scheme of first-aid treatment for burns of all types is set out in E.M.S. Memo. No. 7 issued by the Department of Health for Scotland (June, 1941; price 2d.). I am not aware of any knowledge which has since come to hand which does not bear out the principles laid down in this memorandum, apart from the recommendations in it with regard to the use of tannic acid.

It is surprising that the covering of extensive burns with a clean cloth of some kind is not specifically mentioned by Col. Colebrook, in view of the emphasis laid on the danger of contamination by streptococci. It would be interesting to know what is meant by "considerable delay" in the "full-dress treatment" of severe burns. The decision to delay treatment in such cases is a serious responsibility, and such interim treatment as the application of the "Glasgow No. 9 cream" can hardly be called "first aid" under these circumstances. It appears that the potential seriousness of a thermal injury of 10% of the body surface is still imperfectly appreciated. It is not clear on which type of burn the cream may be left for only two days. I should be interested to know whether the extensive clinical trials of the cream included estimation of blood sulphonamide level and tests of liver function.

Finally, one wonders who is to apply the cream as a first-aid dressing. The injunctions regarding the prevention of streptococcal infection are admirable in theory but are evidence of a lack of appreciation of the circumstances under which the cream may be used. Even if the cream is obtainable, such precautions as masking and washing of hands are difficult to observe in the average tenement of a Scottish town, as Col. Colebrook should know from his recent experience in Glasgow, and equally difficult during or after an air raid. Under these circumstances plastering the burn with cream is a waste of time, and must be classed as meddling and valueless.—I am, etc.,

Edinburgh.

A. W. WILKINSON.

\* \* We have sent a copy of the above letter to Col. Colebrook, whose reply follows.—ED., B.M.J.

SIR.—The investigation of first-aid procedures referred to in the *Journal* (March 4, p. 342) was begun in May, 1942. I had not then heard (nor did I until last week) of the pronouncement (June, 1941) by the Department of Health for Scotland to which Mr. Wilkinson refers. Unless that pronouncement includes full bacteriological evidence as to the efficacy of the first-aid measures recommended for warding off infection by haemolytic streptococci I still think there was a good case for

the investigation carried out by my colleagues and myself in Glasgow. Even now I maintain that there is no agreed policy with regard to first-aid treatment.

Mr. Wilkinson will find the details he asks for in the full account of our investigations, to be published in the forthcoming (April) issue of the *British Journal of Industrial Medicine*. I agree that the "covering of extensive burns" with a clean cloth is ideal—but is seldom practicable. I also fully agree with him as to the difficulty of applying first-aid treatment in many circumstances. It cannot be too strongly urged that most burns should simply be covered with something sterile, or at least "socially clean," and sent straight to hospital. Well-meaning "first aid" will often do more harm than good if the circumstances do not allow it to be carried out aseptically.—I am, etc.,

Burns Unit, Birmingham Accident Hospital. LEONARD COLEBROOK.

### Symptoms of Air in the Mediastinum

SIR,—In your issue of Oct. 23, 1943 (p. 533), a question was asked concerning a patient with a supposed "pleuro-pericardial tub." May I suggest that the signs and symptoms in this patient were quite in accord with those found in benign pneumomediastinum. The sudden onset, the severe substernal pain aggravated by exertion, adventitious sounds over the praecordium (due to the beating of the heart and the movement of the lungs against a pleuro-pericardial fold distended with air bubbles), which altered or disappeared with change in posture, the regression of symptoms within a week or ten days, and the recurrence of the condition, are all not only compatible with the diagnosis of air in the mediastinum but might almost be designated as classical features of pneumomediastinum. In the event of a recurrence in this patient or the appearance of similar symptoms in others, an x-ray picture should be taken—not the usual antero-posterior one which obscures the presence of air beneath the sternum, but a lateral one, which will reveal the air.

Pneumomediastinum may occur under a wide variety of conditions which fall for the most part into two main categories: (1) excess physical exertion, such as running, lifting heavy weights, straining in any way; the onset may be a day or more after the exertion or immediately following it. (2) Respiratory infections involving atelectasis in some areas of the lung, which areas may be small, with compensatory over-inflation in others. The infection may be very mild, even unsuspected, or it may be severe. A combination of (1) and (2) may occur.

Pneumomediastinum may be benign and clear up spontaneously with reabsorption of the air; it may be followed by a rupture of the mediastinal pleura with a resultant pneumothorax, or of the fascial planes of the neck with a resultant subcutaneous emphysema. It may be fatal if: (1) the contained air does not escape from the mediastinum and raises the pressure there to the point at which circulation through the heart and great vessels of the thorax is dangerously impeded altogether inhibited; (2) the pneumothorax should prove to be bilateral. (3) if the air in the pleural cavity is under too high a tension. It may be relieved in those cases in which it threatens to be fatal by inserting a hollow needle into the mediastinum at the side of the sternum, or a catheter into the base of the neck and pushing it down to the site of the encapsulated air, thus allowing for its escape. Pneumomediastinum is much more common than is thought, and should be suspected in all such cases as that reported.—I am, etc.,

London, Canada

### Medical Research as a Career

SIR,—The improvement that took place in the organization of medical research between 1919 and 1939 was considerable, but everybody will agree that much more should be done. The most urgent need is for personnel of the required standard. At present the recruitment of men and women is extremely haphazard. Generally it happens that an individual who has

just finished a house appointment feels an urge to investigate some subject while he is waiting for another appointment. The subject chosen is often one that would employ 50 workers for 50 years. With the help of his late chief he gets a grant or scholarship, and at the end of a year writes a report which is useless, and passes on. In a small percentage of cases the researcher is a rather better man and applies for a larger scholarship, and may work very much on his own for a few more years. Unless he is an exceptionally brilliant man he is unable to go further. Many such people fail because they have not been taught how to do research, and, although research workers, like poets, may be born and not made, both require to be taught their A.B.C. It is a truism that research in these days needs a team with a brilliant leader and less brilliant people to help; but under present conditions none but the most brilliant dares to decide on a career of pure research because of the uncertainty of making a living. Even the most brilliant generally have to have a secondary appointment such as teaching in order to make ends meet.

The remedy for these difficulties is to make medical research a profession. The candidate would apply for admission, and if, on general grounds, he was considered suitable he would be sent to a "recognized" institution where a certain piece of work would be assigned to him for a year. If at the end of a year the candidate showed promise, he would be allowed to choose a piece of research that interested him in the same institution or another. At the end of a four-years apprenticeship he would, if considered suitable, be recognized as a member of the research profession. Once admitted to the profession his salary must be assured to him and he must be free to continue his research in whatever direction it leads him, even if this necessitates his being moved to another institution; and if the institution cannot afford his special grade the difference must come from a central fund. Competition, with prospects of financial gain, is necessary in most walks of life including the medical profession, but this does not apply to the born research worker. In the case of the latter it is generally necessary to safeguard him from falling into a financial mess, the worry of which will impede his work.

To summarize, therefore, it seems to me that if better and more research is to be obtained the following are essential: (1) an apprenticeship; (2) an assured income; (3) the absence of any obstruction to the flow of research, even if that flow should take an unexpected turn. I fully realize that these essentials do already exist in some institutions, but the number of such institutions is small.—I am, etc.,

London, W.1.

MALCOLM DONALDSON.

### Returned Prisoners at End of War

SIR,—From my experience of returned prisoners both in this war and the last I offer a few suggestions to remedy the conditions so ably described by Major P. H. Newman in the *Journal* of Jan. 1. The difficulties can be divided into three main groups for treatment in order of importance: (i) psychological, (ii) physiological (gastro-intestinal), (iii) financial.

The immediate desire of all returned prisoners is to see their own families and old localities; this can be provided by sick or privilege leave, but should be limited to a month or six weeks, at the expiration of which reactions set in, so they should report to camps, constructed already all over the country, so that their rehabilitation can start. Their families should be accommodated and accompany them if desired, and live as in married quarters. These camps should be organized by specially selected officers of marked leadership, personality, interested in the object, and endorsed in a superabundance of the "milk of human kindness" and patience. The psychological side should be started and handled by specially trained medical officers, but should not be accentuated or publicized.

The food, its cooking and presentation, should be as individual as possible, but under experienced guidance to reconstitute a delicate and abused digestive system. The organization of the camp should be in the nature of an adventure, and the interest of all be encouraged, the discipline and organization being more on the works' committee idea than the strictness of a Service orderly room.

The financial side is more difficult, but would be worse if the individuals were to compete in the open market, and on

finding their inability to compete with their fellow men would develop a disillusioned, disappointed, aggrieved character at variance with the world. By retaining a man in the Services with his pay and allowances and educating him generally after the A.B.C.A. manner, finding his trade, modernizing him in it by suitable instructors before his release, he will enter the world with a greater confidence in himself and on equal footing as to ability with those more fortunate.

There are two likely factors to upset this Utopia: (i) alcohol, (ii) failure to rouse the initiative, or desire, to work. The first can be overcome by a gradual decrease, either by a system of coupons or by rationing, and making the camp institutes or canteens more attractive, sociable, and comfortable than the outside public-houses. The second is the hardest thing to deal with and will need wiser brains than mine to suggest a method, but it will be a very real state, and there might be a fair number of such cases.—I am, etc.,

C. H. CHAVASSE,  
Major, R.A.M.C.

### First Aid according to St. John's

SIR.—Like many other doctors who teach and examine in first aid, I have been extremely disappointed that there has been no new edition of the St. John first-aid book since 1939. I wonder how many doctors who have themselves to render first aid to a fractured humerus find three little bits of wood and fasten them round the broken bone? or two pieces of wood for a fracture near the elbow-joint? Is not a simple St. John sling sufficient first-aid treatment for a broken collar-bone? Why should we expect to arrest arterial haemorrhage from the palm of the hand by compressing the radial and ulnar arteries when it is known that the interosseous artery continues to supply blood when the two former arteries are compressed? Are all the bandages really necessary which are prescribed for a fractured femur? Why is a bandage tied round the chest for a broken rib? Surely the idea is to immobilize the broken side only, and a bandage, if it is tied tight enough, will immobilize both sides. How can one prevent the onset of poisoning by hypnotics by attempting to keep the patient awake and by slapping his face? How can one hope to use alcohol as an antidote for prussic-acid poisoning when that poison acts in about 20 seconds? Why are "first-aiders" required to treat the bites from rabid dogs when there is no rabies in this country? Why is so much emphasis placed on tourniquets when we know from experience in air raids that a tourniquet is very rarely necessary?

The first-aid examination has to be conducted within very rigid limits, in that the examiner has to ask the candidates specified questions, the candidate being expected to reply on the same lines as are found in the book, and has to repeat all this out-of-date treatment for the benefit of the examiner. Moreover, the lecturers in first aid are frightened to advocate the correct treatment if it conflicts with that in the book, for fear that the ensuing examiner should expect the candidate to reply exactly according to the book. In fact, one is really tempted to ask whether the St. John first-aid book was written when the Knights of St. John of Jerusalem were fighting the Saracens!—I am, etc.,

Colchester.

M. E. LAMPARD.

### Babies in Glass Cages

SIR.—Dr. Clifford Allen underestimates the danger arising out of cross-infections in hospitalized babies. It is an old saying that babies become ill *ex alimentatione* and die *ex infectione*. The prevention of infections is the main aim in the construction of babies' wards. As compared with the paramount importance of infection the problem of "loneliness" is a minor one. The majority of patients in babies' wards are not yet at a sociable age, and those who already show interest in their surroundings find more distraction in the toys, in the work of the nurse and the medical staff than in the sick companions of their room, whom they cannot often even see. Dr. Allen supports his point of view on the authority of Pirquet. Having worked for 21 years at a children's hospital in Vienna may I be allowed to make some remarks with regard to this point. The importance of infections was fully realized

by Escherich and Pirquet in the construction of cubicles for contagious diseases. Ten years ago, when Dr. Allen visited Vienna, Pirquet was dead, and it is my belief that Dr. Allen would have obtained different information if he had had the opportunity of interviewing Pirquet personally. The principle of glass cubicles—for which unfortunately the appalling term "glass cages" has been used by two writers—has been approached in Vienna in the Reichsanstalt für Mutter- und Säuglingsfürsorge. Prof. Parson's plans, according to which the Babies' Block at the Children's Hospital, Birmingham, was constructed, represents a further advance and an improvement on these ideas.—I am, etc.,

Birmingham.

H. S. BAAR.

### Postgraduate Courses for Service Doctors

SIR.—I wish to join in the plea for postgraduate courses for Service medical officers after the war. As individuals, we are fortunate in being members of a profession, but as doctors among doctors we shall occupy, at the end of hostilities, a very humble position technically. There is an opportunity here for the Government, universities, and teaching hospitals to put into practice the good will and concern for our welfare which are so evident in the speeches and publications of their representatives. In addition, it will help the realization of the ideal of "positive health" by convincing the temporary Service medical officer that the effects of belonging to an age group too young to have specialized have not passed unnoticed by the authorities, and, by giving him some assistance in rescuing himself from a life of medical mediocrity, it will enable him to face his civilian task in a manner which will benefit his patients and his fellow men.—I am, etc.,

DAVID G. SMITH, M.B., CH.B.,  
Squadron Leader, R.A.F.

### Treatment of Cerebral Malaria

SIR.—As malaria is being much discussed at the present time the following observation may be of general interest.

I have recently observed four cases of cerebral malaria while medical officer of the Northern District of British Honduras, which is a hyperendemic zone of *P. falciparum*. They were all of the violent manic type, in which it is essential to control the mania before treatment can be adequately given. My experience of such cases is small, and the usual procedure recommended is morphine and/or chloroform to control the mania, which I have tried but found far more satisfactory.

The first case in this group was an adult male Mayan Indian, very violent and quite uncontrollable with my available staff. His temperature was 104° F. and blood smear showed heavy *falciparum* infection. He was obviously very ill. I therefore called upon all my available restraining powers and managed to give him an intravenous injection of sodium-pentothal in the same dosage as for a surgical patient. He immediately passed into a deep comfortable sleep. I then gave 10 gr. quinine bishydrochloride intravenously and 10 m adrenaline subcutaneously. The result was that the patient slept soundly for 8 hours, instead of the expected 1 to 1½ on such a dose. On awakening he was perfectly normal. His temperature dropped, and with a course of quinine 10 gr. i.d.s. and atabrin 0.1 g. t.d.s. for 5 days he had no relapse.

I was very struck with this and gave pentothal immediately to the next case to be admitted, with similar results; this blood smear was negative. I repeated this treatment on two more cases whose blood smears were positive. The last one, a boy of 16 years, did not react so well, but the manic stage passed to a comatose stage which lasted for 3½ days, with slow but eventual recovery; in this case I did repeated lumbar puncture, with intravenous quinine daily for 5 days.

The explanation is probably that there is some dilatation of the cerebral vessels concomitant with a fall in blood pressure brought about by the pentothal, which, with the adrenaline, probably enables the quinine to act more quickly and directly on the parasites. The anaesthetic properties of the sodium pentothal are probably prolonged by the pathologically oedematous state of the brain. Whatever the rationale of this procedure the transformation of the flushed manic to a state of profound and peaceful sleep, followed by a normal

awakening, is an extremely gratifying one to watch. I regret that I cannot quote the cases in detail, but I am not at the moment in contact with their records.—I am, etc.,

J. ANTHONY GILLET,  
Colonial Medical Service, British Honduras.

### Infant Mortality in Scotland

SIR.—Under this heading (March 11, p. 372) Dr. Margaret McGregor advocates the family allowance which was "first sponsored by the Beveridge report." She forgets that it was a feature long before of the Speenhamland system and the old Poor Law, which proved so disastrous both to children and parents that it had to be abruptly discontinued. Dr. Chalmers vehemently denounced the principle as striking at the sanctity of the family, and the report of the 1834 Commission strongly confirmed his charge. Moreover, the policy is implicit in the provision of meals for school-children. Some of us can remember, all of us can refer to the records of, the strenuous debate which raged some sixty-odd years ago on that subject. Many kind people could only see good in the policy; but others, as kind but with more experience and longer vision, as strongly opposed the compulsory provision on the ground that in the end it would be prejudicial to the children; the real remedy was to allow the wages of the parents to continue to increase as they had been doing and as they did do till 1896. That the latter were right seems demonstrated by the much higher survival rate in the later years of childhood and adolescence before 1890 than in this century.

Injudicious kindly legislation can do more harm than deliberate malignity, and the family allowance, seeming so kind, meant so kindly, is really cruel. No one has a right to urge these wild schemes until it is demonstrated that Government expenditure in this century is not responsible for an awful toll of unemployment, only relieved in time of war; for a constant trend to lower wages, again only relieved in wartime; for two formidable rises in phthisis mortality, again only relieved in wartime. That these trends are the reverse of the trend from 1850 to 1895, when Governments first began to assume the role of Providence, should surely make impatient reformers pause before they urge it further on its arrogant course.—I am, etc.,

Sydenham, S.E.24.

B. G. M. BASKETT.

## Obituary

### ALBERT EIDINOW, M.B., B.S.

Dr. Albert Eidinow worked voluntarily in the department of applied physiology at the Medical Research Institute and found evidence that exposure of the skin to ultra-violet rays put up the resistance to staphylococcal infection. At the St. John Clinic and Institute of Physical Medicine he was in charge of the light department and of the pathological laboratory. He was inventive and designed a "daylight" lamp consisting of a long quartz tube giving weak ultra-violet rays, and a number of incandescent lamps hung on each side of this. This lamp gave as near an equivalent to natural sunlight as possible. Flowers and dyes appeared of the same tint under it as under daylight. Such a lamp had its use then in a picture gallery or a milliner's shop. An hour's exposure of the nude body to this lamp gave the same result as a similar exposure to midday summer sun on the seashore. He found this lamp useful in the treatment of psoriasis and cases of lupus in which the local lesion was treated by intense radiation with the Kromayer lamp. He also invented a small ultra-violet lamp which could be introduced into the mouth and used for affections of this and the throat. Members of the theatrical profession gained benefit from this lamp. The general tonic influence of exposure of the skin to ultra-violet rays depended on the production of a slight degree of sunburn erythema followed by desquamation. To keep the skin sensitive he divided the body into four regions, and giving two treatments

a week allowed 14 days to elapse before any one area received another exposure. This saved much time in treatment, for otherwise the exposures would have to become longer and longer owing to thickening of the horny layer and pigmentation. For cases of acute neuritis and fibrositis, swollen painful joints, and traumatic effusions he used what seems to be an ideal method of counter-irritation. Over an area of skin eight inches square above the painful part he gave an intensive dose of ultra-violet rays—enough to produce strong sunburn—and then covered the area with elastoplast bandage. The patient was told on no account to touch this for a fortnight. Infra-red treatment could be given through the bandage. For infra-red treatment he used large incandescent lamps focused by concave metal mirror, recognizing that the red and shorter infra-red rays penetrate the skin deepest. The longer infra-red rays, from sources of dark heat, only warm the surface whence the heat is conducted in, short-wave diathermy being the only means of securing deep heating. He carried out very successfully the treatment of chronic ulcers of the leg, using ultra-violet rays to clean them and elastoplast bandage, telling the patients to walk about, and also when necessary sealing up enlarged veins. Scores of patients were thereby healed of the long-lasting ulcers.

In the pathological laboratory with a skilled assistant he carried out blood examinations, etc., and made autogenous vaccines. These were made not by heating culture fluids but by exposing them in a quartz flask, which was kept rotating between a pair of mercury vapour lamps, whereby a thin layer was exposed to the lethal effect of the rays. He thought this method, which has been used in the U.S.A., gave a better vaccine. Eidinow took an active part in the postgraduate courses given at the St. John Clinic, and was highly appreciated by patients and students. His contribution to rheumatic diseases will be found in the book published by E. Arndel under that title. He wrote many papers for scientific journals.

LEONARD HILL.

### ALFRED ERNEST RUSSELL, M.D., F.R.C.P.

Dr. A. E. Russell, consulting physician to St. Thomas's Hospital and formerly medical referee to the Treasury and to the Civil Service Commission, died at his home at Finchampstead, Berkshire, on March 26.

Born in 1870 the second son of George Russell, he was educated at Roan School, Greenwich, and St. Thomas's Hospital, and graduated M.B. (with gold medal in medicine) in 1894, and B.S. (with gold medal in surgery) in 1895 at the University of London. His early appointments at St. Thomas's were those of house-physician, house-surgeon, demonstrator of physiology, medical registrar, and resident assistant physician; he was also Salters research fellow in pharmacology. He took his M.D. (London) degree in 1897 and the M.R.C.P. in 1900, and was elected F.R.C.P. in 1908. After a few years as assistant physician to the West London Hospital he was appointed to the visiting staff at St. Thomas's, and on his eventual retirement became consulting physician there. In 1909 he was Goulstonian Lecturer before the Royal College of Physicians, his subject being "Disorders of the Cerebral Circulation and their Clinical Manifestations." He examined for the College in materia medica and in medicine, serving for twelve years in all, and was a Councillor in 1928-30; he also examined in medicine for the Society of Apothecaries. Dr. Russell was the author, with the late Sir Percy Sargant, of the book *Emergencies of Medical Practice*, of which the second edition appeared in 1911, and he contributed frequently to the *St. Thomas's Hospital Reports*. During the last war he held a commission in the R.A.M.C.(T.F.) on the *à la suite* staff of the London Territorial Hospital associated with St. Thomas's.

### ALBERT LUCAS, F.R.C.S.

Though he had retired from participation in British Medical Association affairs for many years, the news of the death of Mr. Albert Lucas, formerly of Birmingham, which took place on March 28 at Stratford-on-Avon, will recall to other members a figure at one time prominent in the central west of the Association and a surgeon highly esteemed in the Midlands.

Albert Lucas was born at Bletchley in Buckinghamshire in 1865. He was educated privately, and entered upon the study of medicine at St. Bartholomew's Hospital in 1883, qualifying in 1888, and he obtained the F.R.C.S. in 1891. His early appointments were those of resident medical officer at the Metropolitan Hospital and house-surgeon at Bart's. In 1891 he was appointed resident surgical officer and, two years later, assistant surgeon at the General Hospital, Birmingham. In 1912 he became full surgeon at that hospital, and on his retirement from the active staff in 1925 was elected consulting surgeon. Occasion was then taken to mark his association with the hospital, extending over more than a third of a century, by the presentation of an illuminated address and his portrait in oils. He was also visiting surgeon to the Jaffray Hospital, Erdington, consulting surgeon to the General Hospital, Nuneaton, and to the Birmingham Institution for the Blind, and lecturer in surgery in the dental department of Birmingham University. He was vice-president of the Section of Surgery at the Annual Meeting of the B.M.A. in Liverpool in 1912, and during the last war he had the rank of major, R.A.M.C.(T.), and served the First Southern General Hospital. On his retirement from practice in 1937 many tributes were paid to him in the city where his life work had been done. He was presented by the Lord Mayor with an illuminated address recording in particular his services extending over thirty years as medical adviser to the gas and public works, the water and other departments of the Corporation.

It was in 1909 that Albert Lucas first became a member of the Central Council of the British Medical Association. In 1911 he was honorary general secretary of the Annual Meeting in Birmingham, and to his fine organizing gifts the success of a noteworthy meeting was largely due. He became a representative of his Division in 1913, and so acted at successive Annual Representative Meetings until 1926. In 1922-3 he was president of the Birmingham Branch. His principal services to the Association were rendered on the Journal, Finance, and Central Medical War Committees, where his business ability, firm character, and cool head were of great value, and some years later on the Hospitals Committee. Of the Journal Committee he made an excellent chairman; his business habit of mind was exactly suited to that position during a time of special difficulty. He was chairman of the Journal Committee during the war period, when the *British Medical Journal* had to be carried on with an increasingly depleted staff and, towards the end, with a most inadequate supply of paper of poor quality. Despite all obstacles the *Journal* continued to give to the medical world in general a good account of events and to provide them with reports of the latest advances in military medicine and surgery. The support which the Editor, the late Sir Dawson Williams, received from the then chairman of the Journal Committee was always gratefully remembered and acknowledged. Albert Lucas was one of the least ostentatious of men, content to work behind the scenes for the good of the profession and of the Association of which he was for so many years a loyal member.

Capt. THOMAS MORRIS BEVERIDGE died suddenly on Feb. 12 at Salisbury, Southern Rhodesia. Born at Roseneath, Dunbartonshire, on March 3, 1906, son of the Rev. and Mrs. T. L. Beveridge, his own mother a doctor, he had made up his mind at an early age to follow in her footsteps. He was educated at George Watson's College, Edinburgh, and graduated M.B., Ch.B.Ed. in 1929. After a house-surgery at Barnsley and a short period of work in Glasgow he went out to Livingstonia as a medical missionary. During a spell at home in 1937 he took his D.P.H. Glasgow and then returned to South Africa to work in the City Health Department, Salisbury. He joined the Southern Rhodesian Medical Corps shortly after the outbreak of war. With his generous nature and cheerful disposition he made many friends both at home and abroad. He was very happy in his work and was very proud of his African regiment. He is survived by his wife.

Dr. SIDNEY DUKE TURNER, who died on March 23, will be mourned by a large circle of friends, professional colleagues, and grateful patients. The son of a medical man, he was born at Lewes in 1874. He was educated at Epsom College, passing on to St. Thomas's Hospital, where he qualified as M.R.C.S., L.R.C.P. in 1897, and Durham University. Graduating in 1900 as M.B., B.S. (M.D. in 1902), he went to Purley, and for forty

years bore the major share in a large general practice. He was indefatigable in the care of his patients, and most sympathetic in all his dealings with those in trouble, and was rewarded by winning to a remarkable degree their confidence and real affection. He was a sound and well-qualified general physician, specially successful in the treatment of children, and a most skilful and experienced obstetrician. Turner was a man of robust health and abounding energy, and had numerous interests, both professional and social, apart from the duties of his practice. He joined the B.M.A. in 1901 and served as chairman of the Croydon Division in 1930-1. He was surgeon to the Purley War Memorial Hospital from its establishment as a cottage hospital in 1899, and for many years chairman of its committee of management. He was chairman of the local District Nursing Association and took a keen and practical interest in all matters connected with Epsom College and St. Thomas's. There were few local efforts for the social and religious welfare of Purley of which he was not an active supporter; he was founder-member and past president of the Purley Rotary Club and for thirty years churchwarden of the parish church. He was keen on all outdoor sports, a strong tennis player, and enjoyed nothing so much on his free Saturday afternoons as to watch international or interhospital football, or cricket at the Oval. He was compelled under medical advice to retire from private practice just before the outbreak of war, but retained some of his public activities. Increasing ill-health, however, compelled him to relinquish these one by one, but his interest in them remained keen to the end. In 1901 he married Lilian, daughter of Sir James Wainwright, then treasurer of his old hospital, and he leaves a son, Lieut.-Col. Richard Duke Turner, M.D., M.R.C.P., who is now serving in the R.A.M.C., and four daughters.

We regret to announce the death of the Rev. SAMUEL HANNA, B.A., M.B., minister of Berry Street Presbyterian Church, Belfast, since 1912. Hoping to increase his power for good, and with the consent of his parishioners, he took up the study of medicine and graduated at Queen's University, Belfast, in 1926. He was then able, in combination with his duties as a minister, to carry on general practice. Many of his parishioners also came to him for medical advice, so that he was able in a unique way to minister to every side of his patients' need. He is survived by a son, Dr. William Hanna, who is in practice in the city of Belfast.

We have received the following tributes to Acting Wing Cmdr. D. S. BATEMAN, whose death in a flying accident overseas was recorded in our Services column last week:

J. J. C. writes: Donald Bateman was probably more widely known among R.A.F. personnel than any other Volunteer Reserve officer in the medical branch. This arose partly from the fact that he worked in the R.A.F. Officers' Hospital in 1940 and 1941, but mainly as a result of his sensitive and most attractive personality. He took a deep personal interest in all his patients, an interest which extended beyond their medical condition into the broader aspects of their individual personal problems. In consequence many of his patients became, and remained, close personal friends. The news of his premature death will strike a note of sorrow in the hearts of many R.A.F. personnel widely scattered in all parts of the world. Although Donald Bateman at the outbreak of war was practising paediatrics, he had a wide knowledge of general medicine and an excellent clinical judgment. Apart from professional subjects he had a really remarkable diversity of interests, which embraced music, literature, and art. By his friends he will be remembered as a most delightful companion who could talk and argue on any subject. He wrote with ease and facility and might well have made a reputation as a writer, though his only published book is a biography of Lord Moynihan.

C. P. L. writes: We who worked with Donald Bateman for the short time he was on the honorary staff of St. Mary's Hospital, Manchester, had learned to appreciate his merits as a colleague. He was unassuming but quietly efficient and, as we know from his previous work, of an original turn of mind. He was also unselfish and hard working and was beginning to take a large share in routine work and in teaching. His writing had already been considerable. Undoubtedly, his untimely death has robbed our paediatric world in Manchester of one who would have added much to its strength at home and its prestige externally.

K. N. I. writes: Donald Bateman and I went through Oxford and St. Thomas's together. He had strong leanings towards writing, and in the early days discussed giving up medicine more than once. After being housemen at St. Thomas's together, we were appointed paediatric internes to the Bellevue Hospital, New York City, and it was here that Donald first found his real enthusiasm for medicine. He was very fond of children, and their sufferings awoke in him an urgent interest in their relief; I have often seen him make a late round when he was off duty just to see that they were all comfortable. He had a trick of discussing things with children as though

they were grown-up which made him greatly loved—as my own daughters will readily confirm. Our ways have run together ever since; we were in Vienna together, and up to the war were continually meeting. He went into the R.A.F., I into the R.A.M.C.; fate even sent us abroad in the same convoy. I saw him last in 1942 in Iraq, when we spent a week together. He was still the same Donald and had managed to get himself put in charge—in addition to his usual duties—of a hospital for the children of native troops; his entry into the ward was heralded as ever by demonstrations of delight.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

At a Congregation held on March 11 Daniel Georges Edouard Cordier, formerly Professor of Physiology at the Ecole Nationale Vétérinaire d'Alfort in the University of Paris, received the degree of Master of Arts (*honoris causa*).

The degree of M.Chir. was conferred on A. G. McPherson, and the M.B., B.Chir. on J. S. Pegum, both by proxy.

### UNIVERSITY OF LONDON

Prof. J. M. Mackintosh, M.D.Glas., F.R.C.P.Lond.&Ed., D.P.H., has been appointed as from Oct. 1, 1944, to the University Chair of Public Health tenable at the London School of Hygiene and Tropical Medicine. He was formerly Chief Medical Officer to the Department of Health for Scotland and since 1941 has been Professor of Preventive Medicine in the University of Glasgow.

## The Services

Col. (local Brig.) G. Covell, C.I.E., V.H.S., and Col. W. R. Stewart, C.I.E., V.H.S., I.M.S., have been appointed Honorary Physicians to the King, in succession to Major-Gen. (local Lieut.-Gen.) Sir G. Jolly, K.C.I.E., and Major-Gen. A. C. Monro, C.B., I.M.S. (ret.), respectively.

### CASUALTIES IN THE MEDICAL SERVICES

*Prisoners of war.*—War Subs. Capt. W. H. McDonald and C. B. Meldrum, R.A.M.C.

*Reported missing, believed killed on active service.*—Surg. Lieut.-Cmdr. L. Merrill, R.N.

*Reported killed in action in Burma.*—Capt. J. T. Robinson, R.A.M.C.

*Died.*—Capt. E. M. Gracc, R.A.M.C.

## Medical News

Mr. J. Johnston Abraham will give the Thomas Vicary Lecture on "The Early History of Syphilis" at the Royal College of Surgeons of England on Thursday, April 13, at 4 p.m.

At a meeting of the Eugenics Society on Tuesday, April 18, at 5 p.m. in the rooms of the Royal Society, Burlington House, Piccadilly, W., Mr. D. Caradog Jones will speak on "The Standard of Living." All interested in this subject are invited to attend.

At the sessional meeting of the Royal Sanitary Institute to be held on April 26 at 3.30 p.m., Dr. George F. Buchan, M.O.H. for Willesden, will read a paper on "Social Problems and Health"; on May 23 at 2.30 p.m., Mr. H. J. Manzoni, city engineer and surveyor, Birmingham, will read a paper on "Sanitation in Post-war Building." Every Fellow, Member, and Associate of the Institute may introduce one stranger to the sessional meetings.

A meeting, under the chairmanship of the Lord Mayor of London, will be held in furtherance of Hospitals Day, at the Mansion House on Friday, April 28, at 3.30 p.m., when the speakers will be Lord Luke, chairman of Hospitals Day, and Mr. Henry Willink, Minister of Health.

Sir George Elliston, M.P., has been appointed chairman of the Board of Management of the London School of Hygiene and Tropical Medicine in succession to Sir Holburt Waring.

Dr. Christie McGuire of Dooars, Bengal, has prepared a stencilled note on quinine, primarily written for the use of assistant medical officers in tea-garden practice, but the method of preparing quinine sulphate injections may be useful elsewhere. Copies can be had from the Secretary, Indian Tea Association, Royal Exchange, 2, Clive Street, Calcutta.

## Medical Notes in Parliament

### Penicillin Committee

In the House of Commons on March 22 Sir ANDREW DUNCAN, in reply to Mr. R. Duckworth, who asked about the composition of the *Penicillin Committee* and what were its connexions in the drug trade of each member, said the Sir Henry Dale, President of the Royal Society, had accepted an invitation to be the chairman of the committee. Mr. Arthur Mortimer, deputy director of medical supplies, Ministry of Supply, until recently the chairman, would act as vice-chairman and the other members of the committee were: Dr. V. D. Allison, Ministry of Health; Lieut.-Col. H. J. Bensted, Army Medical Department, War Office; Prof. R. V. Christie, Medical Research Council; Prof. A. Fleming, St. Mary's Hospital; Prof. H. W. Florey, School of Pathology, Oxford; Dr. C. R. Harington, Medical Research Council; Dr. I. M. Heilbron, professor of organic chemistry, Imperial College of Science and Technology, and Scientific Adviser to the Ministry of Production; Prof. R. P. Linstead, deputy director of scientific research, Ministry of Supply; Prof. H. Raistrick, London School of Hygiene; Sir Robert Robinson, Dyson Perrins Laboratory, Oxford; and Sir Russell Wilkinson, military medical adviser, Ministry of Supply; together with representatives of firms engaged in the production of penicillin.

*Army Leave for Examination Purposes.*—On March 28 Mr. LIDDALE asked the Secretary of State for War if a medical officer in the Army with English qualifications must forgo any leave due to him if he wished to sit for Scottish medical examinations. Sir JAMES GRIGG: While a medical officer is not given additional leave, he is allowed to draw on the next period of privilege leave due to him in order to sit for the examination. I need hardly add that these rules apply to all officers, no matter where they have acquired their present qualifications or where they wish to acquire further qualifications.

*Chiropody.*—On March 28 Mr. SILKIN asked the Minister of Health whether chiropody treatment would be included in the proposed comprehensive medical service; and whether he would, in the meetings he was about to hold with interested parties and organizations, include the two national organizations comprising chiropodists. Mr. WILLINK replied that where the help of a chiropodist was needed in providing the full medical treatment for which the new service would be designed, that help must clearly be enlisted. In so far as any special arrangements were required to secure this, he would not hesitate to consult the appropriate organizations.

### Notes in Brief

There are two scales of salary in Nigeria for Government medical officers who are required to have similar minimum professional qualifications: those not domiciled in West Africa and appointed to the *Colonial Medical Service* start at £560 and rise by increments to £1,200; those domiciled in West Africa and appointed locally start at £400 and rise to £720.

At Dec. 31, 1943, the latest date for which figures are available, the numbers of tuberculosis cases awaiting institutional treatment provided by tuberculosis authorities in England and Wales were 529 children and 2,752 adults. Of these 233 children and 189 adults had non-pulmonary disease.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In England and Wales there was a general rise in the incidence of infectious diseases. The increases in notifications over last week's totals were: scarlet fever 180, measles 128, whooping-cough 120, acute pneumonia 106, diphtheria 61, dysentery 61. The incidence of measles has risen for ten consecutive weeks, but the disease is prevalent in only a few counties: 1,159 cases, slightly more than one-half of the total, were notified in the four counties of London, Kent, Essex, and Lancashire. The chief fluctuations during the week were in Lancashire, Essex, Middlesex, and London, where the total of notified cases rose by 146, 106, 61, and 42 respectively, and in Norfolk and Wiltshire, where the total of notified cases dropped respectively by 109 and 46. For the sixth consecutive week the notifications of dysentery have exceeded 200. No fresh centre of infection was reported during the week; the total increase was due to higher notifications in established outbreaks. The largest returns were Lancashire 60 (Manchester C.B. 40), London 37, Middlesex 28, Surrey 21, Essex 18, Derbyshire 12, Yorks West Riding 11.

In Scotland the weekly total for notifications of diphtheria rose by 44, for dysentery by 42, and for measles by 39. The incidence of diphtheria reverted to the level at which it had been almost constant until the fall during the previous week. The only large new outbreak of dysentery was that of Dumfries County 18. The notifications of dysentery in Glasgow and

# TRIOFAX

## *Triple Dye Jelly*

'Triofox' brand Triple Dye Jelly is a stable, water-soluble preparation incorporating the triple-dye formula which has been widely advocated for the treatment of burns, particularly of the face or extremities. It produces a light flexible tan which remains in place until healing is complete. The combined dyes form an effective antiseptic barrier against infection and sepsis. 'Triofox' is useful in

the treatment of skin disorders such as cutaneous ulcers, impetigo, impetiginous dermatitis, seborrhoeic dermatitis and intertrigo.

TUBES OF 2 OZ. AND 4 OZ.

## Origin of a 'household word'

### WRIGHT'S LIQUOR CARBONIS DETERGENS

By the preparation of Liquor Carbonis Detergens 80 years ago, the powerful antiseptic and antipruritic agents in Coal Tar were isolated for the first time from the residuary content of irritants and non-therapeutic substances. Publicly commended by an impressive succession of notable authorities, Liquor Carbonis Detergens soon provided the basis for a toilet soap that has been a household word for generations. Discouraging germs, Wright's Coal Tar Soap produces a generous lather, specially soothing and very thorough in its cleansing.

# \*Wright's COAL TAR SOAP

# STILBOESTROL-BOOTS

## FOR PROSTATIC CARCINOMA

Clinical results have confirmed the value of Stilboestrol in the control of prostatic carcinoma.

Kahle et al (*J. Urol.*, 1942, 48, 83) reported prompt relief of pain and urinary symptoms, the clinical improvement being associated with the regression of the malignant lesion both primarily and metastatic.

Dodds and Walker (*Brit. med. J.*, 1943, 2, 436) observed eight cases of carcinoma of the prostate which were rendered completely symptom-free by Stilboestrol treatment.

# Prescription Feeding of Infants

A great deal is heard just now of standardisation, but nutritional requirements of infants are not susceptible to such regimentation, and exceptions will be found to "prove" almost every rule.

The great majority of infants thrive on COW & GATE FULL CREAM MILK FOOD, but for the remainder "prescription" feeding is available to the doctor in a range of special foods of which the following is a selection:

HALF CREAM

For fat intolerance and cases requiring reduced protein.

HEMOLAC

With supplementary iron in the form of ferri et ammon. cit.

HUMANISED

Approximating to breast milk in balance of fat, protein and carbohydrate.

LACIDAC

Lactic acid food for cases of gastro-intestinal disturbance. In three grades, Separated, Half Cream and Full Cream, to permit graduation of feeding in returning to normality.

FRAILAC

For prematures.

ALLERGILAC

For dermatitis and other allergic manifestations of milk protein sensitivity.

PROLAC

For gastro-enteric cases and others requiring increased protein.

MODILAC

With carbohydrate modification employing dextrin and dextrose.

Full particulars of these and other special foods are available on application to:

COW & GATE LTD.

GUILDFORD, SURREY ©3308

Edinburgh were almost doubled, with a total notification of 1 and 18 cases respectively. The largest rise in the local incidence of measles was in Renfrew C., Greenock B., where the cases rose from 14 to 32.

In *Eire* the total weekly incidence of measles fell by 118 cases. A decrease of 69 was recorded in Dublin C.B.

In *Northern Ireland* the incidence of scarlet fever decreased by one-third, 42 cases. 50 of the total of 85 cases were recorded in Belfast C.B.

#### Smallpox

A mild case of smallpox has been notified in North Dorset, the patient being a woman teacher of one of the Yeovil schools. The source of infection has not been established, but it is understood that the woman visited South Wales a fortnight ago.

#### Week Ending March 25

The notifications of infectious diseases in England and Wales during the week included: acute pneumonia 1,270, scarlet fever 2,389, whooping-cough 2,244, diphtheria 666, measles 2,759, cerebrospinal fever 101, dysentery 274, smallpox 1, paratyphoid 6, typhoid 9.

#### Last Winter's Health

In a review of the winter's health at a Press conference last week Sir Wilson Jameson recalled that in the week ended Nov. 20 there were over 100 deaths from influenza in the great towns. In the weeks ended Dec. 11 and 18 deaths were over 1,100. This wave constituted the only influenza epidemic to occur during the war years, the last comparable epidemic being in the winter of 1936-7. As always with influenza, there had been a great deal of respiratory disease such as bronchitis and pneumonia. These were very prevalent at the tail end of the year, particularly before Christmas. There were a large number of deaths, mainly among old people. As a result the December quarter death rate was the highest for any December quarter since 1918. The corrected infant mortality rate for 1943 had been estimated provisionally at 50; figures for the earlier years were: 1939, 51; 1940, 57; 1941, 60; and 1942, 51.

A big decline in deaths from diphtheria was recorded in 1942. The provisional figures for 1943 will disclose a new low record, being about 30% lower than in 1942. "This is very good," said Sir Wilson. "The fall in deaths is a definite sign that the great effort to get children immunized throughout the country—a move in which the Press has played no little part—is having an effect."

Referring to the recent outbreak of smallpox in the vicinity of London, Sir Wilson said that, so far as could be judged, no further cases were likely to arise. Activities at the hospital concerned were again normal. He stressed that the amount of work involved even in a small outbreak of this kind was "almost unbelievable." There were eleven cases, but they necessitated a most detailed inquiry into about 3,000 contacts. The movements of each of these 3,000 people had to be checked. Medical officers of health all over the country had to be notified of contacts in their areas. Each person concerned was offered vaccination or re-vaccination. Library books used by contacts had to be traced and if necessary destroyed; articles of laundry had to be recovered; there was a search for a barber who had shaved contacts and cut their hair.

#### Medical Relief in Europe

An outline of the medical aspects of post-war relief in Europe was given by Dr. Melville Mackenzie, one of the Ministry's medical officers, who was chairman of the Medical Advisory Committee of the Inter-Allied Committee for Post-war Requirements. He said that so far as medicine was concerned it was possible to forecast fairly accurately the problems that were likely to arise during the post-war period as the countries of Europe were liberated. In the aftermath of the last war more people died from preventable diseases and starvation than were killed in the war itself. The first problem to be faced was that of malnutrition. Until a reasonable standard of nutrition was achieved it would be very difficult to do effective medical relief work. The second big medical problem would be the re-establishment of medical services. It would also be necessary to convey to the doctors, professors, and medical students of European countries details of the great advances made in medicine during the five years of war. Among these advances were the use of the sulphonamide drugs, penicillin, and mass radiography; work in connexion with typhus control, etc. Epidemics which were most to be feared so far as Europe was concerned were those of typhus fever—which killed about 5,000,000 people at the end of the last war—and malaria. Before the war there was a very effective system of notifying major epidemic disease from every country in the world. This information covered about 90% of the world's population. The reconstitution of this inter-Government information service would be one of the most urgent pieces of post-war work.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 18.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (1) London (administrative county) (c) Scotland. (d) *Eire*. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 13 principal towns in *Eire*. (d) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes no return available.

Disease	1944					1943 (Corresponding Week)

\* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and *Eire*.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

## Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1.

ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Members' subscriptions should be sent to the Secretary of the Association.

TELEPHONE No.—B.M.A. and B.M.J.: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Attilology Westcent*, London: SECRETARY, *Medisecra Westcent*, London. ADVERTISEMENTS, *Articulate Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh.

### ANY QUESTIONS?

#### Achlorhydria

**Q.**—What diet do you recommend for achlorhydria? The patient is unable to tolerate hydrochloric acid.

**A.**—Achlorhydria in itself requires no treatment. It is present without symptoms in a large proportion of the population, particularly in the later age groups. If achlorhydria is found in the investigation of a case of dyspepsia it is unlikely that the symptoms are due to lack of HCl or pepsin. The achlorhydria may well be a pure coincidence. On the other hand, achlorhydria may be associated with an active gastritis, and treatment should be directed to that. In pernicious anaemia the dyspepsia is usually relieved by liver treatment, and if it persists cholecystitis or gall-stones should be suspected. The association of achlorhydria with carcinoma of the stomach should be borne in mind. If a diagnosis of achlorhydric gastritis is made, the diet should be adequate in all essentials, digestible, and mechanically non-irritating. Meals should be small and rather dry and intermediate feeds may be taken. In fact, the ordinary Sippy diet for gastric ulcer will serve well with very slight modification. The main difference is that gastric stimulants such as meat extracts, soup, beef tea, marmite, etc., are to be encouraged. Fruit juices are also favoured by some dietitians. As achlorhydria occurs in vitamin-B deficiency it may be well to pay special attention to foods rich in vitamin B, such as liver, oatmeal, beans and peas, and wholemeal bread. So long as the food is properly cooked and served there is no reason why any of these should produce dyspepsia. The main use of hydrochloric acid is in the treatment of diarrhoea associated with achlorhydria, and, if it is not well tolerated, betaine hydrochloride can be tried in a dosage of  $7\frac{1}{2}$  to 15 gr. in water after meals.

#### Life of Ova and Spermatozoa

**Q.**—Taking the menstrual cycle as starting from the termination of the last period, and presuming the latter to last 5 days, when is the day of ovulation in (a) a regular cycle of 28 days, and (b) an irregular cycle? What is the duration of life of mobile spermatozoa (a) deposited in the vaginal tract, (b) which find their way to the uterus or Fallopian tubes? What is the duration of life of the ovum?

**A.**—Permanent loss of motility is assumed to indicate death of spermatozoa, and, although this may not be true, it is a useful practical criterion. But long before it ceases to be motile a spermatozoon loses its power to fertilize an ovum, and it is presumably the duration of this characteristic which is in question. This is obviously difficult to determine, especially in the human species, and an unequivocal statement is not possible, particularly as spermatozoa

obviously vary in their inherent viability and the conditions in the female genital tract are not constant (e.g., pH). In the human being sperms retain their motility in the vagina for  $1\frac{1}{2}$  to 3 hours only, usually not longer than 2 hours. Their ability to fertilize is lost in a shorter time, and, according to some authorities, within a few minutes. In the cervical canal, uterine cavity, and Fallopian tubes motility is preserved for 4 to 5 days or slightly longer; former statements of 21 days are no longer accepted. Again the power to fertilize is retained for a shorter period; the exact time is unknown, but it is probably about 24 hours or, at the most, 48 hours.

The life of the ovum is also short, and after 24 hours (possibly less) it is no longer capable of being fertilized. Ovulation occurs more constantly in relation to the next period than to the last, and usually  $14 \pm 1$  days before the onset of menstruation. For a regular cycle of 28 days this means  $14 \pm 1$  days from the onset of the last period—the count should not be made from the last day of menstruation. When the cycle is so irregular that the onset of the next period cannot be predicted, the time of ovulation cannot be calculated.

#### High Birth Weights

**Q.**—What is the greatest known live birth weight? I (Gold Cow, W. Africa) have just delivered triplets of 4 lb. 10 oz., 6 lb., and 6 lb. 4 oz., total 16 lb. 14 oz. All were males, monoovular twins and tertium quid. The singleton was the smallest, and his placenta showed an organized clot with M.T. malarial parasites in a smear.

**A.**—A single foetus weighing more than 11 lb. is very rare. Abnormally large babies are often borne by abnormally large women. Statistics concerning large babies do not always distinguish between live and still-births. Williams says that of 25,000 babies born under his supervision the heaviest weighed 14½ lb. Moss (*British Medical Journal*, 1922, 2, 643) recorded the delivery of a foetus (stillborn after difficult forceps extraction weighing no less than 24 lb. 2 oz.). This foetus was later shown at the Royal Society of Medicine, and reweighing (after a long period in fixative) recorded more than 23 lb. The combined weight of twins or triplets is often relatively high. The composite weight of the famous Dionne quintuplets five days after birth was 11½ lb. I have knowledge of one case of twins in which the babies weighed 8 lb. 1½ oz. and 7 lb. 3½ oz. respectively (total weight 15 lb. 5 oz.). These children were born alive and survived.

#### Coronary Thrombosis

**Q.**—Lately I have had to deal with an unusual number of cases of coronary thrombosis. What immediate treatment is likely to save life? Why do nitrites give relief in cases of angina pectoris and not in cases of coronary thrombosis in view of the fact that in both conditions lesions of the coronary arteries are frequently present post mortem?

**A.**—Nothing is so important in the immediate treatment of a patient with coronary thrombosis as complete immobilization. If up and not too ill to move, he should go to bed and not get out of it. Morphine subcutaneously gr. 1/4 should be given at once, and repeated in 15 to 30 minutes if required and still again, rather than allow the pain to continue. He should avoid unnecessary arm movements, especially stretching out, and he should not shave, or wash himself. This implies efficient but not too active nursing. The giving of an enema is taking an unnecessary risk. Glucose drinks are suitable. Oxygen should be given by nasal catheter or by spectacle frame if there is cyanosis. Digitalis is contraindicated unless symptoms or signs of cardiac failure appear.

Nitrites relieve angina of effort by dilating the coronary vessels. This action cannot relieve the pain from a thrombosed coronary artery with its consequent infarct. Besides, the general effect of nitrites in lowering blood pressure is a reason against their use in coronary thrombosis, which itself produces a significant fall.

#### Disposal of Foetus

**Q.**—There is often some doubt as to the correct disposal of the foetus in cases of abortion, miscarriage, and premature confinement. What should be the correct advice in the following circumstances: (1) up to 3 months; (2) from 3 to 6 months; (3) from 6 to 7 months where the foetus may show signs of life though not viable; (4) from 7 months to term, where the child (a) is stillborn, (b) lives for a short time but is not christened; (c) ditto, but is christened (in this case should the parents arrange for a burial service in church?)? Arising from this last, at what stage of development should the parents be advised to arrange for the baptism of a child which may show signs of life but is obviously non-viable? Lastly, at what stage of development should the foetus be registered as a stillbirth?

**A.**—The time divisions of the question are not significant. To deal first with stillbirth. A stillborn child is "any child which has issued forth from its mother after the 28th week of pregnancy, and which did not at any time after being completely expelled from its mother breathe or show any other sign of life" (Births and Deaths Registration Act, 1926). The medical practitioner or certified midwife in attendance should issue a certificate of stillbirth to the father or other person entitled to register the birth, but he may only do so if he was present at the birth or if, after examination of the body, he is satisfied that the child was stillborn. He may obtain the forms free from the registrar of the district.

If the period of gestation was less than 23 weeks the stillbirth need not be registered or notified; the practitioner is merely required to give a certificate stating that the child was stillborn. A still-born child may not be buried in any burial ground without a registrar's certificate or a coroner's order.

For the remainder, the crucial question both at law and in religion is whether the child ever had a separate existence—that is, gave signs of life after being completely free from the mother. If it did so, then both its birth and its death must be registered and the medical practitioner in attendance must give a certificate of cause of death; to dispose of the body without doing so is an offence under the 1926 Act. The law does not inquire whether a child has been baptized or not. The practice of both the Roman Catholic Church and the Church of England is to baptize a child that shows

gns of life even if it is not viable. In Roman practice the baptism is conditional. In both communities it may be performed in case of emergency by any adult lay communicant. If a child has been baptized, it is doubtless the parents' moral duty to see that it is baptized with the rites of the Church. If the child has shown signs of life within the first 28 weeks of pregnancy, it has had no existence at law and may be disposed of in any convenient way. If the medical practitioner is in doubt whether the foetus may be acquired as evidence in a criminal investigation, he should arrange for its preservation until the police have consented to its removal.

#### Urethral Discharge

**Q.**—What might be the cause of a clear urethral discharge in a young married male? Repeated smear tests and blood tests have been negative for gonococci, and the history is not relevant. May *Trichomonas vaginalis* be the underlying cause? What is the treatment?

**A.**—1. Assuming that not only are gonococci absent but pus cells and other pathogenic organisms as well, a clear urethral discharge may be due to a variety of causes, most of which are relatively unimportant. The discharge may consist of mucus or prostatic secretion and may be indicative merely of excessive secretion from the glands lining the urethra or of prostatorrhoea.

2. It is possible but not probable that *Trichomonas vaginalis* is the cause; this can be decided by examination of a fresh specimen with a dark-ground microscope; in any case *Trichomonas vaginalis* is uncommon in the male and still more rarely causes signs and symptoms.

3. The treatment of *Trichomonas vaginalis* infestation consists in rendering the urine strongly alkaline—e.g., by means of large doses of sodium bicarbonate. The organism cannot persist in an alkaline medium. Should all pathological examinations be negative, it is suggested that a trial be given to a simple alkaline diuretic mixture.

4. On the other hand the discharge may indicate an uncurd gonorrhoea or non-gonococcal urethritis; these can be excluded only by careful clinical examination, including urethroscopy and examination of the expressed secretion of Cowper's glands and prostatic and seminal vesicles.

Should examination of the patient reveal anything pathological, examination of the wife is indicated.

#### Sycosis Barbae

**Q.**—I should be grateful for your views on the treatment of sycosis.

**A.**—If by sycosis is meant a deep staphylococcal infection of the hair (beard and/or moustache), then treatment relies on the mechanical removal of the infected (and other) hairs by forceps, or by x-ray depilation under expert supervision. Local antiseptics are mostly without value because they cannot penetrate and reach the deeply placed focus. An exception to this is found in the benzoyl peroxide and clinolol compound ointment, which should be well rubbed in night and morning. It will be interesting to know if penicillin proves effective.

#### Pediculosis Pubis

**Q.**—Is there any method of treating pediculosis pubis without shaving or the use of irritating substances?

**A.**—The following procedure advocated by H. W. Barber satisfies all the requirements. A pad of lint soaked in 1/40 solution of carbolic acid is applied for one hour. This removes and kills parasites and ova. As a precaution a weak ammoniated mercury ointment is thereafter applied for a few days in case some ova have escaped destruction.

## INCOME TAX

#### Purchase of Practice

"J. L." has taken over the practice of a deceased practitioner. Should his assessment be based on the first year of his "new" practice or on his earnings in the last year of his previous practice?

\* The former—i.e., the practice is treated as "new" as from the date of purchase.

#### Prisoner of War

"A. E." was a prisoner of war from June, 1942, until June, 1943. He received a portion of his pay in Italy (in lire), plus a further payment representing the pay of an Italian officer of similar rank in view of work done as a medical officer. The cost of living in Italy was extremely high, but had to be incurred to ensure ability to perform the work. A claim has been made to deduct a part of such expenses as being incurred "wholly, necessarily, and exclusively in pursuit of the employment," but the claim has been rejected.

\* The Courts have maintained a rigid attitude towards claims to regard ordinary living expenses as providing a foundation for an income-tax allowance. Costs of living differ as between different

parts of the United Kingdom, and a salary paid for service abroad—if assessable at all—is assessable in full, notwithstanding high local costs of living. We cannot advise our correspondent to appeal against the decision.

#### Assistant: Commencement of Liability

"C. F." started professional work in Nov., 1942. He has been assessed simultaneously for the five months to April, 1943, and for the year to April, 1944. Deductions of tax started in Nov., 1943. Is this correct?

\* Yes. The preceding year basis does not apply to the first year's earnings, whether those earnings result from employment or otherwise.

#### Assistant Paid Weekly

"C. J." is an assistant in general practice paid weekly.

\* He will come under the new "pay-as-you-earn" system as regards payments made to him after April 5, 1944. As he is not a manual wage-earner the "discharge" of the tax assessable for 1943-4 will be on the basis of 7/12ths and not 10/12ths.

#### Cash Basis: Partner in the Forces

"B. H."—The terms of the partnership deed provide for the bringing into the profits of the practice the Services pay and allowances of a partner serving in the Forces. The inspector of taxes insists on treating this income as assessable separately under Schedule E, and declines to include it as part of the profits assessable under Schedule D on the firm.

\* The arrangement under which the earnings derived from appointments, etc., are included in the Schedule D assessment is ultra-legal, and rests on a concession of long standing. The Inland Revenue authorities, however, have not so far as we know extended it to cover the case of a partner's Service pay, and we do not think that the concession is likely to be extended in that way.

#### Employment after Demobilization

"R. R." was invalided out of the Forces in Oct., 1943. He did eight weeks' locum work and joined the E.M.S. in Jan., 1944. His earnings in 1943-4 will amount to £467 10s., and he pays £84 in life assurance premiums.

\* He can claim medical subscriptions and car expenses, etc., while on locum work, and may be entitled to a proportion of the uniform allowance for the period in the Forces. The tax chargeable for 1943-4 is apparently in the region of £45.

#### Sale of Practice

"J. M." sold the "goodwill only" of his practice. The inspector of taxes wants to know how much he received for the sale of the practice. Is he entitled to demand this information?

\* No. In any case the inspector has no statutory authority to ask such questions, but does so by long-standing practice to avoid passing the matter on to the District Commissioners (who are entitled to call for evidence) to settle an appeal. This question is apparently directed to ascertaining whether the price received for the goodwill is consistent with the returns made in past years—at least no other reason for it occurs to us—and though there may be no special reason for refusing the information our correspondent is entitled to do so unless and until required by the Commissioners to supply it.

#### Car Temporarily Laid up

"D. H." normally keeps a car for professional work, but in present conditions has laid it up in a rented garage and uses a motor-cycle. The inspector of taxes has refused to allow the cost of insuring and garaging the car because it is unlicensed.

\* In our opinion the inspector's attitude is wrong and would not be supported by the authorities. We advise "D. H." to put the facts in writing to the Chief Inspector of Taxes, Somerset House, London, W.C.2.

#### "Pay as you Earn": Locumtenent

"C. H." asks whether under the new arrangements he will have to deduct tax on paying a locumtenent.

\* We think it must be admitted that in strict law a locumtenent is receiving emoluments assessable under Schedule E, and that legally therefore the new arrangements apply. But the position of a locumtenent is peculiar in that it involves such frequent changes of "employer," and in the past that has been recognized by the authorities and the inconvenience which would result from applying a deduction system in such circumstances has been avoided by regarding locumtenents as within Schedule D and dealing with them accordingly. We do not know, but assume that the same course will be followed under the new arrangements. A practitioner employing a locumtenent would be well advised to consult his inspector of taxes on the point.

## LETTERS, NOTES, ETC.

## Mastoiditis

Mr. G. GORDON MOWAT, F.R.C.S.Ed. (Bolton) writes: I have no doubt that Dr. H. Hilton Brown (March 18, p. 412) writes in good faith, but I cannot allow to go unchallenged his statement that "mastoiditis is not present in the vast majority of cases operated upon." During the present war I have examined many hundreds of cases referred to me on account of chronic discharge from the ears. Most of these are debarred from military service. I think any otologist will agree with me that if these cases had been properly operated upon within six weeks of the discharge commencing they would to-day have a healed drum and normal hearing. Almost any case of mastoiditis will subside without operative treatment, but, nevertheless, infection of the mastoid is present, and the ears continue to discharge.

## Polished Rice and Beriberi

Dr. J. LEASK (Ferndown, Dorset) writes: One hears daily of the sufferings from beriberi of our prisoners of war in Japanese hands. I wonder if they could be advised, say, through the medium of the Red Cross, to expose their rice to the sun for a day before cooking. About 40 years ago, when I was in medical charge of H.M. Prison, Singapore, beriberi was rife among the inmates. They were having polished rice in the diet. With the idea of giving them sea air and removal from a possible source of infection a batch of prisoners were transferred to an island in the harbour, where they received precisely similar food to that given in the prison and from the same source. The result was remarkable; no fresh cases occurred on the island and all improved in health. The only difference was that their rice was spread out on mats and exposed to the sun during the day before being cooked. The rice thus irradiated seems to have regained some of its vitamins, for in the light of subsequent discoveries the marked improvement in the cases on the island must have been mainly due to the irradiated rice. Unfortunately all my papers were destroyed by enemy action, so I am unable to give figures, dates, or other details, having to rely on memory only.

## A New Test for Acetone

Mr. JOHN INGRAM, F.I.C., biochemist to the Medical Unit, Welsh National School of Medicine, Cardiff, writes: Rothera's test is a satisfactory one for ketosis. It is essential to perform this test in a room that is not used for blood and water analysis, otherwise contamination of the reagents will occur and inaccuracies will result. The new test for acetone bodies is carried out on a dry stable powder, containing sodium carbonate, ammonium sulphate, and sodium nitroprusside. The powder detects the presence or absence of acetone in the urine. The colour reaction is identical to that found in Rothera's test, a delicate permanganate tinge develops, which gradually deepens within two minutes if acetone is present. There are no fallacies and the powder will detect acetone in a dilution, 1 part in 10,000 parts of urine. Reagents are prepared thus: 3 g. of sodium nitroprusside is ground to a powder in a mortar, add 100 g. ammonium sulphate and 50 g. of sodium carbonate anhydrous, mix well in the mortar; keep in a dry wide-mouthed bottle. *Method as Applied to Urine.*—Place a small amount of the powder in a dry test-tube (about half an inch). Saturate the powder with a small amount of urine. If acetone is present, the powder will develop a faint permanganate colour to a deep permanganate colour for larger amounts within two minutes. A brown colour does not constitute a positive reaction. By the use of this powder in clinical laboratory practice the performance of the test is simplicity itself and the cost is almost negligible. The test so performed is thoroughly reliable and very sensitive. It does away with objectionable ammonia.

## Quinine Sulphate for Intramuscular Injections

Drs CHRISTIE MCGUIRE, M. L. CHAKRAVARTY, and G. C. KARMAKAR write from Dooars, Bengal: Owing to the shortage of quinine bihydrochloride we have been using quinine sulphate for intramuscular injections, and our results have been so satisfactory that we desire to bring it to the notice of your readers. During the past 12 months we have given about 6,000 injections and to date we have not had any abscess formation. Some of our patients include infants a month old. We have found that the local tenderness at the site of the injection, which is usually given in the buttocks, and the therapeutic results are similar in all respects to quinine bihydrochloride. Our method of preparation is as follows: (1) Add 100 minims of dilute hydrochloric acid to 10 c.c.m. of distilled water and dissolve 100 grains of quinine sulphate in the solution. Then add enough distilled water to make the total quantity 20 c.c.m. (2) Filter through filter paper. To prevent the solution from being absorbed into the paper first moisten the paper with distilled water. After filtering boil and keep in a sterile stoppered bottle. The solution is now ready for use. Each 1 c.c.m. contains 5 grains of quinine sulphate and the usual adult dose is

2 c.c.m. If the solution is not all used the same day and there is any doubt about sterility, the remaining quantity can be boiled again before use. In our experience the efficacy of the quinine is not affected by double boiling. (3) Don't use dilute sulphuric acid for dissolving the quinine sulphate as we have found that after while the quinine crystallizes to the bottom, but this does not occur with dilute hydrochloric acid.

## Treatment of Pregnancy Vomiting

Dr. W. EDWARDS (Ashted) writes: The vomiting of pregnancy seemed to me so similar to the vomiting induced in some people by synthetic oestrogens that I wondered if the large volume of oestrogens present in the blood in pregnancy might be responsible for the sickness in susceptible women. Whether or not that is so I have now treated a dozen cases of vomiting, severe enough to make life a misery, by giving a synthetic progesterone in the hope that it might balance things up. I have used "ethisterone" (Boots), one tablet of 10 mg. daily; and every one of these dozen cases cleared up completely in a week and in none did the vomiting recur. It may have been suggestion, or luck, but it would be interesting to know if anyone can confirm these results.

## Pin-hole Urinary Meatus

Dr. HENRY A. LAVELLE (Derby) writes: In your issue of Feb. 26 (p. 314) there is a question under the heading "Pin-hole Urinary Meatus." The condition described in the question is not due to the embryological cause given in the answer. It might be as well if the facts were stated. Some children pass a urine which soon becomes very ammoniacal. This gives rise to a napkin rash with blisters which ulcerate in bad cases. If this type of child is circumcised the meatus, protected up to now, frequently becomes the site of a more or less chronic ulcer. This, by scarring, causes the narrowing. Enuresis, with more prolonged contact with the urine, obviously is a contributory cause when present. Enuresis may also be due in some cases to the ulceration, as the child, when awake, avoids micturition, as it hurts. This pin-hole urinary meatus is the one important bad effect of circumcision. The treatment is to treat the cause, with a meatotomy later if necessary. Prevention is better than cure.

## Hyperidrosis: Pruritus

Dr. N. S. FINZI writes: Two of the answers in "Any Questions?" are at variance with radiological experience: (1) *Excessive sweating.*—These cases do extremely well with correct x-ray treatment, and I have had no trouble at all, or any failures so far, though some of my cases I have seen more than twenty years after the treatment. I have, however, seen a case of gross damage, but it was not treated by a radiotherapist. A single treatment is usually sufficient. (2) *Pruritus ani et vulvae.*—X-ray treatment in small doses (about 60 r. a week) will very often completely relieve these patients, though it occasionally fails, especially in the type associated with leucoplakia. Underlying causes must of course be eliminated.

## Salt Drink for Cramp

Dr. H. A. DIRCKZE (Wellawatte, Ceylon) writes: I was interested to read two notes on a remedy for cramp on page 402 of the *Journal* of March 27. As a public health officer I have for many years been in charge of ante-natal clinics. A frequent complaint by expectant mothers is that they suffer from nocturnal cramp, especially of the calf muscles. I advise them to drink a glass of water in which half a teaspoonful of common salt is dissolved. One such glass is drunk just before retiring and one is ready by the bed should the cramp come on in spite of the glass already drunk. It has invariably been successful. On one occasion at a tennis tournament a friend of mine who was in the running for the finals developed cramp during a set. He was quite disappointed as he knew from past experience that he would not be able to resume play. I hastily obtained some common salt and dissolved half a teaspoonful in a glass of sweetened lime juice and made him drink it. In a few minutes the cramp disappeared. I gave him another glass of the mixture and he was able to resume his game without recurrence of the cramp. I should mention that the idea came to me because during the D.P.H. course at the London School of Hygiene we were told that the "bends" or severe cramps suffered by stokers on board ship have now been entirely eliminated by giving them normal saline to drink instead of plain water. It was stated that the loss of salt during sweating for some unknown reason (perhaps not known to me only!) causes cramps in some subjects. I, too, had cured myself in a minute or so of an attack of nocturnal cramp by hastily preparing and quaffing a glass of (more or less) normal saline.

## An Answer Corrected

The contributor regrets that his reply to the question on congenital deafness (April 1, p. 481, under the "Any Questions?" section) contains a serious error. The patient is certainly a carrier. This, however, does not affect the opinion given as to marriage.

### A REVIEW OF THE WORK OF A PENICILLIN THERAPEUTIC RESEARCH UNIT

BY

RONALD V. CHRISTIE, M.D., D.Sc., F.R.C.P.  
Professor of Medicine

AND

L. P. GARROD, M.D., F.R.C.P.  
Professor of Bacteriology, St. Bartholomew's Hospital

It is now common knowledge that the discovery of penicillin by Fleming (1929) and its extraction in more concentrated form by Chain and Florey were followed by clinical trials in Oxford by Florey and his collaborators, from which it became clear that penicillin is a therapeutic agent of a new type and extraordinary powers (Chain *et al.*, 1940; Abraham *et al.*, 1941; Florey and Florey, 1943). When further, although very limited, supplies of penicillin became available from commercial sources the Medical Research Council was entrusted with its distribution for extended therapeutic study. The Council's Penicillin Clinical Trials Committee, established in March, 1943, allocated supplies to four main centres, as well as to a number of other institutions where smaller quantities were used for specific purposes. This and succeeding papers constitute a report from one of these centres on work which has now been in progress for rather less than a year.

At this stage the foundations of penicillin therapeutics had already been well laid by the Oxford workers, and the following is a short summary of what was known of its properties. Penicillin itself is highly unstable, but its calcium and sodium salts are relatively stable, and it is in one of these forms that the substance is used therapeutically. All preparations hitherto available have been impure, containing often only a small percentage of true penicillin: dosage is therefore not calculated by weight, but in terms of Oxford units, this being a measure of bacteriostatic power assessed by comparison with a standard product.

Penicillin has three fundamental properties on which its action in the body depends. The first is enormous antiseptic power: even when diluted a millionfold or more it will still completely prevent the growth of certain bacteria. The second is almost complete indifference to the medium in which it acts: other antiseptics with comparable activity in water or broth lose most of this activity when brought into contact with the protein and cellular constituents of body fluids, but penicillin acts as well in serum, blood, or even pus as in broth. Thirdly, it is almost completely non-toxic to the body as a whole, and, so far as is known, to any of its constituent cells: only enormous concentrations, far in excess of those required for action on bacteria, interfere with the activity of leucocytes or any other cells

hitherto studied from this standpoint. These are of course the three properties which have long been postulated, without any serious expectation of ever finding them combined to this degree in one substance, as those of the ideal antiseptic.

It is of the first importance to recognize that this action is exerted only against certain bacteria; others are highly resistant to it, and penicillin has for years been used by Fleming (1932) as a constituent of selective culture media. Susceptible bacteria are almost all Gram-positive, the chief exceptions to this rule being the gonococcus and meningococcus. The most important of the susceptible Gram-positive species are the three main pyogenic Gram-positive cocci—*Staphylococcus aureus*, *Streptococcus pyogenes*, and *Pneumococcus*—and it is noteworthy that whereas staphylococcal infections are far more resistant than haemolytic streptococcal infections to sulphonamides, they are almost equally susceptible to penicillin treatment. The gangrene group (including *Cl. oedematis*, which is relatively sulphonamide-resistant), *B. anthracis*, *C. diphtheriae*, some strains of *Strep. viridans*, and *Actinomyces* have also been found susceptible *in vitro*. More or less resistant species include almost all Gram-negative bacilli—the typhoid-dysentery group and coliforms generally, *Proteus*, *Ps. pyocyanea*, the genera *Haemophilus* and *Brucella*, and *Strep. faecalis* and *Mycobacterium tuberculosis*.

#### Systemic or Local Treatment

Penicillin injected intravenously or intramuscularly circulates in the blood and thus reaches every part of the body, but, owing to the rapidity of renal excretion, heavy dosage is necessary to maintain an adequate concentration. This method of administration is obviously necessary in septicaemia, and has been found so in some local but extensive or inaccessible infections. The dose required for an adult is about 120,000 units daily, and treatment may have to be continued for a week or longer. Thus a million units or more may be given to a single case, whereas a second method of use—the application of penicillin in some form locally to the lesion—may be fully successful and employ only a few thousand units. Owing to the present imperative need for economy, it is therefore a major rule of penicillin treatment to use local application whenever this will suffice. The technique of local application has much to do with success: many new methods have been devised, and further improvements may yet be achieved.

#### The Choice of Cases for Treatment

The impulse of anyone with penicillin at his disposal for the first time is to use it for treating those conditions in which it most clearly excels every other remedy, and particularly for saving life. *Staphylococcal* septicaemia, and septicaemia or meningitis due to a sulphonamide-resistant *Strep. pyogenes* or pneumococcus, are probably the foremost conditions in which penicillin may alone be capable of saving life, and these were among the subjects of therapeutic study approved by the Penicillin Clinical Trials Committee at its first meeting. It soon became evident that the supplies available were quite inadequate

for treating all such cases referred to us, and it has now been decided that cases of staphylococcal septicaemia will not be accepted for treatment. It is one thing to use penicillin to the best advantage in accordance with existing knowledge, and quite another to use it in order to expand that knowledge. The second of these objects was clearly the purpose of our work, and cases are therefore being accepted only if they appear likely to further it. Even were one to resolve to use a limited stock of penicillin for purposes of well-ascertained value, the choice of cases involves decisions of the most difficult kind. As Florey and Williams (1944) have recently shown, 500,000 units of penicillin suffice for the local treatment of over 100 cases of infections of the hand, with an immense gain in rapid restoration of function. The same quantity would cure five cases of sulphonamide-resistant gonorrhoea, and the demand for this purpose may be insistent if the patients are key Service personnel needed in a forthcoming offensive. (Report to War Office, 1943). On the other hand, this quantity of penicillin would be inadequate for the treatment of a single case of septicaemia.

The policy at this centre, although defined only after our work had been in progress for some time, is at present to explore further the possibilities of local treatment in as many directions as possible, and to confine systemic treatment, as a general rule, to early cases of infection of bone—a difficult field in which further study seems desirable. This policy may be changed if new circumstances appear to require it. We have naturally been influenced by the availability of clinical material on the spot, and the special Orthopaedic, Thoracic, and Facio-maxillary and Plastic Units at Hill End Hospital, where most of this work has been done, have provided many of the cases.

One hundred and ninety-eight patients were treated by the local application of penicillin and 18 by systemic administration. Most of them fell into the following clearly defined groups: skin diseases (75 cases), wounds of the skin and soft tissues (70 cases), breast abscesses (15 cases), infections of the mandible (20 cases), and other infections of bone (34 cases). These various groups are described in the series of articles that follows, written by those who were responsible for the treatment of the patients concerned. A few cases could not be placed in any of these groups, and as in several the results of treatment are of interest, these will be described briefly.

The local application of penicillin to the eye in three cases of iritis gave results which strongly support the suggestion that penicillin may diffuse through the cornea in amounts which are of therapeutic significance. The first was a patient with gonococcal iridocyclitis. He was apparently cured after ten days' treatment, but later relapsed. A further course of treatment lasting five days was again successful, and there has been no further relapse. The second and third cases were of iritis of unknown aetiology, and both were apparently cured within a week. It would be unwise to draw any definite conclusions from so small a series, but in the light of previous experience with this type of infection it seems extremely probable that the results obtained were due to the diffusion of penicillin through the cornea. Three cases of conjunctivitis—two chronic, one acute—were also treated by local application with outstanding success. The observations on iritis were made by our colleague Major Seymour Philips.

In two cases of chronic otitis media instillation of penicillin solution was associated with the disappearance of penicillin-sensitive organisms from the discharge, and apparent clinical improvement. In both, however, the condition relapsed within a day or two of cessation of treatment. In one case of acute bilateral otitis media recovery appeared to be hastened, and was complete after seven days of treatment.

Sixteen patients with acute empyemata were treated by the aspiration of pus and replacement with penicillin solution. One or two intrapleural injections of from 15,000 to 30,000 units were sufficient to sterilize the pus; but to obtain a good functional result subsequent drainage of sterile pus was usually found to be necessary. Details of these cases will be published at a later date by Mr. Tubbs, who is responsible for this part of our investigations.

Seventeen patients were given penicillin by one or other of the systemic routes. Nine of them were cases with bone infection, and these are described in one of the articles which follow. Of the other 8 cases some were treated during the early stages of our investigations, before a clear policy was established of the lines along which research could most profitably be directed. Others were chosen because the prognosis without penicillin appeared to be hopeless, and the trial of new methods of administration was therefore justified. Four were suffering from staphylococcal septicaemia. In all of them the infecting organism was a coagulase-positive *Staph. aureus* which was penicillin-sensitive. The two cases which were first treated were critically ill with multiple abscesses and

yet no leucocytosis. In both adequate bacteriostasis in the blood was maintained by the daily administration of approximately 120 units, and the blood cultures remained negative. Although a total of 2 million units in 23 days was given to the first and 3 million units in 18 days to the second, both patients died. On post-mortem examination both were found to have multiple abscesses which contained living staphylococci. In both a large abscess was present under the muscles of the thigh; in the first case this contained at three pints of pus, and in the second about one pint.

In the third patient, who was also critically ill with staphylococcal septicaemia, systemic administration was combined with energetic local treatment; abscesses in the arm and leg and a suppurative pericarditis were drained and penicillin solution instilled. The patient made a complete recovery.

The fourth case of staphylococcal septicaemia had various transitory signs which suggested cerebral abscess, though localization of it was not possible. He appeared to respond well to systemic treatment, which cured the septicaemia, but definite localizing signs subsequently appeared, and a subdural abscess and a cerebral abscess were successfully drained. Both abscesses contained *Staph. aureus*.

Thus of 4 cases of staphylococcal septicaemia 2 were fatal. Our lesson to be learned from the two fatal cases is that penicillin does not replace surgical drainage, and when pus forms in any quantity it must be evacuated. They may be interpreted in a more general way as indicating that penicillin cannot be expected to save even a case of staphylococcal septicaemia; we believe that the 100% recovery rate reported by Florey and Florey (1943) is more than will usually be achieved. To judge by other reports, the prognosis can be affected adversely in several ways: the development of endocarditis, which was found post mortem in one of these cases, is a particularly unfavourable feature.

The fifth case was one of bilateral sulphonamide-resistant streptococcal pneumonia of six weeks' duration. The outlook appeared to be hopeless, but the patient recovered after 750,000 units of penicillin had been given by the intravenous route.

The sixth case was one of actinomycosis of the chest wall and lung. The sensitivity of the organism was about one-fourth of that of the standard Oxford staphylococcus. 700,000 units of penicillin were given over a period of seven days. The patient died at the end of this period from *Ps. pyocyanea* septicaemia and pyaemia (The source of infection was the intravenous drip.) Necropsy showed extensive pulmonary actinomycosis. The fungus colony in section stained poorly and appeared to be disintegrating. This may have been the effect of treatment.

The seventh case was that of an infant with staphylococcal peritonitis and perinephric abscess. The outlook appeared quite hopeless, and a drip containing penicillin was given into the marrow of the tibia. The patient died, and a post-mortem examination showed no evidence of damage to the marrow at the site of injection.

The eighth patient was a child with pneumococcal meningitis associated with bilateral infection of the mastoids, which had been drained. 800,000 units of penicillin were given systemically and 30,000 units by cisternal, ventricular, or lumbar puncture. There has now been no evidence of infection for two months, but the child remains semi-comatose, and it seems likely that, although penicillin has affected a "cure," there has been permanent damage to the brain. We understand that others have had similar experiences in the treatment of meningitis with penicillin. The rapidity with which penicillin may pass from the cisterna magna to the ventricles of the brain was well illustrated in this patient: one and a half hours after 5,000 units had been introduced by cisternal puncture the ventricular fluid inhibited the growth of the standard staphylococcus in a dilution of 1 in 40.

The cases which have been described form a small and relatively unimportant part of the work of our centre. Much more was learned from the series of carefully chosen cases which are described in the articles which follow.

The penicillin used throughout these investigations was supplied by the Therapeutic Research Corporation through the Medical Research Council and Ministry of Supply.

We wish to express our indebtedness to Prof. H. W. Florey and his colleagues at Oxford, who at the outset of the work of the Penicillin Clinical Trials Committee placed their unique experience at our disposal and thus enabled these studies to be begun.

## EXPERIENCES IN THE SYSTEMIC ADMINISTRATION OF PENICILLIN

BY

H. V. MORGAN, M.B., B.Ch., M.R.C.P.

RONALD V. CHRISTIE, M.D., D.Sc., F.R.C.P.

AND

I. A. ROXBURGH, M.B., B.Ch.

Systemic treatment depends for its success upon the maintenance of an adequate concentration of penicillin in the blood stream. This may be achieved by either continuous drip transfusion or intermittent injection. Neither of these is wholly satisfactory.

## Continuous Intravenous Drip Transfusion

30,000 units of sodium penicillin were dissolved in 1 pint of fluid; transfusion of this amount in 6 hours was considered a suitable initial rate for adults. This dose of penicillin was reduced in the case of younger patients, and subsequent dosage was controlled by blood-titre estimations. The fluid intake was regulated according to the patient's needs. Penicillin was usually dissolved in 4% dextrose in 0.18% saline, but was sometimes added to blood for transfusion. The standard practice was to expose the vein and insert a cannula. A needle was used where it was likely that treatment would be of short duration.

Details of the cases treated by this method are given in Table I. The word "thrombosis" in the table refers to cases in which the drip stopped without rise of temperature or

regarded as an indication for stopping the transfusion without delay. Though impurity of the penicillin probably was largely responsible for this complication, the evidence in Table I does not incriminate any particular batch. The condition generally subsided very rapidly when the transfusion was discontinued, but one case (H. R., who was suffering from extensive thoracic actinomycosis) died of a septicaemia due to *Ps. pyocyanea*, with the primary focus of infection at the site of the transfusion.

Impairment of renal function may lead to retention of penicillin in the blood, so that an adequate concentration may be maintained with much smaller doses (Rammelkamp and Keefer, 1943). This was illustrated by the following estimations of blood titre made in the case of a woman (Case N. M. 3) whose urine contained many red blood cells and granular casts and in whom the blood urea was 56 mg. per 100 c.cm. She had been receiving 30,000 units by intravenous drip transfusion six-hourly. Administration was stopped at 8.15 a.m. and blood removed at intervals subsequently:

Time	Dilution of Serum producing Complete Bacteriostasis	Dilution of Serum producing Partial Bacteriostasis
8.15 a.m.	1 in 32	1 in 64
9.45	1 in 32	1 in 64
11.15	1 in 8	1 in 16
12.45 p.m.	1 in 4	1 in 8
2.15	1 in 4	1 in 8
3.45	1 in 4	1 in 8
5.15	1 in 4	1 in 8
6.45	1 in 4	1 in 8

A specimen taken at 9.45 p.m. showed no bacteriostasis in any dilution.

evidence of active inflammation. It will be seen that a number of these transfusions were stopped prematurely, most commonly through the development of thrombophlebitis. This occurred after varying periods, but on an average after about 100 hours. In spite of inflammation extending up the vein, the fluid sometimes continued to drip; thrombophlebitis should, however, be

Calcium penicillin was administered intravenously in one case (E. W.), first as a single injection, and afterwards by continuous drip transfusion for 24 hours. There were no ill effects, no evidence of delayed excretion when compared with a control dose of sodium salt, and no rise in serum calcium level.

The advantages of continuous intravenous transfusions were: (1) continuous maintenance of adequate blood titre; (2) combination with parenteral fluid administration, which was sometimes indicated.

The disadvantages were: (1) frequent and painful thrombophlebitis; (2) the method was expensive of veins, especially when these were cannulated and made useless for future occasions.

#### Intermittent Intramuscular Injection

A dose of 15,000 units 3-hourly was adopted as the standard adult dose. Table II shows a series of courses of these injections. It will be seen that the reactions of the patient, both general and local, varied considerably from case to case. The cases, which are arranged chronologically in the table, show that on the whole the later batches of penicillin were better tolerated. Not only the degree of impurity of the preparation, but also the condition of the patient and the volume of individual injections, appeared to have a bearing on toleration of the method.

The mere dislike of an intramuscular injection of any kind repeated every three hours, day and night, accounted for strong subjective reactions against the method even when inflammation was slight. There was always pain after the injections, even when these were "well tolerated." This lasted for varying periods, and in the severer instances until the next injection. Pyrexia in patients otherwise afebrile was noted in two cases (J.P. and F.S.); the former felt ill and looked ill.

The advantage of this method was its simplicity. The disadvantages were: (1) Pain, especially if injections had to be confined to one site. (2) Disturbance of the patient. The ruthless regularity of a painful injection every three hours was more than several of our patients could bear. (3) The rise and fall in blood titre (perhaps not a disadvantage).

#### Drip Transfusion into Bone Marrow

It was felt that this route should be tried as a possible alternative to the two routes already considered. Five such transfusions were set up, the method described by Tocantins and O'Neill (1941) being used. The details of these are given in Table III. Dextrose-saline was employed in all of them.

TABLE III.—Administration by Drip Transfusion into Bone Marrow

Case	Age	Batch	Units Given	Site	Duration in Hours	Reason for Stopping

D.P. (2)	6	"	22,500	R. tibia	48	"
D.V.	24	"	30,000	Sternum	2	"
P.R.	14	"	25,000	R. femur (site of infection)	7	Leakage

It was most difficult to run in more than one pint through the sternum. The stoppages at this stage cannot be attributed to the penicillin; rather were they due to difficulties inherent in the method itself. Tibial transfusion was employed on two occasions. The second transfusion, although it lasted 48 hours, could not be made to run at a rate adequate to introduce all of the required dose. There are bound to be difficulties in the systemic treatment of infants; the method therefore was encouraging enough to warrant further trial. Samples of bone marrow from sternum and tibia were examined before and after transfusion, and showed no changes which could be ascribed to penicillin.

In Case P.R., a patient with osteomyelitis of the upper end of the femur, a sternal needle was introduced (at exploratory operation), through a drill-hole, into the medulla of the infected bone. A drip transfusion was subsequently established, using this route, but the fluid leaked back along the track of the needle, and it was therefore discontinued. The needle was left in position and used for four-hourly injections, as a result of which an adequate blood concentration was obtained. Some local pain was felt. The value of this method was doubtful.

#### Continuous Intramuscular Drip Transfusion

In view of the disadvantages of the foregoing methods, and at the suggestion of Dr. Valentine, we employed intramuscular transfusions on 6 occasions. The same dose of penicillin was

used as for the intravenous route. The medium employed in all cases dextrose-saline. It was found that two pints; fluid per 24 hours was a suitable rate of flow, though Billimore and Dunlop (1940) stated that larger amounts of fluid could be given if that be the object of the transfusion. An ordinary intramuscular needle was used with an improvised wire frame for supporting it in position. The results are recorded in Table IV.

TABLE IV.—Administration by Drip Transfusion into Muscle

Case	Age	Batch	Units Given	Pints per 24 Hours	Site	Duration in Hours	Reason for Stopping
P.R.	14	TRC10	408,750	3, 2	Outer side of L. thigh	164	Adequate dose given
J.B. (1)	14	"	35,500	2	"	20	Leakage
J.B. (2)	14	"	518,000	2	"	237	Local abscess
A.S.	19	"	383,000	3, 2	Outer side of R. thigh	80	Pulled out
R.P. (1)	12	"	348,750	2	Outer side of L. thigh	105	Local abscess
R.P. (2)	12	"	135,000	2	Outer side of R. thigh	38	Adequate dose given

It will be observed that all the patients were young. We found that the daily administration of three pints by this route was very apt to cause leakage back along the track of the needle. Restriction of the intake to two pints by transfusion and to three pints by mouth stopped this satisfactorily.

Local abscesses around the site of the needle formed in two cases. Culture of the pus produced a growth of coliform bacilli. In the case of J.B. the blood titre fell so that no detectable penicillin was present; absorption from the abscess cavity was presumably very slight. It should be possible to avoid this undesirable complication by improved methods of anchoring the needle, prevention of any leakage, and removal of the needle at the first signs of any inflammation. Possibly, also, elevation of the limb would help by avoiding stasis; the abscess in R.P. was at the most dependent part of the thigh rather than centred round the needle. These two abscesses had to be opened, but they healed in about three weeks.

The method was almost pain-free, and swelling of the thigh was slight provided the rate of drip was kept constant. Improvements in technique are now being investigated, with encouraging results.

The advantages of the method are: (1) continuous maintenance of adequate blood titre; (2) comparative freedom from pain; (3) availability of numerous sites for transfusion, poor musculature being apparently no bar to the method.

The disadvantages are: (1) tendency to local infection and abscess formation; (2) possibility of having to restrict total fluid intake.

#### Summary

The complications which may arise when penicillin is administered by intramuscular injection and by continuous intravenous and intramuscular drip transfusion are described. Each method has its advantages and disadvantages, and may be the best for any particular case.

It is possible that drip transfusion into the bone marrow of the tibia may be of value in the administration of penicillin to infants.

The Universities' Federation for Animal Welfare (UFAW), in response to a demand, has begun the compilation of a handbook on the care and management of the smaller laboratory animals. The secretary is Dr. F. Jean Vinter, 284, Regent's Park Road, Finchley, N.3. Various sections of the book are being drafted by research workers having appropriate special knowledge, but the Federation wishes to supplement the drafts with information derived from a wide range of sources. It is accordingly sending a list of subjects to all licensees under the Cruelty to Animals Act, 1876. Inquiries are invited from non-license-holders, some of whom might help in this undertaking. The work as a whole will be submitted before publication to a small number of eminent men of science.

## SURGERY AND PENICILLIN IN MANDIBULAR INFECTION

BY

RAINSFORD MOWLEM, F.R.C.S.

This series of 21 cases of infection in connexion with bone is too small to justify detailed analysis, but it may help to clarify the part which penicillin can be expected to play. The cases fall into two groups. In the first, infection has been anticipated after surgery. The use of penicillin has been withheld until the presence of sensitive bacteria has been shown. This has been done in an attempt to evaluate the effects of penicillin under conditions of bacteriological control, and has sometimes caused an undesirable delay. The second group comprises cases of well-established bone infection, all of which have been subjected to full bacteriological investigation, and all of which have been treated by radical surgery and penicillin.

One other case is included for the moral it points.

**Case 1331.**—Soldier aged 53. Presented a two-months-old sinus in the iliac crest, with induration of the surrounding tissues. Haemolytic streptococci ++; *Staph. aureus* ++. Penicillin 1,000 units was injected daily for ten days, with improvement in the surrounding soft tissue but no change in the sinus or its bacteriology. At operation a small sequestrum was found in a cavity lined by fibrous tissue, about 3/8 in. thick.

It is not to be expected, in such circumstances, that even if sterility can be obtained it will automatically be followed by healing. The fibrosis and its resultant avascularity are the determining factors, and not the infection, and this will be true of many established bone infections.

### Group I

This consisted of 4 post-operative cases, in all of which infection was either anticipated or was causing early reaction. In all of them immediate bacteriological and clinical control was obtained, and was followed by satisfactory healing.

**Case 1629.**—Soldier aged 31. Sept. 13, 1943: Resection of the left side of the mandible from the canine tooth to the temporomandibular joint, for an infected multilocular cyst of the whole area. Nov. 8: Chip bone grafting for complete restoration, in spite of a persistent sinus into the mouth. A penicillin tube was inserted along the upper margin of the grafts. Nov. 11: Cheek puffiness ended. Fluid withdrawn from the tube shows *Staph. aureus* ++. Penicillin 1,000 units in 1 c.c.m. injected daily. Nov. 15: The local signs of infection had disappeared, and aspirated fluid was sterile. The next day penicillin was discontinued, and recovery was complete.

It is felt that penicillin contributed very materially to a speedy and uncomplicated convalescence.

Two other bone-graft cases—one with exposure to the surface, and the other with a sinus into the mouth—were treated. In the former satisfactory healing was obtained, but in the latter a few chips of the graft were lost, though the greater number survived. This loss may have been due either to the late and inefficient application of penicillin or to inadequate drainage.

In the fourth case most of the right side of the mandible was resected for an odontoma. In spite of drainage the resultant cavity filled with blood clot and on the sixth day swabs showed haemolytic streptococci ++, *Staph. aureus* ++, coliforms +. 6,000 units of penicillin were injected in the next three days, and thereafter penicillin cream (400 units per gramme) was applied to the drainage opening. On the 12th day the wound was dry and healed.

In this series, therefore, the evidence points to early bacterial control with consequent normal healing, and no local deleterious effects have been seen.

### Group II

This comprised 16 cases of osteomyelitis of the mandible. In all of them infection has been gross and well established, and penicillin has been used in conjunction with radical surgery. Since surgery, other than drainage, is not often adopted, it may clarify the position to state the considerations on which it is based.

Osteomyelitis of the mandible is a relatively rare condition which may—especially in children—arise from blood-borne

infection, but which more frequently is preceded by the extraction of teeth. The cause of the former condition is clearly understood, but the latter type is commonly attributed to less well defined factors. "Diminution of local immunity" and "specific organismal infection" have both been suggested. The latter condition appears to be incapable of proof, and it has so far been impossible to recover from the infected mandible any organisms which can be shown to differ from those present in the normal mouth. In this series the following organisms in various combinations have been encountered: haemolytic streptococci and *Staph. aureus*, both aerobic and anaerobic, pneumococci, *Strep. viridans*, *H. influenzae*, coliform bacilli, and a host of lesser Gram-negative organisms. These may all occur in the normal mouth as well as in the infected jaw, and if their presence were the important factor one might expect massive bone infection to follow almost every dental extraction.

"Local low immunity" is meaningless if it envisages a condition in which otherwise normal tissues become incapable of resisting bacterial invasion by reason of some unspecified cellular change. At the same time there must be some factor which determines whether or not a fairly constant type of mouth infection shall invade the bone. It is suggested that this factor is the local vascular system, which is the key to the mobilization of the defence mechanism. If the potent factor is a vascular one, it is further suggested that thrombosis is the primary disaster. This may be caused either by direct trauma to the inferior dental vessels during the removal of a tooth or by the central extension of thrombosis in the vessels supplying either a tooth root or the surface structures. Occlusion of the main vessels will create a large central area of bone of reduced vitality in which the secondary bacterial invasion is incapable of being withstood. It is obvious that the further back along the vessel this thrombosis extends the greater will be the disaster, and clinical findings tend to bear this out. Though thrombosis is often seen at operation, it is almost impossible to say whether it has preceded or followed the infection, but the probability of its being the primary cause is evidenced by the following:

(a) Mandibular bone infection is rare after the extraction of incisor teeth, and in this area it is usually localized. As one goes further back along the tooth-bearing ridge both the probability and the severity of infection increase. This variation would seem to be dependent upon anatomical consideration of the vascular distribution.

(b) The extraction of deciduous teeth is seldom followed by infection, not because of any difference in the bacterial flora of the mouth in early life, but because damage to the inferior dental vessels is unlikely. The roots of children's teeth are not in close approximation to the vessels, and may be separated from them by the up-growing secondary dentition.

(c) Osteomyelitis of the superior maxilla following dental extractions is almost non-existent. The blood supply of this bone is segmental and vertical, and is incapable, in its periphery, of complete occlusion. The bacteriological state of the mouth must just as often be as potentially dangerous as in extractions of the lower teeth, but the probability of infective invasion remains infinitely remote.

Once medullary infection is established it passes through an acute primary phase to become a chronic condition. This is due partly to its enclosed position, but to a greater extent to the density of the surrounding bone. This bone, because of its relative avascularity, is incapable of rapid inflammatory response, and is often extruded as a sequestrum after many months. The problem is to remove the devitalized, thrombosed, and infected medullary bone, to eliminate that part of the dense cortical bone which cannot resist the spreading infection, and to leave behind only those areas which have an adequate blood supply to enable them first to deal with residual organisms and later to regenerate new bone.

Operation therefore consists in the subperiosteal excision of the lower border of the bone, together with the outer plate and all the infected medullary area. This frequently leaves a lingual plate less than 1/8 in. in thickness and only about 3/8 in. in vertical extent (Fig. 1). It has sometimes been argued that the exposure of uninfected bone by such a clearance would result in further osteomyelitis. This is not the case in such virulent infections as are encountered in acute mastoiditis, and does not seem to occur in the mandible if only vascular bone is left behind. Until

the advent of penicillin the overlying soft tissues of the cheek were then packed away from the bone and the cavity allowed to granulate from its depth. The sulphonamide group did much to control infection, but packing still seemed necessary.

FIG. 1.—Schematic representation of osteomyelitis on the left side and the type of excision and the site of penicillin tubes on the right side.

When penicillin became available it was decided to continue this radical surgery with closure of the soft tissues. This has three advantages: (a) The soft tissues of the cheek may be closely approximated to the underlying bone, and can be expected to contribute to vascular ingrowth. (b) The closed cavity not only excludes secondary infection but also retains the penicillin, which is thus permitted to exercise almost continuous action. (c) Primary instead of delayed healing is obtained. Such a result in established bone infection presents an old and time-consuming problem in an entirely new light.

The technique which has been used in the cases here reported therefore consists in extensive surgical removal of bone as described above. During operation, bacteriological swabs taken from the centre of the infected area are sent for culture and penicillin-sensitivity test. Two small-bore tubes are then inserted through separate stab wounds—one to run along the upper border of the residual bone and the other along the lower edge. The wound of access is then closed without drainage even though it has extended through an abscess cavity.

Within about 18 hours a bacteriological report is available and penicillin treatment is begun. The usual dosage is now 1,000 units in 1 c.cm. into each tube every 24 hours. Immediately before each injection the cavity is aspirated through the penicillin tubes, and any resultant fluid sent for bacteriological investigation and penicillin-inhibition test. Treatment is continued until the wound is healed—on the average, ten days.

There is considerable similarity between all the cases in the group, and only two—one recent and one old—will be quoted at length.

**Case 1628.**—Soldier aged 21. May 1, 1943: Reported sick with a boil on the chin and swelling of the left side of the neck. Admitted to a hospital on May 12 with the original boil healed, but with an increase in the swelling of the neck. This was incised and three teeth were removed. Transferred to the Plastic Unit, July 9. He then presented a generalized swelling of the mental region with an extension to the left side. There were several recent scars and a discharging sinus in the neck. In the mouth, pus was welling up through two tooth sockets and through several fistulae. July 12: Operation. Extraction of 54321/1237. The mandible was then exposed from below and the lower margin removed almost as far back as the angle on each side. Excision of the full vertical extent of the outer plate revealed necrotic tissue occupying the medullary space. This also was removed, leaving a thin shell of normal bleeding lingual lamina. Two penicillin tubes were inserted and the wound closed. Finally the gum at the site of the extracted teeth was trimmed and sutured, thus completely closing the cavity.

July 13: Bacteriological report on the swab taken at operation showed penicillin-sensitive *Staph. aureus* + + +. Penicillin 1,000 units 1 c.cm. injected into each tube twice daily. July 21: Aspirated fluid has been sterile for the past five days. All stitches removed, a sound suture line on both the mucous and the skin. Aug. 5: Discharged to a convalescent home. On Sept. 23 returned to duty, wearing dentures with comfort and showing negligible scarring.

**Case 1318.**—An elderly woman giving a history of swelling of the right side of the face, starting early in 1941. Has spent months in hospitals, and has had extractions of roots, drainage of abscesses, and removal of sequestra. Examination (May 18, 1943) showed a swelling of the whole body of the mandible, with mucous sinuses in the mouth and two discharging wounds under the chin. May 22: The mandible was exposed from the right coronoid notch to a point an inch above the angle on the left side. The lower margin and the outer plate were excised over this area to expose a cavity in the mental region about  $2\frac{1}{2}$  by 1 in. containing a sequestrum which was in fact a circumscribed area of osteitis fibrosa. In the region of the angle and ascending ramus on the right was a similar area of osteitis fibrosa, which was uninfected. In less degree the same condition was present on the left. All abnormal bone, infected or not, was removed, and the wound sutured, except for  $1\frac{1}{4}$  in. at the posterior end on each side. (This was the first case treated with penicillin, and the only one in which tubes were not inserted.)

FIG. 2.—Case No. 1318. Occlusal radiographs showing: (a) an area of osteitis fibrosa lying as a sequestrum in the mandible; (b) appearance of the same jaw seven months after excision and penicillin treatment.

A bacteriological swab showed haemolytic streptococci + + anaerobic *Strep. viridans* + +, and monilia. 4,000 units of penicillin were injected for the first two days, and thereafter 2,000 units a day for the next five days. May 27: Sutured wound healed, though the posterior sinuses were still open but sterile. June 22: Spontaneous discharge of much pus, together with one small sequestrum evidently overlooked at operation. Cultures sterile. June 29: A wound, both on the surface and in the mouth, soundly healed. Feb. 19, 1944: Review. There has been no further disturbance. The scars are satisfactory, and the radiograph shows good bone regeneration, with no evidence of either infection or residual osteitis fibrosa. (Fig. 2.)

## Complications

1. The deliberate avoidance of drainage does not prevent the continuance of soft-tissue breakdown, and an accumulation of pus may need evacuation. This has so far been found to be sterile, and the resultant sinus closes rapidly.
2. Persistence of discharge, sometimes associated with a change in bacteria, has occurred twice. In each instance it has been due to incomplete removal of affected bone. One case was subsequently reoperated on with success. The other, which acquired a coliform infection about the tenth day, became much more extensive, and has not yet been subjected to further operation.
3. In two cases removal of all infected bone has created a section of mandibular continuity. In one elderly woman no fixation was necessary, and satisfactory union occurred. In the other case the division was close to the condylar neck, and splintage was applied. It is as yet too early to assess the final result, but union seems to be progressing.
4. When the main infection lies on the lingual side of the jaw the detached muscles of the floor of the mouth swing away from the bone, and in these cases closure of the skin alone leaves a large cavity. It may not always be wise to close the whole wound in these circumstances, but rather to pack with penicillin gauze. Although this may result in bacteriological control, there is no reason to expect much increase in the rate of healing.

## Summary

It is pointed out that penicillin is unlikely to give bacteriological control to the presence of sequestra or unfavourable surgical conditions. It is therefore no substitute for adequate surgery.

In four cases in which penicillin has been used as a "prophylactic" there is evidence that the infection has been rapidly controlled without any undesirable local effects.

A conception of the dominant role of vascular disaster in the causation of bone infection is advanced, and a technique for treatment of osteomyelitis of the jaw based upon this is described.

The adjuvant effect of penicillin has led to the conversion of the original open method to a closed one, with all the advantages this confers. In the 16 cases so treated elimination of all penicillin-sensitive organisms, satisfactory soft-tissue healing, and good regeneration of the bone have taken place, so that recovery from what has hitherto been an extremely chronic condition has been effected in an average of about 30 days.

I am indebted to the Penicillin Clinical Trials Committee of the M.R.C. for supplies of penicillin used in this series; to Prof. L. P. Garrod for constant supervision of the bacteriological aspect of these cases; to "Bundles for Britain," who provided a generous fund for the maintenance of the laboratory in which the work was carried out; and to all members of the Plastic and Jaw Unit at Hill End Hospital, who have been of so much assistance in the clinical control of the cases. To all of them I desire to express my very sincere thanks.

## PENICILLIN IN BONE INFECTIONS

BY

IVOR M. ROBERTSON, F.R.C.S.D.

Apart from the observations of Florey and Florey (1943) on the treatment of acute osteomyelitis, there is little published information about the use of penicillin in orthopaedic surgery. An attempt has therefore been made to explore its value further, and the results in 34 cases will be described, nine of which received systemic and the remainder only local treatment.

## Acute Haematogenous Osteomyelitis

This group comprised 7 cases, all in children. With one exception penicillin was used as an adjunct to surgery; the wounds following surgical exploration were packed lightly with petroleum jelly gauze and enclosed in plaster, a window being cut to allow of inspection and taking swabs for culture. Systemic penicillin treatment was given by various routes, dosage being calculated roughly according to body weight, and based on an adult dose of 120,000 units daily. The methods of administration used are described by Morgan, Christie, and Roxburgh (p. 515).

**Case 1.**—K. P.; female, aged 12. Acute osteomyelitis of lower third of right femur of 3 days' duration. Coagulase-positive *Staph. aureus* in blood and pus. Treated by incision of subperiosteal abscess and drilling of femur. Penicillin treatment began on fourth day of disease (1,031,000 units in 13 days). On completion of systemic treatment the wound was packed for the next 24 hours with gauze soaked in penicillin solution. Thereafter, decreasing amounts were instilled into the wound daily. Penicillin cream was employed in later stages of healing. The total amount used for local treatment was 62,000 units. Wound sterile on 14th day; complete epithelialization on 32nd day. X-ray changes minimal.

**Case 2.**—J. B.; male, aged 14. Acute osteomyelitis of lower third of right femur of 8 days' duration. Blood culture and pus: coagulase-positive *Staph. aureus*. Treated by incision of subperiosteal abscess and drilling of femur. Penicillin given systemically (860,600 units in 14 days). Effusion into right knee-joint aspirated at same operation (culture, *Staph. aureus*). Joint aspirated on 4 occasions on alternate days and 10,000 units penicillin injected. After 4th aspiration the contents were sterile. Knee recovered full function. Wound sterile on 14th day; completely healed on 43rd day. X-ray changes minimal.

**Case 3.**—P. R.; female, aged 12. Acute osteomyelitis of upper third of right femur of 31 days' duration. Coagulase-positive *Staph. aureus* in pus from wound. Treated by exploration of upper third femur and drainage of large subperiosteal abscess. Penicillin given systemically (1,087,000 units in 20 days). Further exploration 15 days later. Trochanter region of femur opened up by guttering. Wound healed in 100 days. Further exploration became necessary. Gross x-ray changes present. Penicillin therapy was restarted; 660,000 units given intramuscularly over period of 11 days. Wound healing.

**Case 4.**—R. P.; male, aged 12. Acute osteomyelitis of lower third of right ulna, upper third right humerus, lower third of right and left femur of 14 days' duration. Coagulase-positive *Staph. aureus* in blood culture and in pus from superficial abscess. Extremely ill. Temperature 102°; pulse 110. Bronchopneumonia present. Pain and tenderness were not localized to areas indicated above, but were associated with effusion, pain, and stiffness of all neighbouring joints. Superficial abscess discharging on forearm. No indication as to the site of primary focus, and bony lesions were never localized enough to merit surgical incision. Treated by intravenous penicillin; later changed to intramuscular drip. Total amount given, 761,250 units in 10 days. Complete recovery in 60 days. X-ray changes minimal.

**Case 5.**—J. B.; male, aged 10. Acute osteomyelitis of lower third of right femur of 2 days' duration. Coagulase-positive *Staph. aureus* in pus from wound. Treated by incision and drilling. Penicillin given intramuscularly (434,350 units in 9 days). Wound granulating. Temperature normal. On the 6th day after treatment the left leg became tense and painful. There was a rise of temperature, which continued until the intramuscular drip was discontinued. Temperature fell immediately, and has remained normal ever since. Wound epithelialized in 45 days. X-ray changes minimal.

**Case 6.**—B. W.; male, aged 5. Acute osteomyelitis of upper third of right tibia of 10 days' duration. Blood culture sterile. Coagulase-positive *Staph. aureus* in pus. Treated (before admission) by sulphathiazole (14 g.). When admitted, treated by incision and drilling. Penicillin given intramuscularly (440,000 units in 11 days). On the 6th day of intramuscular treatment the left leg became tense and painful. This was accompanied by an inguinal adenitis and rise of temperature. On 10th day wound sterile. Secondary suture performed. Small rubber tube inserted through upper end of wound. Penicillin instilled daily for 11 days (36,000 units). Wound soundly healed in 26 days. X-ray changes minimal.

**Case 7.**—D. E.; female, aged 18 months. Acute osteomyelitis of upper third of left tibia of 1 day's duration. Coagulase-positive *Staph. aureus* in pus. Treated (before admission) by sulphathiazole (4 g.). When admitted, treated by incision and drilling. Intramuscular injections of penicillin given 3-hourly (350,000 units in 12 days). Still under treatment.

**Comment.**—Case 4 differs from the rest in that no surgical treatment was employed. This boy had a positive blood culture and a severe infection which might well have been fatal. A positive blood culture was also obtained in Cases 1, 2, 5, and 6, in which the disease had existed for 3, 8, 2, and 10 days respectively. Case 3, with a pre-treatment duration of 31 days, is the only one in the series to run a prolonged course, and is not yet well.

These results may be compared with those of McKeown (1943), who describes 26 cases treated with sulphathiazole and various types of surgical intervention. The 17 cases treated with sulphathiazole and by bone-drilling at an early stage of

the disease gave the best result of any method used, and reduced the duration of the disease by 60%. Of the 17 cases, none was healed completely under three months. Most of the cases healed in three, four, or five months, but the average was six months. Four cases in our series of six (i.e., excluding Case 4, which did not require surgical intervention) healed completely, with minimal x-ray changes, in 32, 43, 45, and 26 days respectively. These four cases have encouraged us in the hope that the duration of the disease may be further curtailed by the use of penicillin.

### Local Treatment

#### (a) Chronic Haematogenous Osteomyelitis

In the local treatment of this condition penicillin was used in three forms: (i) a solution of calcium penicillin in distilled water usually of a strength of 1,000 units per c.cm.; (ii) a cream containing 400 units per gramme in a base consisting of equal parts of lanette wax S.X., petroleum jelly, and water; (iii) powder containing 2,000 units per gramme in sulphanilamide with 5% magnesium oxide added to prevent caking. The position, nature, and extent of the infection had to be taken into account when deciding on choice of preparation and method of application. Cases with sinus formation leading down to infected bone were usually treated with penicillin in solution, instilled either directly into the sinuses or through a small-bore rubber tube or tubes extending well down the sinus. In some cases the tube was withdrawn immediately after each treatment, but in others it was left in place and withdrawn gradually each day. The tubes were kept in position on an average from 7 to 10 days, depending on the bacteria present. Bacteriological examinations were made frequently from the aspirated material.

Cases in which surgical treatment had been limited to sequestrectomy presented a more difficult problem. A bony cavity was usually present, and its position often made retention of penicillin solution extremely difficult if not impossible. In some cases it was possible to maintain a tube in position so that the injected penicillin had some chance of reaching all infected areas. The amount of penicillin injected varied with the size and extent of the bony cavity. From 4 to 10 c.cm. was used on an average. The tube was closed by a spigot to prevent loss, and the instillations were made once every 24 hours.

In many cases closed plasters were used, with a window cut to allow dressing and inspection of the wound. This was restricted as much as possible, the tube being led through the dressings so that the daily injections could be carried out without disturbing the wound itself. Cases with exposed bone, and particularly those presenting a "trough" appearance, were filled with penicillin solution, and retention was maintained by splinting or positioning the limb. In cases that had been "saucerized" penicillin-sulphanilamide powder or cream was used. Applications were made once every 24 hours.

Case 1.—M. H.; female, aged 20. Osteomyelitis of femur of 3 years' duration with wide sinus leading to bone. *Staph. aureus*. Treated by sequestrectomy followed by direct application of solution through tube fixed into sinus. 7,000 units per day for 7 days. Wound sterile after 5 days and healed completely in 3 weeks. (Solution was well retained in this sinus, and fluid withdrawn before a further injection was still active.)

Case 2.—M. J.; female, aged 34. Sinus over right sacro-iliac joint in connexion with old tuberculous joint. Duration, 9 years. *Strep. pyogenes* and *Staph. aureus*. Treated by instilling penicillin solution into the sinus (72,500 units in 13 days). Temporary slight improvement, but relapse after stopping treatment.

Case 3.—W. H.; male, aged 48. Chronic osteomyelitis of femur of 30 years' duration with a large elongated cavity (5 by 1½ in.) on outer aspect of thigh extending to bone. *Strep. pyogenes*, *Staph. aureus*, diphtheroids, and coliforms. Treated by exploration. No sequestra found. Positional flooding of cavity with penicillin solution (131,000 units over 12 days). No improvement.

Case 4.—J. F.; male, aged 19. Chronic osteomyelitis of lower third femur of 2½ years' duration, with several small sinuses and incompletely healed wound of sequestrectomy. Gram-positive cocci, diphtheroids, and *Proteus*. Treated by sequestrectomy. Sinus injected with penicillin solution through catheter (40,000 units in 34 days). Wound packed with cream. Sinuses persisted.

Case 5.—W. B.; male, aged 33. Chronic osteomyelitis of lumbar vertebra (4), with track leading out above left iliac crest; 8 months' duration. *Strep. pyogenes* and *Staph. aureus*. Treated by dilatation of sinus at operation. Tube left *in situ*. Penicillin solution run in through tube (31,000 units in 9 days). Wound sterile in 3 days. Sinus much smaller.

Case 6.—J. S.; male, aged 41. Acute exacerbation of chronic osteomyelitis of 3 months' duration, with cavity in upper end of (2 by 3¼ in.) leading to sinus. *Staph. aureus*. Treated by drill bone and scraping cavity. Wound partially closed and tube left extending down to bone cavity. Penicillin solution instilled (36,600 units in 6 weeks). Sinus healed temporarily.

Case 7.—T. P.; male, aged 19. Chronic osteomyelitis of tibia of a year's duration, with a large open cavity on the ante surface containing stinking pus and with sloughs on its soft walls, exposing bone of upper third, and multiple sinuses. *Staph. aureus* and *Proteus*. Treated by positional flooding with penicillin solution (311,000 units in 41 applications over 3 months). Wound treatment was begun; amputation of this leg had been advised. Limb being immobilized, the solution was retained in the large cavity although this was wide open, and usually preserved its activity or renewed. The exudate lost its offensive smell; the borders of the cavity became clean, and its size steadily diminished until it was almost completely filled up and healed by granulation. Unfortunately, other sinuses discharged, and further sequestrectomies have since been necessary: the patient is still under treatment.

Case 8.—R. N.; male, aged 18. Sinus of right groin due to chronic osteomyelitis of ilium of 6 years' duration. *Staph. aureus*. Treated by instillation of penicillin solution into sinus with catheter *in situ* (32,000 units over 16 days). Discharge sterile on the 12th day. Sinus healed at the end of course of treatment, but leg broke down.

#### (b) Osteomyelitis after Compound Fractures

Five such cases were treated by similar methods, of which brief histories follow together with those of two infected operation wounds.

Case 9.—W. D.; male, aged 30. Small wound on anterior aspect of right leg with bare bone visible, of 6 weeks' duration, the result of a compound fracture of the tibia. *Strep. pyogenes* and *Staph. aureus*. Treated by application of penicillin powder and later cream to the wound (14,300 units in 17 days). Wound was then explored and several small sequestra removed. A rubber drainage-tube was inserted through a separate stab wound and the skin edges closed. Penicillin solution was instilled (136,000 units over 16 days). Tube and stitches were then removed, and the wound, which appeared to be healed, was insufflated with powder. Wound broke down slightly two days later, and was treated with a further 23,000 units of solution. This sinus healed in 15 days and remained healed for two months, when it broke down again.

Case 10.—F. S.; male, aged 42. Long sear on anterior aspect of leg with granulating gutter leading to necrotic bone at lower end, due to chronic osteomyelitis of 19 months' duration, following compound fracture of the ankle. *Staph. aureus* and diphtheroids. Treated by insufflation of penicillin powder (30,000 units in 25 days). Infection persisted.

Case 11.—R. H.; male, aged 21. Gutter-shaped wound of 13½ weeks' duration, 7 in. long, on antero-lateral surface of leg, with bone exposed at lower end, due to compound fracture of tibia. *Staph. aureus* and *Proteus*. Treated by positional flooding with penicillin solution (14,000 units in 2 days). After sinuses had been laid open at operation, powder was used (36,000 units in 18 days). No change in the condition of the wound. Infection persisted.

Case 12 (a).—W. S.; male, aged 36. Cross leg flap to repair skin loss of right leg due to chronic osteomyelitis of 2 years' duration. *Strep. pyogenes* and *Staph. aureus*. Treated by injection of penicillin solution (two doses) into wound and by application of cream (27,000 units in 15 days). Wound rendered sterile.

Case 12 (b).—Further course of treatment undertaken 3 weeks later. *Strep. pyogenes* (Type 27) and staphylococci. Treated by injection of penicillin solution below flap (42,000 units in 2 weeks). Osteitis remained unchanged.

Case 13.—F. L.; male, aged 40. Infection, of 6 weeks' duration, of iliac crest, which was donor site for cancellous bone graft. *Strep. pyogenes* and *Staph. aureus*. Treated by injection of penicillin solution into infected wound (18,000 units in 9 days). Streptococci disappeared in 24 hours. No clinical improvement.

Case 14.—J. G.; male, aged 26. Active sinus of 3 months' duration leading to chronic osteomyelitis of lower third tibia of 2 years' duration following compound fracture. *Staph. aureus*. Treated by introduction of penicillin solution into sinus (24,000 units over 12 days). Sinus closed, but later broke down.

Case 15.—R. T.; male, aged 48. Widely infected wound (7 by 3 in.) of 3 weeks' duration, following bone graft at lower end of tibia. Graft exposed. *Staph. aureus* and *Ps. pyocyanea*. Treated by applying penicillin solution with a spray (32,000 units in 9 days). Infection persisted.

Comment.—The results of treatment by local application of penicillin in cases of chronic bone sepsis have so far proved very disappointing. Of these 16 cases complete healing occurred

one only. In seven there was only temporary improvement, in eight none. At least three factors appear to be responsible for the unsatisfactory results:

1. *Failure of Continuous Application.*—The mechanical difficulties securing continuous action are great. Solution may escape sinuses and often cannot be retained at all in large shallow wounds. Case 7 was an exception: complete immobilization enabled the solution to be maintained in the wound for two months, which steadily proceeded to heal in spite of the presence of a resistant organism (*Proteus*) together with a susceptible one (*Staph. aureus*).

2. *Inaccessibility of the Bone Infection.*—In many cases it seemed probable that the penicillin solution instilled down a sinus or introduced into a bone cavity reached the whole of the infected area, areas of deep osteitis persisting, and only the superficial infection being affected (e.g., Cases 4, 6, and 7). It was shown in Case 9 that bone cavity can be sterilized temporarily, but on the cessation of treatment the infection recurred. Re-infections may occur from the sinus in some instances, but in a number of cases it was observed that the infecting organism was identical with that present in the wound before sterilization (Case 12, *a* and *b*). This suggests that deeper areas of osteitis remained untouched.

3. *The Presence of Dead Bone.*—Regardless of their accessibility otherwise to penicillin, however administered, there were evidently, in some of these cases, areas of bone of which the surgical removal was necessary before healing could occur. In the presence of sequestra, penicillin treatment unaided by surgery has been unsuccessful.

In the group of compound fractures, those cases presenting a guttered wound with gross skin loss and bare bone exposed in the depths were particularly resistant to treatment, the mixed bacterial flora remaining unaltered and the healing of the wound being delayed. (Cases 10, 11, and 15).

It is hoped to improve on these discouraging results by a policy that is now under trial in several cases, results of which are not yet available. This is the more radical removal of infected bone, followed by complete closure, if necessary with the aid of a full-thickness graft, and subsequent instillation of penicillin solution through a tube.

#### Miscellaneous Cases

In this group 12 miscellaneous orthopaedic cases were treated with penicillin—ten locally and two systemically.

##### Section 1—Local

(a) Post-operative wound infections (5 cases). (b) Soft-tissue sinus associated with chronic osteomyelitis of hip (1 case). (c) Infected Steinmann-pin holes (2 cases). (d) Gunshot wound of shoulder region (1 case). (e) Chronic sinus associated with plating of femur (1 case).

(a) Five cases of post-operative wound infections were treated at intervals varying from 3 to 130 days after operation. In all cases the method was to instil the solution by means of a catheter into the sinus twice daily, the total dose varying with the size of the sinus and the duration of the treatment. The average was 39,000 units in 34 days. Two cases healed completely, two showed temporary improvement, and one showed no improvement.

(c) Two cases of infected Steinmann-pin holes were treated. The pin tracks were in the upper end of the tibia just below the tubercle. They were treated by injection of penicillin solution into the track. Complete healing occurred in both cases at the end of 27 and 13 days respectively.

(d) A case of osteomyelitis of left shoulder with chronic sinus resulting from a gunshot wound of the shoulder 10½ months previously, and with a foreign body still in the depths of the wound. This case was treated by surgical drainage and the instillation of penicillin solution by means of rubber catheters into sinuses daily for 25 days (total, 235,500 units). This resulted in a slight improvement in the condition of the wound.

(e) A case of infection in a plated femur treated by local applications of penicillin solution unsuccessfully. The plate was later removed at an operation, and a subsequent course of penicillin therapy was carried out (101,000 units in 13 days, introduced into a catheter fixed *in situ*). Complete healing occurred in 19 days.

##### Section 2—Systemic: Compound Fractures associated with Chronic Osteomyelitis

Case 1.—J. P.; male, aged 38. Deep epithelized trough of 6 months' duration on anterior surface of lower leg with an island of bare bone in centre following compound comminuted fracture of upper end of tibia with gross skin loss. *Staph. aureus*; diphtheroids. *Systemic treatment:*—Intravenous penicillin, 30,000 units per pint of dextrose-saline 6-hourly for 6 days (total, 720,000 units). Dis-

continued owing to thrombophlebitis of long saphenous vein. Intramuscular injections (15,000 units 3-hourly for 4 days; total, 480,000 units). Injections discontinued owing to patient's complaining of severe cramping pains at site of injection. Intravenous penicillin restarted, and given for 3 days (total, 360,000 units). *Local treatment:*—3,500 units of penicillin cream applied to wound daily for 3 days. Systemic treatment had been discontinued. *Result:*—The wound was sterile at the end of the course of treatment and permitted delayed secondary suture of the wound with excision of protruding necrotic bone. Wound remained healed for seven weeks and then broke down. The infecting organisms were identical with those present before sterilization.

Case 2.—F. S.; male, aged 42. Trough-shaped discharging wound (2½ by 1 in.) with bare bone visible at the lower end of tibia of 18 months' duration, following compound fracture-dislocation of ankle. *Coagulase-positive Staph. aureus* and diphtheroids. *Systemic treatment:*—Intravenous penicillin was given, 30,000 units per pint of dextrose-saline 6-hourly for 5 days in left leg (total, 600,000 units). This was discontinued owing to increasing oedema of left leg due to thrombophlebitis. Intramuscular injections (15,000 units 3-hourly for 6 days; total, 720,000 units). This was accompanied by a persistent pyrexia (100–102°) throughout course of systemic treatment. *Local treatment:*—13,000 units of penicillin were applied over a further 25 days in the form of cream. *Result:*—Staphylococci and streptococci had disappeared by the 11th day of systemic treatment, but coliforms persisted throughout. Considerable improvement in the wound permitted further sequestrectomy. Healing has progressed slowly, but no major breakdown of the wound has occurred since.

*Comment.*—The majority of the locally treated cases in this miscellaneous group responded well, possibly because the lesions were of small extent, involving mainly soft tissues, and usually not of long standing. The two cases treated systemically were costly failures: over a million units of penicillin were used in each with little ultimate benefit. This drastic treatment was decided on as an experiment when local application in similar cases had failed. To judge by its results in these two cases, this expenditure of penicillin is unjustified, and long-standing sepsis involving bone must be considered an unfavourable field for treatment, either local or systemic.

#### Summary

Early acute haematogenous osteomyelitis was treated systemically with penicillin in 7 cases with good results: 6 of these were also subjected to orthodox surgical treatment.

Systemic treatment in 2 cases of chronic sepsis following compound fracture was of only temporary benefit.

Local application of penicillin was employed in treating 8 cases of chronic haematogenous osteomyelitis: 7 cases of osteomyelitis following compound fractures, and 10 miscellaneous cases, mainly chronic sinuses. The reasons for the failure of the treatment in many of these cases are discussed.

## THE LOCAL APPLICATION OF PENICILLIN IN SOFT-TISSUE LESIONS

BY

J. N. BARRON, F.R.C.S.

AND

O. T. MANSFIELD, F.R.C.S.

This report deals with cases under treatment in an E.M.S. plastic unit. The surgical treatment of these cases involved reconstructive procedures for various types of tissue loss, under conditions in which the control of infection by pyogenic organisms has always been a predominant problem. The cases reported do not represent the total number treated (45 out of 70), but are chosen only on the grounds that reasonable conclusions can be drawn from them. Of these selected cases seven are detailed in the text as illustrations. Because of the wide variety of conditions treated, a somewhat arbitrary classification is adopted in order to avoid innumerable subdivisions. These can in no way be considered as a series.

#### Group A: Infected Skin Lesions

These consist of infected eczematous, impetigo, the so-called capillary lymphangitis, and similar skin eruptions with pustule

formation. Several have occurred on Thiersch graft donor areas. There were 7 cases in this group, all infected with haemolytic streptococci, staphylococci, or both. All except one cleared up in 10 to 14 days, but some relapsed later. In all cases the preparation used was a cream containing 400 units of penicillin per gramme in a base composed of equal parts of lanette wax S.X., soft paraffin, and water.

**Case 1.**—A soldier aged 29 had a surgical correction of an adherent scar on the dorsum of the right index finger. After operation he developed a staphylococcal eczema round the surgical area, and the infection involved the suture lines. This was sterilized in two days with penicillin and remained sterile for eight days, in spite of which the eruption spread.

The occurrence of an eczema induced by the use of the cream in two subsequent cases provides a possible explanation of this result. One of these later cases had a positive patch test to the cream, the presumed irritative agent being the soft paraffin employed. This is under investigation.

This group of cases suggests that skin lesions infected with penicillin-sensitive organisms respond according to the technique of application. Where the lesions were open and the penicillin had ready access to the foci of infection the results were satisfactory, but in closed lesions temporary improvement was followed by relapse when treatment was stopped. It is possible that careful skin toilet followed by penicillin inunction may prove to be more effective in these resistant cases.

#### Group B: Abscess Cavities

Penicillin solution in a strength of 1,000 units per c.cm. was injected into five abscess cavities. Of the results two were successful, one was doubtful, and there were two failures.

**Case 2.**—A woman aged 22 for whom a cancellous iliac bone graft was used to reconstruct a syphilitic saddle deformity of the nasal bridge. After operation she developed a haematoma in the region of the graft in the nasal bridge. This remained quiescent for seven days and then suddenly became infected. She was returned to the theatre and bilateral drainage instituted. There was a mixed haemolytic streptococcal and staphylococcal infection, which responded immediately to penicillin injected into the cavity, and the drainage wounds were healed in four days. There was no loss of the cancellous bone.

**Case 3.**—A man aged 22 for whom a bone graft similar to that described above was used in the correction of a traumatic nasal bridge deformity. There was a rapid post-operative infection, with pus formation on the third day. At this time bilateral drainage was done and penicillin injection started. The infection was penicillin-sensitive *Staph. aureus*. This treatment was continued for a week with no change in the discharge or the infection, so that penicillin was discontinued. Conservative treatment was advised, and the discharge gradually decreased until a month later a small sequestrum was evident, the removal of which effected rapid healing.

Consideration of these two cases shows that one salient feature was the time of onset of the infection. Advocates of the cancellous-bone-grafting technique hold that this bone derives a primary blood supply from the surrounding tissues and thus survives as a true graft. In Case 2, then, several days had elapsed before infection supervened, so that the bone cells by that time might be considered to have survived the transplanting procedure. Under these conditions the early treatment of infection should tend to prevent sequestration and thus promote the rapid resolution of the infective process.

In Case 3 the disaster occurred before viability was established in the graft, so that in spite of treatment a portion of the bone died and thus perpetuated the infection, which did not clear up until sequestration was complete. The small size of the sequestrum (it was a wafer from the subcutaneous surface of the bone) does suggest that this tissue lends itself favourably to transplantation.

A further inference that can be drawn is that penicillin in the presence of necrotic tissue does not appear to have much influence upon the infection. In this and other similar cases no clinical improvement was demonstrated with the use of penicillin. Thus where a penicillin-sensitive infection does not rapidly respond to adequate application much time will be saved if a search for complicating factors is made.

**Case 4.**—A young soldier was admitted for reconstruction of the chin and incisor region of the mandible, lost as the result of a gunshot injury. The mandible had been made good by a bone graft,

and at the stage under discussion his lower buccal sulcus had been re-made by a Thiersch grafting operation. Owing to a small breakdown in the graft an abscess appeared in the soft tissues of chin. The bacteriology was very mixed, some organisms being sensitive to penicillin and others not. The treatment consisted of filling the cavity via the mouth with penicillin after expression of the pus. Although a small fistula opened on to the skin surface the abscess was healed in six days.

This type of breakdown has in the past been a matter of regret, in so far as many weeks pass before it attempts to heal and considerable scar is left in its train. In the above case it is felt that the early control of infection in this area prevents sufficient breakdown for the wound to become chronic.

The case in this group which has been described as doubtful was a surgically drained subcutaneous abscess in a hand, the organism being a penicillin-sensitive staphylococcus. This case followed the ordinary course resulting from adequate surgical drainage, and did not present any special features during the healing phase.

**Case 5.**—This patient was an 11-year-old boy with a severe phosphorus burn of the leg of three months' duration. The soft tissues on the posterior aspect of the knee-joint had been destroyed, leaving the external femoral condyle visible in the wound. He was critically ill at this stage with an intermittent profuse purulent discharge from an acute pyarthrosis, and an endeavour was made to combat this infection by the local instillation of penicillin into the joint cavity by means of Carrel tubing. This treatment resulted in no improvement, and it was quite obvious that the penicillin did not have access to all parts of the infected joint. The treatment was stopped and traction applied. Slow improvement occurred, and eventually the joint sinus healed.

This case illustrates well the precept that the technique of application must be efficient or the results will be unfavourable. The results of local application are truly local, so that adequate access must be provided.

#### Group C: Acute Spreading Cellulitis

Five cases of acute invasive infection under skin flaps designed for reconstructive purposes were treated by the early instillation of penicillin solution. In all cases progress of the infection was halted and resolution was rapid. Previous experience of this complication with skin flaps, the blood supply of which is necessarily much curtailed, confirms that these results have not been attained by other methods of treatment.

In the second series of cases under this heading 11 insets of tubed pedicle grafts were treated in a similar manner. In five of these loss of tissue resulted which necessitated further surgery; in the other six the insets survived. The controlling factor appeared to be the blood supply of the part rather than the infection. In some of these cases, although the infection was controlled, retrograde intravascular thrombosis continued, with progressive tissue loss.

From the results in this group it is felt that penicillin is of value in controlling infection which the depleted blood supply of the tissue itself would be unable to cope with, and on these grounds the prophylactic use of penicillin may have a wide application.

#### Group D: Superficial Wounds with Skin Loss

In this category there were 17 cases. All were treated with penicillin cream. The variety of these lesions introduces so many extraneous factors that general conclusions are all that can be drawn from them. These conclusions can be illustrated by individual case reports.

(a) Penicillin can sterilize a wound and prevent its reinfection with sensitive organisms. It does not necessarily follow that a wound thus sterilized will heal.

**Case 6.**—A soldier aged 23 was given x-ray therapy three years previously for warts on the right hand. He was admitted for the treatment of a radio-necrosis of the index finger and thumb, the middle finger having already been amputated. During a skin-flap replacement of the dorsum of the index a linear breakdown occurred in a suture line, which became infected with *Staph. aureus*. This was sterilized in two days and kept sterile for 32 days by using penicillin cream. During this time there was no attempt at healing, and a cervical sympathetic block was done. This produced a response in the disorganized vascular system and the wound healed.

(b) If reinfection of a wound occurs after sterilization by penicillin a sensitivity test should be done on the new invader, it may be resistant.

Case 7.—A soldier aged 23 was undergoing total reconstruction of the thumb. A pedicle graft had been raised and transferred to the thenar remnant, and at this stage both ends of the pedicle were attached to the hand. As the result of some slight trauma the pedicle ulcerated and became infected with penicillin-sensitive *Staph. aureus*. Penicillin cream was used as a dressing, and sterility was obtained in five days. The wound remained sterile for 16 days without any clinical change and then became reinfected with *Staphylococci*. Penicillin was continued for 27 days without clinical or bacteriological effect. Finally treatment was stopped and the ulcer eventually healed.

(c) Although sensitive organisms may disappear from culture, the wound may be so infected with *pyocyanens*, *proteus*, or the oliforms as secondary invaders that no clinical improvement is noted or indeed can be expected. This was a common finding, particularly in this group of cases.

(d) Penicillin can be a useful adjunct to surgery, but does not replace it. Certain surgical principles may need modification to comply with the requirements of penicillin application.

### Summary

These experiments with the local use of penicillin to date indicate that we have an effective weapon in the fight against tissue invasion by certain of the pyogenic cocci. The points that emerge are:

1. Early application is most desirable.
2. Efficient technique must be used to bring penicillin into contact with the infective process.
3. Tissues necrosed as the result of infection are removed by natural processes. Many wounds containing slough or sequestra resist sterilization by penicillin. In some of these cases it is probable that attempts at sterilization impede slough removal and so delay healing.
4. Penicillin as an adjunct to adequate surgical technique is a valuable advance in the treatment of wounds infected with sensitive organisms.

## LOCAL TREATMENT OF BREAST ABSCESS WITH PENICILLIN

BY

DONALD B. FRASER, F.R.C.S.

Simple aspiration under local anaesthesia has in some hands given good results in the treatment of mammary abscesses, and it seemed logical to add to this penicillin replacement when supplies became available. A series of 15 consecutive cases has been treated, and case histories, with interpretation of results, are here given.

The technique used was simply to infiltrate the skin with a stab of 2% novocain and to aspirate through a needle with a 20-cm. syringe. Staphylococcal pus is sometimes thick and breast abscesses are notoriously loculated, but by using saline wash-outs when necessary it was usually possible to evacuate them with fair efficiency. The organism in every case proved to be coagulase-positive *Staphylococcus aureus*. No strains resistant to penicillin were encountered. A solution of calcium penicillin in distilled water of a strength of 2,000 units per c.cm. was then injected through the same needle, dosage varying from 2,000 to 20,000 units according to the size of the abscess. Aspiration and injection of penicillin were usually repeated at two-day intervals: the pus obtained on the second and subsequent occasions was usually sterile or nearly so, and, when placed in an agar cup in a plate inoculated with the standard Oxford H. staphylococcus, produced a zone of inhibition indicating that penicillin was still present in effective concentration after 48 hours. I am indebted for the bacteriological investigations to Dr. J. C. Ford.

Except in three of the earlier cases, breast-feeding was discontinued and lactation suppressed by restriction of fluids, mild aperients, and stilboestrol 5 mg. daily for 5 days. The breasts were firmly supported with crepe elastic bandages.

### Case Histories

Case 1.—Primipara aged 23. Painful breast after 5 weeks of lactation. Admitted Jan. 15, 1944, with large breast abscess and

infection involving most of breast. Same day: Aspiration 40 c.cm. pus; 12,000 units penicillin. Jan. 16: Aspiration 16 c.cm. pus; 10,000 units penicillin. Result:—Next day spontaneous discharge from aspiration site and rapid resolution. Home in 8 days.

Case 2.—Multipara aged 30. No recent pregnancies. Two small breast abscesses in past year treated by surgical drainage. Three weeks ago, gradual development of another, involving one-third of the breast above and behind areola. Dec. 28, 1943: Aspiration 7 c.cm. pus; 10,000 units penicillin. Dec. 30: Aspiration 12 c.cm. pus; 8,000 units penicillin. Jan. 1, 1944: Aspiration 14 c.cm. pus. Result:—Remained closed, and on Jan. 14 there was good resolution.

Case 3.—Aged 23. Breast abscess following weaning at 10 months, involving about one-quarter of breast. Duration 8 days. Treatment:—July 11, 1943: 10,000 units of penicillin injected immediately after aspiration of 5 c.cm. of pus: pentothal anaesthesia, as patient was very nervous. Twenty-four hours later, second aspiration: no anaesthesia: 5 c.cm. of sterile pus which inhibited growth of *Staphylococci* to a distance of 4.5 mm. 5,000 units again injected. Result:—Abscess pointed 2 days after starting treatment. Discharged profusely and healed rapidly. Patient was afebrile in 3 days; home in 6 days.

Case 4.—Aged 25. Breast abscess following lactation. Child 3½ weeks old. Breast had been uncomfortable for 2 weeks and a lump had gradually appeared. Four days before admission the lump looked yellow, and the whole breast was painful. Two days later the abscess burst; the pain got worse, and on admission was radiating to the axilla and the arm. Treatment:—Aug. 10, 1943: 6 c.cm. of pus aspirated from the abscess and 10,000 units of penicillin injected. Aug. 12: 8 c.cm. of pus aspirated and 10,000 units of penicillin injected. 9 mm. inhibition. Aug. 13: Under local anaesthesia incision of abscess and drainage of 10 c.cm. of pus. This pus produced an 8-mm. zone of inhibition, and on a blood-agar plate grew only 8 colonies of *Staph. aureus*. Aug. 27: Breast-feeding discontinued. Aug. 31: Under general anaesthesia—incision and drainage of a large retromammary abscess. The pus from this gave a profuse growth of *Staph. aureus* on blood agar, and failed to produce any zone of inhibition. Sept. 12: Wound healing well. Sept. 14: Breast healed; patient discharged. Result:—The patient was febrile until the retromammary abscess was drained on Aug. 31, after 23 days in hospital, and was discharged after 37 days in hospital. Local treatment and the effort to maintain breast-feeding were a failure.

Case 5.—Aged 19. Breast abscess after ceasing to feed baby 6 weeks old. Lump in breast noticed for 3 weeks; increased recently. Abscess involving about one-quarter of breast. Treatment:—July 11, 1943: Under local anaesthesia 3 c.cm. of pus aspirated and 4,000 units of penicillin injected. Forty-eight hours later, 3 c.cm. of pus aspirated, which was sterile and gave a 1-mm. zone of inhibition. 6,000 units again injected. Result:—Three days after onset of treatment abscess pointed and discharged. Patient was afebrile on third day and home on sixth.

Case 6.—Aged 22. Breast abscess following lactation. Child 5 months old. Eight days before admission lump appeared in right breast. Disappeared after three days. Three days before admission lump reappeared and became painful. Treated as an out-patient with kaolin poultices. On admission she had a breast abscess 2½ in. in diameter above the right nipple. Treatment:—Nov. 10, 1943: Aspiration of 10 c.cm. pus; 10,000 units penicillin injected. Nov. 12: Aspiration of 10 c.cm. pus (this pus inhibited standard staphylococci to 11 mm.); 8,000 units injected. Nov. 14: Aspiration of 10 c.cm. pus; 7,000 units injected. Nov. 16: Aspiration of 7 c.cm. pus (this pus inhibited standard staphylococci to 6 mm.); 10,000 units injected. Nov. 18: Aspiration of 4 c.cm. pus. Nov. 20: Cured. Result:—The patient was 9 days in hospital, and afebrile on the third day after starting treatment.

Case 7.—Blind primipara aged 27. Had staphylococcal paronychia at delivery, Sept. 25, 1943. Early in puerperium marked breast engorgement, which went on rapidly to development of bilateral breast abscesses involving most of both breasts. Oct. 14: Aspiration, and penicillin replacement under pentothal. 60 c.cm. pus right—15 c.cm. pus left; 15,000 units of penicillin to each side. Oct. 16: Right, 15 c.cm. pus; 16,000 units of penicillin. Left, 4 c.cm. pus; 8,000 units. Oct. 18: Right, 50 c.cm. pus; 8,000 units. Left, 30 c.cm. pus; 6,000 units. Both breasts then broke down and freely drained through a small hole at the site of aspiration. The right rapidly resolved, and cleared up entirely. She was allowed home on Nov. 14 with sinus discharging in left breast. This had not cleared up by Dec. 24, so she was readmitted and the sinus opened up under anaesthesia, with removal of sloughs. Result:—On Jan. 20, 1944, after three months, the right breast texture was normal, the left still slightly indurated.

Case 8.—Para-5 aged 39. Had had breast abscesses after third and fourth children; also small areolar abscess in this pregnancy. Always same breast affected. On tenth day of puerperium admitted with segmental mastitis. 3 c.cm. of penicillin injected under local anaesthesia into affected area. Increased tension caused consider-

ble pain, but breast improved for a few days, only to develop a large abscess, which was incised on Nov. 28, with removal of 80 c.cm. of pus; 8,000 units were left in drainage wound. Abscess occluded, and required counter-drainage on Dec. 2, after which she made good recovery. Home after 23 days in hospital.

The patient should not have been encouraged to feed from a breast deformed by past infection and incisions. Prophylactic penicillin found impracticable, and useless locally. Incision was resorted to in order to secure efficient drainage of a deep-seated abscess.

**Case 9.**—Aged 23. Breast abscess after lactation. Child 3 weeks old. Breast-feeding stopped, as supply insufficient. Patient admitted with abscess involving two-thirds of breast that had been developing over a period of three weeks. A small superficial abscess had been treated by surgical drainage a fortnight before. Considerable induration of the deeper tissues of the breast was noticed at the time. **Treatment:**—On July 17, 1943, the patient came under our care. On the 18th 5 c.cm. of pus was aspirated under local anaesthesia and 15,000 units of penicillin were injected. Twenty-four hours later there was free spontaneous drainage at site of the old incision—pus inhibiting standard staphylococcus to 3 mm. Twenty-four hours later 6,000 units injected, and three days later 8,000 units into indurated area. **Result:**—The patient was 10 days in hospital—afebrile after 7 days.

**Case 10.**—Aged 29. Breast abscess complicating scabies, which she had had for some weeks. Induration developed in the breast about a week previously. When seen she had an intramammary abscess involving two-thirds of the breast. **Treatment:**—20 c.cm. of pus aspirated under local anaesthetic and 15,000 units of penicillin replaced. Forty-eight hours later 4 c.cm. of pus aspirated with difficulty; this inhibited a growth of staphylococci 11.5 mm. 15,000 units replaced. Forty-eight hours after second injection abscess further localized and pointing on the surface. Incision and drainage done under pentothal; 4 to 5 oz. of pus evacuated. This pus inhibited standard staphylococcus to 5 mm. There was rapid resolution after efficient drainage. **Result:**—Patient was afebrile 7 days from onset of treatment and returned home in 12 days.

**Case 11.**—Aged 35. Seen in post-natal clinic at 10 weeks, with slight induration in right areola. One week later (Oct. 18, 1943) there was a small superficial abscess: 1 c.cm. of pus aspirated; 4,000 units of penicillin injected. Oct. 20: 1 c.cm. of pus aspirated; 3,000 units injected. Breast-feeding continued. The breast settled down, and she was allowed home on Oct. 22. She returned on Oct. 26 with mastitis involving whole breast which developed overnight. Breast-feeding abandoned. The abscess was incised and drained on Oct. 28; no penicillin was used. The breast slowly resolved, the patient being very ill for a fortnight, and, as a sinus persisted, penicillin was injected down it. On Nov. 22 and 23, 8,000 units; on Nov. 25, 2,000 units were given, but no improvement was noticed, and on the 26th the sinus was explored under general anaesthesia and a slough  $2\frac{1}{2}$  by  $1\frac{1}{2}$  in. removed. The wound was drained, and 8,000 units of penicillin injected down the tube. The breast rapidly resolved, and was healed by Dec. 1.

In this case an attempt to maintain breast-feeding in presence of breast abscess was a failure: the inefficiency of local aspiration treatment if there is a slough in the depth of the abscess is also illustrated.

**Case 12.**—Aged 22. Breast abscess following lactation. Child 7 weeks old. Eight days before admission painless lump in left breast. Three days later lump became painful and red, and was treated with kaolin poultices and hot bathing. On admission she had a fluctuating breast abscess 3 by  $2\frac{1}{2}$  in. on the outer aspect of the left breast. Nov. 12, 1943: Under local anaesthesia 9 c.cm. of pus aspirated and 10,000 units of penicillin injected. Nov. 14: Several discharging sinuses on under surface of abscess; induration less; 6,000 units injected at site of original injection. Nov. 20: Sinuses beginning to heal; no discharge or induration. **Result:**—The patient was 7 days in hospital, and afebrile the day after the first injection of penicillin.

**Case 13.**—Aged 35. Developed a segmental mastitis when her baby was 8 weeks old. Baby kept at breast and condition resolved with local treatment, to recur one week later with development of small peripheral abscess. Nov. 14, 1943: Aspiration 1 c.cm. pus; 4,000 units penicillin injected. Nov. 16: Aspiration 1 c.cm. pus; 4,000 units injected. Nov. 18: Aspiration nil; 4,000 units injected. **Result:**—The abscess discharged spontaneously; patient returned home on Nov. 23 with breast healed and lactation still well established.

**Case 14.**—Aged 30. Breast abscess following weaning at 9 months; case first seen with segmental mastitis on Oct. 27, 1943. Stilboestrol and local heat given. Six days later afebrile, but local abscess: 10 c.cm. of pus aspirated; 20,000 units of penicillin injected. Nov. 7: Admitted for aspiration-replacement treatment; doses were 20,000, 8,000, 8,000, and 8,000 units, given on Nov. 7, 9, 11, and 13 respectively. **Result:**—Condition underwent slow resolu-

tion without breaking down. There was still slight induration Nov. 20.

**Case 15.**—Para-7 aged 45, first admitted on fourteenth day puerperium with mastitis, which resolved with local treatment, abandoning of breast-feeding. Patient went home after 7 days return with abscess. Jan. 13, 1944: Aspiration 3 c.cm. pus; 4 units penicillin. Jan. 15: Aspiration 5 c.cm. pus; 4,000 units. **Result:**—Spontaneous discharge from aspiration site, with satisfactory resolution.

### Comment

These cases fall into three groups. In 5 cases surgical drainage was necessary, and conservative treatment may be said to have failed. In 7 cases spontaneous drainage occurred either at a puncture site or elsewhere, and in only 3 did the abscess remain closed and resolve slowly with no evacuation of its contents except by aspiration. On the other hand, the cases in both the second and third groups required no operative or anaesthetic, and their recovery was on the whole more rapid than is usual with simple drainage.

It is possible that some other method of local treatment may give better results, and, in view of the fact that aspiration sometimes cannot sufficiently evacuate the contents of the abscess, surgical drainage followed by instillation of penicillin solution through an indwelling catheter is being used in a further series. When larger supplies of penicillin become available a trial should be made of systemic treatment at an earlier stage in order to control the inflammatory process before suppuration has occurred, and so permit the continuation of breast-feeding.

## PENICILLIN IN TREATMENT OF CERTAIN DISEASES OF THE SKIN

BY

I. A. ROXBURGH, M.B., B.Ch.

RONALD V. CHRISTIE, M.D., D.Sc., F.R.C.P.

AND

A. C. ROXBURGH, M.D., F.R.C.P.

The unique properties of penicillin as an antiseptic suggested that it might be of value in the treatment of some diseases of the skin. This seemed a suitable field of inquiry for two further reasons: first, the probability, from bacteriological principles, of a good response from some of the pyogenic infections of the skin; and, secondly, the likelihood of comparatively small amounts of penicillin being required.

The present survey comprises 75 cases. These were all in-patients, and it was thus possible closely to supervise the treatment, which was by local application alone. All cases were investigated bacteriologically before treatment was begun, and the penicillin-sensitivity of the organisms present was qualitatively determined. Unless otherwise stated, the bacterial flora described as being present was, to a greater or lesser degree, penicillin-sensitive. The number of units used in each case should be regarded as only approximate, and was often related to the extent of the disease rather than to its severity. The word "cure" is used in this paper to imply complete healing of lesions at some particular time. It does not necessarily mean a permanent eradication of the disease.

### Sycosis Barbae (15 Cases)

This was chosen as a suitable disease for preliminary investigation because it so often fails to respond adequately to other methods of therapy. Crusts, if present, were removed before penicillin was applied, and shaving was discouraged, especially in the early stages of treatment. Penicillin was usually applied as an ointment containing 400 units of calcium or sodium penicillin per gramme of base, the latter being a mixture of equal parts of lanette wax S.X., petroleum jelly and water. In a few cases the strength used was 200 units per g., and in some the base contained 50% of water with 25% of each of the other ingredients. It was felt that if the base contained 50% of water it might be of more suitable consistency, but this did not prove to be so. In other cases solutions of penicillin were used.

**Case 1.**—M., aged 31. Duration of disease 11 years. X rays, vaccines, sulphonamides, quinoline, and other local applications had produced only temporary improvement. Numerous small pustules over whole beard area. Organisms, *Staph. aureus*. 12,800 units (calcium salt in lanette base, 200 units per g.) in 16 days. Daily applications to worse side (left) only. Right side similarly treated with lanette base without penicillin. Result was apparent cure on left, very slight improvement on right. Followed by 16,800 units to both sides in 18 days, with apparent cure. A few pustules reappeared 2 weeks later. Three weeks after end of treatment he was sent a further 12,000 units, which he applied during the ensuing 5 weeks. This produced complete cure, which has now lasted 22 weeks.

**Case 2.**—M., aged 46. Duration 6 years. Temporary improvement only with x rays, vaccines, sulphonamides, quinoline, and brilliant green. Extensive crusting of whole beard area and neck and eyebrows. Organisms, *Staph. aureus*. 17,000 units (calcium salt in lanette base (50% water), 200 units per g.) in 17 days. Daily applications to worse side only (left). Base only to right side. Marked improvement on left side; rather less marked improvement on right. Then 9,000 units to both sides in 7 days. Both sides cured. A very mild relapse occurred 5 weeks later. This was not treated. Sixteen weeks after treatment ended he was seen to have a very few small spots, but rather a severe blepharitis. This was cured by the application of 12,000 units in 2 weeks; but by then a few pustules had appeared on the face. These were cured by a further 12,000 units, and the cure has now lasted 9 weeks.

**Case 3.**—M., aged 49. Duration 7 years. Temporary improvement only with x rays, sulphonamides, and numerous local applications. Slight crusting. Organisms, *Staph. aureus*. 4,100 units (calcium salt in lanette base (50% water), 200 units per g.) in 20 days. Daily application to worse side only (left). Result: great improvement on left side. Then 5,600 units to both sides in 14 days. Both sides cured. Slight relapse 10 days later. Five weeks after stopping treatment he was given a further 12,000 units, and responded well. Now cured for 14 weeks.

**Case 4.**—M., aged 41. Duration 2 years. Temporary improvement only with x rays, quinoline, and other local applications. Lesions most prominent on cheeks and upper lip. Organisms, *Staph. aureus* and *Strep. pyogenes*. 8,000 units (calcium salt in lanette base (50% water), 400 units per g.) in 8 days. Daily applications to left side only. Great improvement. Then 34,000 units to both sides in 17 days. Both sides cured. No relapse after 19 weeks.

**Case 5.**—M., aged 29. Duration 3 years. Temporary improvement only with x rays, sulphonamides, and other local applications. Infection confined to upper lip and eyelids. Organisms, *Staph. aureus*. 4,600 units in 23 days. Calcium salt in lanette base. 200 units per g., applied daily to upper lip. Solution of calcium salt (500 units per c.c.m.) as eye drops (2 drops into each eye 2-hourly by day) and ointment applied to lids at night, for 5 days. Blepharitis cured, upper lip almost so. Used a further 3,000 units during next 2½ weeks, and was then seen to be cured. Slight return of crusting on the upper lip 15 weeks later. When this had been present one week he was given quinoline emulsion for the next week, and during the subsequent 2 weeks used a further 12,000 units of penicillin. He was then seen to have relapsed almost completely, with some return of the blepharitis. Ointment appeared to be irritating the lesion.

**Case 6.**—M., aged 22. Duration 4 months. Temporary improvement with x rays, ultra-violet light, sulphonamides, brilliant green, crystal violet, etc. Scattered lesions over whole beard area. Organisms, *Staph. aureus*. 7,500 units (sodium salt in lanette base, 400 units per g.) in 30 days. Applications daily for 11 days, then twice daily. Complete cure: has now lasted 16 weeks.

**Case 7.**—M., aged 22. Duration 3 years. Temporary improvement only with local applications and x rays. Lesions extensive; blepharitis present. Complicated by seborrhoeic dermatitis. Organisms, *Staph. aureus*. 11,340 units (sodium salt in lanette base, 400 units per g.) in 21 days (applied twice daily). Improvement till 11th day, then complete relapse, so that face was "worse than ever before." Further slight improvement just before treatment was stopped. Culture from a pustule at this stage showed that the organism had increased its resistance to penicillin. Given x rays (50 r twice) with some improvement. Two weeks later a second course, using solution of calcium penicillin (1,000 units per c.c.m.), was started. 38,410 units in 15 days. Face sprayed 4 times daily (right side only for first 7 days). After this both sides seemed to be cured. Solution then applied to eyes (2 drops into each, 4 times daily), 22,470 units being given in 21 days. Blepharitis cured a few days before treatment was stopped. Face began to relapse only a few days after treatment to the eyes was finished. After 2 weeks there was a return of the blepharitis. Condition was stationary for the next 6 weeks under treatment with pyrogallol in zinc cream.

**Case 8.**—M., aged 40. Duration 2½ years. No response to quinoline, nasal operations, x rays, or sulphonamides. Infection of

skin localized to upper lip and eyelids, but chronic purulent nasal discharge present. Organisms, *Staph. aureus* and *Strep. pyogenes*. 11,970 units (sodium salt in lanette base, 400 units per g.) in 21 days (applied twice daily). Gradual improvement for 15 days, then complete relapse. Organisms showed some increase in resistance to penicillin. Quinoline emulsion and x rays produced some improvement during next 2 weeks. Second course then started. 118,750 units (solution of calcium salt, 1,000 units per c.c.m.) in 19 days. Solution sprayed on to upper lip and up nose 4 times daily. Improvement for 11 days, then complete relapse; the solution appeared only to irritate the lesions.

**Case 9.**—M., aged 38. Duration 2½ years. Sulphonamides and local applications ineffective. Scattered lesions, associated with seborrhoeic dermatitis. Organisms, *Staph. aureus*. 5,600 units (sodium salt in lanette base, 400 units per g.) in 8 days (applied twice daily). Complete cure. Relapse began after 2 weeks and became severe after 4 weeks. Treated by 49,950 units (solution of calcium salt, 1,000 units per c.c.m.) in 15 days. Sprayed on twice daily. Complete cure. Relapse after 5 days. Seen 6 weeks later, the condition was not severe, although he had had no further treatment.

**Case 10.**—M., aged 31. Duration 3 years. Only temporary improvement with x rays and local applications. Lesions worst on chin and forehead. Some crusting. Organisms, *Staph. aureus*. 17,625 units (calcium salt solution, 1,000 units per c.c.m., and in lanette base, 400 units per g.) in 14 days. Sprayed 4 times daily for 3 days, then twice daily. Ointment only for last 2 days. Almost cured. Cure completed after application of a further 6,000 units in 2 weeks. Began to relapse a few days later. During 2nd and 3rd weeks after start of relapse he used another 12,000 units, but the ointment only irritated his skin, and no progress was made.

**Case 11.**—M., aged 32. Duration 3 months. Sulphonamides and other local applications ineffective. Organisms, *Staph. aureus*. 24,970 units (sodium salt in lanette base, 400 units per g.) in 27 days (applied twice daily) produced complete cure. Relapsed a few days later. Eight weeks later his condition was not severe, though other methods of treatment had been employed in the interval.

**Case 12.**—M., aged 47. Duration 2½ years. All local applications ineffective. Lesions scattered over beard area, but mostly in midline. Organisms, *Staph. aureus*. 139,860 units (solution of calcium salt, 1,000 units per c.c.m.) in 28 days. Sprayed thrice daily. Complete cure. There was minimal improvement for the first 5 days, but cure was almost complete after 18 days.

**Case 13.**—M., aged 27. Duration 5 years. Only temporary improvement with numerous local applications, 2% crystal violet being the most useful. Severe crusting of upper lip; eyelids and left eyebrow also affected. Chronic sinusitis. Organisms, *Staph. aureus*. 67,190 units (solution of calcium salt, 1,000 units per c.c.m.) in 15 days. Sprayed on thrice daily. There was a gradual but steady improvement. Had to be discharged for domestic reasons, and was given 12,000 units as ointment with which to continue treatment.

**Case 14.**—M., aged 23. Duration 1½ years. Recent exacerbation. Temporary improvement with quinoline emulsion. Generalized rash all over beard area: some impetiginous lesions also. Organisms, *Staph. aureus*. 50,000 units in 15 days. Solution of calcium salt sprayed on thrice daily. Complete cure, which has now lasted one week.

**Case 15.**—M., aged 21. Duration several months. Only temporary improvement with quinoline emulsion. Generalized rash, but predominant on chin. A few impetiginous lesions present. Organisms, *Staph. aureus* and *Strep. pyogenes*. 40,920 units in 12 days. Solution of calcium salt sprayed on thrice daily. Complete cure.

#### Commentary

In judging these results it is necessary to remember that most of the cases were chosen for the very reason that they were of long duration or had notably failed to respond to ordinary methods of treatment.

Analysis of results shows that: (a) Five cases (Nos. 4, 6, 12, 14, 15) were initially cured and have remained so. These cures have lasted for periods up to 19 weeks. (b) Three cases (Nos. 1, 2, 3), though initially cured, relapsed after periods varying from 10 days to 5 weeks. Their relapses were cured, and cures have now lasted for periods varying from 9 to 22 weeks. (c) Five cases (Nos. 5, 7, 9, 10, 11), though initially cured, relapsed after periods varying from a few days to 15 weeks, and their relapse remains uncured. (d) One case (No. 8) was never cured. In one case (No. 13) treatment is still in progress.

The remarkable initial response in the first 6 cases which we treated was perhaps unfortunate, as it led to false confidence in the method of application. It became clear subsequently that the ointment used could in some cases lead to irritation of the skin, though which constituent of the

ointment was responsible is not at present clear. The comparative impurity of present supplies of penicillin must be remembered as a possible cause. Further investigations on methods of application are clearly indicated, but even if the ideal method is found it still appears that recurrences in some cases may be frequent. The tendency of cases of sycosis barbae to relapse after apparent cure is well known, and there is no reason to suppose that penicillin can abolish this inherent tendency. The most to be expected of penicillin is, that it may cure established infection or, if applied prophylactically, prevent reinfection. Established infection was indeed cured, though sometimes only temporarily, in all but one of this series. In the exception (Case 8), failure was probably due to a continual reinfection from the nasal discharge. It may be noted here, in connexion with associated disease, that all three patients who also suffered from seborrhoeic dermatitis relapsed within 14 days of cure.

The significance of the increase in resistance to penicillin displayed by the organisms in Cases 7 and 8 is doubtful; this also requires further elucidation. The use of solution is not recommended except perhaps in cases irritated by the ointment, as it tends to be extravagant of penicillin and does not appear to produce final cure any more quickly. There is sometimes, however, a more dramatic response during the first few days. Twice-daily spraying is probably adequate. The solution seemed to irritate the skin in Case 8.

Treatment should in all cases be continued for a few days after apparent cure; in our cases penicillin was probably stopped earlier than was desirable, owing to the need for economy in its use. When it becomes freely available it should be possible to start treatment at the first signs of a relapse or even to use penicillin prophylactically.

This series is a small one, and further experience may show that we have been unduly fortunate in our results. Even if this proves to be the case, it is clear that, while penicillin can by no means be relied upon to produce a lasting cure in all cases of sycosis barbae, it can in individual cases produce results unobtainable by any other means. If only for this reason, it has a definite place in the treatment of the disease.

#### Impetigo (12 Cases)

Some of these were primary impetigo and others were secondary to disease such as scabies. All were treated by removal of crusts followed by local application of sodium or calcium penicillin in the lanette wax and petroleum jelly base, 400 units per g.

**Case 1.**—M., aged 7. Duration 7 days. Upper lip, cheeks, and backs of hands predominantly affected. Organisms, *Strep. pyogenes*. 1,800 units in 9 daily applications. Single lesions healed in 2 to 3 days; cure complete in 9 days.

**Case 2.**—M., aged 19. Duration 20 days. Extensive crusting of face, ears, arms, buttocks, and thighs. Organisms, *Strep. pyogenes* and *Staph. aureus*. 8,505 units in 21 daily applications. Only one area was treated at a time, so final cure was delayed; individual areas were cured after 4 to 6 days' treatment.

**Case 3.**—F., aged 4. Duration 11 months. Associated with seborrhoeic dermatitis, and affecting scalp and ears. Organisms, *Strep. pyogenes* and *Staph. aureus*. 18,900 units in 21 daily applications. Rapid improvement for 10 days; condition then became stationary. The improvement coincided with elimination of the secondary infection, the seborrhoeic dermatitis being unaffected by further treatment.

**Case 4.**—M., aged 1. Duration 5 weeks. Associated with scabies, and affecting face and ears. Organisms, *Strep. pyogenes* and *Staph. aureus*. 2,800 units in 11 days (applied twice daily). Single lesions healed in 3 to 4 days; cure complete in 11 days.

**Case 5.**—M., aged 10. Duration 10 days. Face only affected. Organisms, non-haemolytic streptococci and *Staph. aureus*. 3,960 units in 9 days (applied twice daily). Single lesions healed in 4 days; cure complete in 9 days.

**Case 6.**—M., aged 4. Duration 12 days. Face, ears, and legs. Organisms, *Strep. pyogenes*. 14,000 units in 8 daily applications. Single lesions healed in 3 days; cure complete in 8 days.

**Case 7.**—F., aged 6 months. Duration 14 days. Associated with seborrhoeic dermatitis and scabies, and affecting scalp, trunk, and limbs. Organisms, *Staph. aureus*. 16,560 units in 6 daily applications. Complete cure of impetigo. Relapsed after 15 days. Cured by application of 7,360 units in 8 days.

**Case 8.**—F., aged 5. Duration 3 weeks. Associated with scabies, and affecting lower limbs. Organisms, *Strep. pyogenes* and *Staph.*

*aureus*. 12,000 units in 8 days (applied twice daily). Single lesion healed in 5 days; complete cure in 8 days.

**Case 9.**—M., aged 37. Duration 12 days. Extensive crusting of face. Organisms, *Staph. aureus*. 24,000 units in 12 daily applications. Great improvement in 5 days; cure complete in 12 days.

**Case 10.**—M., aged 24. Duration 14 days. Scalp, neck, and forearms affected. Organisms, *Staph. aureus*. 11,960 units in 12 days (applied twice daily). Scalp cured in 4 days; other areas require 12 days.

**Case 11.**—M., aged 27 years. Duration 10 days. Face, scalp, arms. Conjunctivitis and blepharitis. Organisms, *Staph. aureus* and diphtheroids. 8,170 units in 19 daily applications to face, scalp and arms. (Eyes also treated—see "Blepharitis," Case 5.) Almost well in 5 days, but even by the 19th day a few new lesions were appearing.

**Case 12.**—F., aged 3½ months. Duration several weeks. Scalp, face, and hands, affected. Underlying eczema of scalp and face. Organisms, haemolytic streptococci. 24,000 units in 15 daily applications. Impetigo cured in 5 days; 10 days' further treatment had no beneficial effect on the eczema.

#### Commentary

It will be seen that of 12 cases treated 11 were completely cured. The important factor is the time required to produce this result: on an average this was 8 to 9 days. Most of these patients, however, were in a fairly advanced condition when treatment was started, and as ointment was applied only in the immediate neighbourhood of the lesions it was difficult to prevent spread to unaffected areas. Individual lesions under treatment healed in about 4 days.

Minor variations in the routine of treatment do not seem to be of much importance: for instance, one application of ointment a day appears as effective as two. But when penicillin becomes more easily obtainable it may be possible, by spreading it more widely, to prevent formation of new lesions and materially accelerate complete cure.

We consider that penicillin can be more generally relied upon to produce a rapid cure than can quinoline emulsion or sulphonamides, though these drugs may in individual cases be equally successful.

In view of discussions regarding the bacteriology of impetigo it is worth noting that in these 12 cases the infecting organisms were: in 3 cases, *Strep. pyogenes* alone; in 3 cases, *Staph. aureus* alone; in 4 cases, *Staph. aureus* and *Strep. pyogenes*; in 1 case, *Staph. aureus* and non-haemolytic streptococci; in 1 case, *Staph. aureus* and diphtheroids.

#### Eczema (9 Cases)

For the most part the patients treated were resistant cases of chronic eczema in which it seemed that elimination of secondary infection might aid recovery. All were treated with sodium or calcium penicillin in the lanette wax and petroleum jelly base, 400 units per g.

**Case 1.**—M., aged 27. Duration several weeks. Large raw areas on hands, forearms, face, and ears, resistant to all previous treatments. Organisms, *Staph. aureus*. 29,070 units in 21 daily applications. Notable improvement, patient being left with a residual dry eczema, which responded to ordinary methods of treatment.

**Case 2.**—F., aged 67. Duration 10 days. Severe weeping eczema of wrists and hands with purulent blisters. Organisms, *Strep. pyogenes* and *Staph. aureus*. 16,000 units in 13 days to right hand only (applied twice daily). Left side treated with zinc cream. Right hand cured after 11 days, left after 13 days.

**Case 3.**—M., aged 35. Duration 6 months. Dry scaly eczema of face, neck, and ears with fissuring. Organisms, *Strep. pyogenes* and *Staph. aureus*. 39,200 units in 7 daily applications to right side only. Great improvement after 3 days, whereupon base alone was applied to left side. This resulted in similar but less rapid improvement. Subsequent application of base without penicillin to both sides effected cure, but relapse occurred a few weeks later.

**Case 4.**—M., aged 20. Duration 4 days. Vesicular eczema of left index, with pustules on rest of hand. Organisms, *Staph. aureus*. 24,000 units in 10 daily applications. No improvement in eczema.

**Case 5.**—M., aged 23. Duration 16 years. Generalized eczema with fissures. Organisms, *Staph. aureus* and another Gram-positive coccus. 36,000 units in 20 days (applied twice daily) to face and neck only. Fissures healed. Otherwise unaffected.

**Case 6.**—M., aged 2½. Generalized infantile eczema dating from birth. Organisms, *Strep. pyogenes* and *Staph. aureus*. 30,100 units in 22 days (applied twice daily). No change for 5 days; thereafter

steady improvement. Began to relapse 2 to 3 days after treatment stopped.

Case 7.—M., aged 25. Duration 3 weeks. Face predominantly affected. Sterile on culture. 6,000 units in 15 daily applications. Cured.

Case 8.—M., aged 8 months. Duration 4½ months. Scalp and left cubital fossa. Organisms, *Strep. pyogenes* and *Staph. aureus*. 12,040 units in 14 daily applications. Improved for 5 days, then relapsed. (Prevention of scratching was very difficult.)

Case 9.—M., aged 58. Duration 8 months. Large raw weeping patch below the knee. Organisms, *Staph. aureus* and *Strep. pyogenes*. 71,810 units in 22 days (applied twice daily). Healed; only a residual redness persisted.

#### Commentary

Cases 3 and 7 suggest that such improvements as occurred in this series were possibly due to the lanette base rather than to penicillin. There is little doubt, however, that in Cases 1 and 9 the dramatic improvement was the result of controlling the infection, and the limited success in Cases 5 and 6 is in agreement with this. Penicillin should be worthy of trial in cases of eczema with evidence of secondary infection.

#### Blepharitis (8 Cases)

This condition has been mentioned in connexion with sycosis barbae; the cases now to be described were, however, not accompanied by sycosis. They were treated by application of sodium salt in lanette wax and petroleum jelly base, 400 units per g., to the lids, or by instillation of solution of sodium or calcium penicillin into the eye. All cases were bilateral. The results of treatment are in general agreement with those obtained by Florey and Florey (1943).

Case 1.—F., aged 3. Duration 5 months. Eyebrows also infected. Organisms, *Neisseria catarrhalis*, *Strep. pyogenes*, and *Staph. aureus*. 1,640 units (ointment) in twice-daily applications for 3 days. Cured. Relapsed after 10 days. 2,870 units in twice-daily applications for 7 days. Cured. Relapse after 3 weeks. *Staph. aureus* found to be less sensitive than previously. 6,000 units in daily applications for 15 days. Cured in 10 days. Slight relapse about 3 weeks later. When seen 8 weeks after treatment was stopped the right eye showed a mild blepharitis and the left appeared cured. The only treatment had been local application of petroleum jelly.

Case 2.—M., aged 35. Duration 28 years. Organisms, *Staph. aureus*. 5,800 units (sodium salt in saline, 500 units per c.c.m.) in 10 days. Two drops 2-hourly by day into left eye only, for 6 days. Great improvement in left eye. Then both sides treated. Cure in 10 days. Relapsed after a few weeks.

Case 3.—F., aged 30. Duration 2½ years. Seborrhoeic dermatitis present. Organisms, *M. tetragenus* and *Staph. aureus*. 1,400 units in daily applications for 7 days. Cured.

Case 4.—M., aged 22. Duration 3½ years. Bilateral conjunctivitis. Organisms, *Staph. aureus*. 8,920 units in 12 days. Two drops of sodium salt solution in saline (500 units per c.c.m.) into each eye 2-hourly by day. Ointment also applied to lids nightly, but discontinued owing to intense irritation produced. Thereafter solution was applied to lids on a swab instead. Complete cure, which has now lasted 11 weeks.

Case 5.—M., aged 27. Duration 9 days. Impetigo and conjunctivitis also present. Organisms, *Staph. aureus* and diphtheroids. 3,800 units (ointment) in daily applications over 19 days. Cured. (Impetigo also treated—see "Impetigo," Case 11.)

Case 6.—M., aged 26. Duration 14 years. Organisms, *Staph. aureus*. 8,000 units (solution of calcium salt, 1,000 units per c.c.m.)—2 drops 2-hourly by day into each eye in 5 days. Cured. Has now remained cured for 9 weeks.

Case 7.—F., aged 43. Duration 3 weeks. Associated with pemphigus vulgaris. Organisms, *Staph. aureus*. 2,340 units in twice-daily applications for 5 days (ointment). Cured. Relapsed after 10 days. 6,500 units in 13 days. Cured. Seven weeks later there was only a slight residual redness of the lids (but the pemphigus had also improved).

Case 8.—M., aged 32. Duration 2 weeks. Organisms, *Staph. aureus*. 3,150 units in twice-daily applications of ointment over 9 days. Cured. Slight relapse 6 days later. 2,800 units applied in 8 days. Cured. No relapse when seen 7 days later.

#### Commentary

Previous experience with conjunctivitis has led us to expect that solution of sodium salt in saline (500 units per c.c.m.) would be less irritant to the eye when used as drops than aqueous solution of calcium salt (1,000 units per c.c.m.). Patient No. 6, however, did not find the latter uncomfortable, and it seems that individuals vary in their tolerance. The

application of ointment to the lids was not usually productive of any reaction, though in Case 4 it did produce a marked aggravation of the blepharitis.

Blepharitis being generally extremely resistant to treatment, the initial response of these cases is most encouraging. The frequency of relapse is at present a disappointing feature, but when supplies of penicillin are better it may be possible to prevent relapse by, for example, a nightly application of the drops.

#### Otitis Externa (7 Cases)

These cases were treated by sodium penicillin in lanette wax and petroleum jelly base (400 units per g.) or by solution of calcium penicillin (1,000 units per c.c.m.). Where the solution was used, drops were introduced into the external meatus thrice daily, and it was then plugged with cotton-wool or petroleum jelly gauze.

Case 1.—M., aged 45. Bilateral. Duration 7 months. Organisms, *Staph. aureus*, diphtheroids, coliforms, and an unidentified Gram-positive coccus. 36,870 units (solution) in 7 days. After 5 days there was an improvement, and sensitive organisms were no longer present. Before treatment was finished, however, there was a relapse.

Case 2.—M., aged 56. Bilateral. Duration 2 years. Organisms, diphtheroids, coliforms, and *B. proteus*. 89,665 units (solution) in 22 days (twice daily only during final 7 days). Number of sensitive organisms diminished, but there was only improvement—not cure. Nineteen weeks later his improved condition was still being maintained.

Case 3.—M., aged 41. Right side only. Duration 35 years. Organisms, *Staph. aureus*, diphtheroids, and coliforms. 18,765 units in 8 days (solution). No sensitive organisms after second day. Cured in 5 days; relapsed 5 days later.

Case 4.—F., aged 23. Bilateral. Duration 5 months. Organisms, *Staph. aureus* and coliforms. 6,000 units in 22 days (ointment, applied twice daily). Complete cure. Discharged to use another 6,000 units. No relapse reported after 10 weeks.

Case 5.—M., aged 31. Bilateral. Duration 1½ years. Organisms, streptococci, *Staph. aureus*, *B. proteus*, and diphtheroids. 74,000 units in 14 days (solution twice daily only for last 5 days). Clinical cure by 5th day, but bacteriology still unaltered by 10th day.

Case 6.—M., aged 39. Bilateral. Duration 14 months. Organisms, *Staph. aureus*, *Strep. faecalis*, diphtheroids, and coliforms. 3,000 units in 15 daily applications of ointment. Cured. Relapsed 17 days later. A more resistant collection of organisms found. 6,000 units in 22 daily applications. Improvement but no cure.

Case 7.—M., aged 25. Bilateral. Duration 3 weeks. Organisms, *Staph. aureus* and coliforms. 6,000 units in 15 daily applications of ointment. Cured.

#### Commentary

These infections have all been mixed; and without exception part of each flora has been insensitive to penicillin. The incidence of incomplete cures and early relapses is therefore not surprising. Ointment is a simpler and more economical method of treatment than the solution, and appears to be equally effective.

#### Boils (5 Cases)

These were treated with sodium penicillin in lanette base, 400 units per g.

Case 1.—M., aged 31. Recurrent furunculosis of buttocks of 13 months' duration. Organisms, coagulase-negative *Staph. albus*. 21,000 units in 12 daily applications effected cure before end of treatment. Used a further 12,000 units after discharge. No relapse 12 weeks later.

Case 2.—M., aged 10. Boils on back of neck of 3 weeks' duration. Organisms, *Staph. aureus*. 4,080 units in 14 days (applied twice daily). Slight improvement only.

Case 3.—M., aged 65. Axillae chiefly affected. Duration 2 months. Organisms, *Staph. aureus*. 3,500 units in 2 daily applications. Cure, lasting now 11 weeks.

Case 4.—M., aged 15. Neck and chin. Duration 2 days. Organisms, coagulase-negative staphylococci. 6,090 units in 15 days (applied twice daily). Cured.

Case 5.—M., aged 24. Large discharging boils on buttocks. Duration uncertain (mentally defective). Organisms, *Strep. pyogenes* and *Staph. aureus*. 24,000 units in 15 daily applications. Healed. No new lesions.

#### Commentary

Patient No. 3, the only apparently spectacular cure, was recovering from existing lesions when treatment was started; the fact that no further lesions have appeared may be due to penicillin. These cases suggest that penicillin may possibly

be useful in stopping a series of recurrent boils. Probably the solution would have been more effective than the ointment, although more extravagant. Penicillin applied externally appeared to have no effect whatever on the evolution of an individual boil.

### Acne (3 Cases)

*Case 1.*—M., aged 23. Pustular acne of face, neck, chest, and back of 8 years' duration. Culture sterile. 15,000 units (sodium salt in lanette base, 400 units per g.) in 12 days (applied twice daily). Very slight improvement.

*Case 2.*—M., aged 22. Pustular acne of face, back, and chest. Duration 6 years. Organisms, *Staph. aureus*. 37,060 units (sodium salt in lanette base, 400 units per g.) in 34 daily applications to left side of back only. Improvement for first 10 days; thereafter i.s.q.

*Case 3.*—M., aged 40. Acne conglobata of 5 years' duration. Arms, chest, and back extensively affected. Organisms, *Staph. aureus*. 235,320 units in 29 days. Solution of calcium salt (1,000 units per c.cm.) was sprayed on 4 times daily. Cured. Gradual relapse began after 7 days.

### Commentary

Since greasy creams are in any event unsuitable for application to cases of acne, and since treatment in Case 3 was temporarily successful, it might have been better to use solution in Cases 1 and 2 also. The method is, however, extravagant. The value of penicillin in this condition remains uncertain. The acne bacillus is resistant to penicillin, and the response of the disease to treatment will depend presumably on the extent to which staphylococci are accountable for the suppuration in each particular case.

### Miscellaneous

The following results are recorded for the sake of completeness, but it is not possible to draw any conclusions of value from them. The ointment was used unless otherwise stated.

Two cases of generalized seborrhoeic dermatitis were treated: one failed to respond with ointment, but recovered temporarily when solution was sprayed on to affected areas; the other responded to ointment only in areas where secondary infection was marked. A third case, in which the disease was confined to the scalp, cleared up well when treated with ointment. (Staphylococcal secondary infection was present.) One small carbuncle which was discharging healed in 12 days under treatment with ointment. A case of Bockhart's impetigo accompanied by boils was improved, but the boils were hardly affected. A case of dermatitis repens (Crocker) failed to respond. Four cases of chronic ulceration of the lower limb of uncertain aetiology were all improved. Two cases of varicose ulceration were treated; one patient failed to respond, and the other, who was suffering from varicose eczema as well, was greatly benefited. One case of psoriasis, one case of herpes labialis, and one case of pemphigus vulgaris were unaffected.

### Summary

The treatment of 75 cases of skin disease by local application of penicillin is described.

The drug is of obvious value in sycosis barbae, impetigo, and blepharitis. It is also effective in some cases of chronic eczema with secondary infection and in some cases of otitis externa.

### REFERENCE

*The World's Children* (published by the Save the Children Fund, 20, Gordon Square, W.C.1; 6d.) now reverts to its former character as a "journal of child care and protection considered from an international viewpoint." The more domestic news of the Fund, in whose interest the magazine is published, is relegated to an appended "Current Chronicle." International interests include an article on the United Nations Relief and Rehabilitation Administration, by Gladys Skelton. Sylvia Thompson expands her suggestion that the best war memorial would be the interchange of young people between the different countries to help to promote world understanding; and Lillian de Lissa, describing wartime care of children in the United States, stresses the eagerness of the Americans to profit by Great Britain's wartime experience in the nursery schools field. Elsa Castendyck discusses the causes of juvenile delinquency. The German system of food rationing is revealed in a table showing the provision of essential foods for various age groups of children. The effects of the war on the rising generation in Europe are seen through Swiss eyes by Dr. Georges Thélin of Geneva.

## THE LABORATORY CONTROL OF PENICILLIN TREATMENT

BY

LAWRENCE P. GARROD, M.D., F.R.C.P.

The bacteriological laboratory has very heavy duties in connexion with the clinical use of penicillin, and where cases are being treated it is strongly advisable that so much in the laboratory should be enabled to devote almost whole time to the necessary work. This work falls into three main categories: the preparation of solutions, etc., bacteriological diagnosis, and observation of the results of treatment by various *in vitro* tests.

The methods of preparing penicillin for clinical use employed in this and other present research centres are described in a forthcoming M.R.C. Memorandum, and cannot be given in detail here. Penicillin is supplied in the form of powder or tablets; solutions of various strengths have to be prepared from this, and sometimes diluted powders or creams. In the performance of this work two properties of penicillin should be constantly borne in mind. It is a very labile substance, liable easily to lose its activity under adverse conditions. It is also not an ordinary antiseptic, capable of destroying any bacteria with which it may become contaminated; on the contrary, there are many species quite unaffected by it which will not only remain alive in solutions of penicillin but may even decompose them, with consequent loss of activity. These two properties call for high standards of precaution in handling during preparation and for exceptional safeguards during subsequent use.

A refrigerator is the only suitable place to keep solutions and creams before and during use. We have also found it advisable that each patient under local treatment should have his own bottle of solution, owing to the danger of contamination in the ward: this has been known to occur by withdrawing the contents with a syringe and needle or tubing which has already been used for aspirating the lesion. Penicillin can easily become a vehicle of cross-infection, and surplus solution returned after use to the laboratory has occasionally been found grossly turbid owing to the presence of pus and living bacteria.

### Initial Bacteriological Diagnosis

Penicillin is effective only against certain bacteria, and it is therefore necessary to know the nature of the infection before embarking on treatment with any confidence in its result. In characteristic conditions having only one usual microbial cause, such as impetigo and sycosis, this may appear superfluous in routine treatment, but even here it may be advantageous, since it is advisable to know not only the species of micro-organism concerned but the sensitivity of the particular strain to penicillin; in some species, particularly staphylococci, this is variable. An exact but time-consuming method is to isolate the responsible pathogen in pure culture and inoculate broth containing various low concentrations of penicillin to determine the least which will inhibit growth. A much more rapid method, quite satisfactory for most purposes, which furnishes both a species and a sensitivity diagnosis from one primary culture, is Fleming's agar cup method. One or two circular holes are punched in a blood agar plate with a sterile cork-borer, and, after inoculation and spreading, a drop of weak penicillin solution (10 units and 1 unit per c.cm.) is pipetted into each hole. Penicillin diffuses into the surrounding medium, where its concentration varies inversely with distance from the cup; the width of the zone surrounding the cup in which no colonies appear is thus a measure of the sensitivity of the organism. In mixed cultures two zones are often evident—an inner containing no growth, and an outer containing colonies of only one more resistant species. Both for an expeditious diagnosis and for dealing with many cases this method is invaluable. The following observations on the sensitivity of different species have been made by this and other methods.

*Gram-positive Cocci.*—As previously reported by others, we have found occasional strains of otherwise typical *Staph. aureus* abnormally resistant to penicillin. This was sometimes

property of the original culture, but more often it developed during treatment, clearly owing to habituation; there was corresponding failure of clinical progress. No resistant strain of *Strep. pyogenes* or of *Pneumococcus* has been encountered. The widely varying susceptibility originally reported by the Oxford workers for both *Pneumococcus* and *Strep. viridans* is not borne out by our experience; no really resistant strain of either has been found. *Strep. faecalis* (enterococcus), on the other hand, is always highly resistant.

**Mouth Bacteria.**—Observations made mainly in connexion with work described in an earlier paper (p. 517) by Mowlem have led to the conclusion that the great majority of the very numerous bacterial species found in the mouth are penicillin-sensitive. This is of far-reaching practical importance, since it means that infections derived from or connected with the mouth are in general susceptible to penicillin treatment, just as those connected with the bowel are insusceptible owing to the prevalence there of resistant species. The flora of the mouth is highly complex and has been imperfectly studied; the following observations are therefore perforce of an elementary nature. In plates, both aerobic and anaerobic, inoculated with material from osteomyelitis of the jaw, from infected compound fractures of the jaw, and from infected gums, or with saliva, the only organisms ever found markedly resistant to penicillin as judged by the cup method have been *Moraxella albicans*, an occasional *Neisseria*, and *Haemophilus*. Whole groups of bacteria which are thus sensitive in doubtless varying but apparently adequate degrees are aerobic streptococci (including various types of *Strep. viridans*), anaerobic

**Mixed Infections.**—It has sometimes to be decided whether a mixed infection including sensitive and resistant bacteria is suitable for treatment. The latter are usually Gram-negative bacilli, and much appears to depend on whether they are active producers of penicillinase and may thus destroy the penicillin in the lesion. *Proteus* does not produce penicillinase, and combined infections by this organism and staphylococci have been treated successfully in this series; the cocci disappear, and although *Proteus* remains the condition improves, suggesting that the coccus has played the more important part in maintaining the infection. On the other hand, combined infection by a pyogenic coccus and a penicillinase-producing coliform bacillus may be quite unaffected; in one such case, the lesion being a cavity in which solution could be well retained, haemolytic streptococci persisted in undiminished numbers. That the reason for this was the destruction of penicillin by the coliform bacillus in the wound fluid was proved by repeatedly demonstrating that on withdrawal after 24 hours the penicillin content of this fluid was nil.

#### Examinations to Check the Results of Treatment

Swabs or other specimens have been obtained daily, and sometimes at longer intervals later, which were cultivated in order to follow the effect of treatment. When this is successful, immediately scantier growths are succeeded by total sterility. The results obtained in 60 miscellaneous cases treated locally are given in Table I. This includes only wounds (not skin diseases)—cases in which there was a simple infection by staphylococci or haemolytic streptococci, or both—and excludes

TABLE I.—Response to Local Treatment of Wounds

Nature of Lesion	No. of Cases	No. of Cases Infected with		Days before Negative Swab (No. of Cases)														No. of Cases developing Secondary Infection	
				Strep. pyogenes							Staph. aureus								
				Sir. pyog.	St. aur.	1	2	3-4	5-7	8-14	Failures	1	2	3-4	5-7	8-14	Failures	Ps. pyocyanea	Proteus
Superficial and accessible wounds (chiefly operations for plastic repair)	33	10	27	2	1	3	2	1	1	0	3	7	10	5	2	6	2		
Sutured wounds treated through tubes	11	4	11	2	1	—	—	—	1	1	1	2	3	1	3	4	—		
Sinuses	16	5	15	4	—	1	—	—	—	1	—	4	2	2	6	3	1		
Totals	60	19	53	8	2	4	2	1	2	2	4	13	15	8	11	13	3		

streptococci, anaerobic Gram-negative bacilli (*F. fusiformis* and many others unidentified), and various Gram-positive bacilli. The mixed and predominantly anaerobic flora often found in infections derived from the mouth is thus in general sensitive to penicillin, and the results of treatment are as would be expected from this.

**Actinomyces.**—According to the Oxford workers, *Actinomyces* is penicillin-sensitive and actinomycosis susceptible to treatment. We have examined 5 strains, determining their sensitivity by cultivation in a series of broth tubes containing falling concentrations of penicillin, an identical series being inoculated with the Oxford H strain of *Staph. aureus* as a control; the former series was incubated anaerobically for 10 days, during which time it is probable that some of the penicillin activity of the medium was lost. Two strains had approximately the same degree of sensitivity as the standard staphylococcus; they were obtained from cases of actinomycosis of the face, and both appear to have responded well to local treatment. Another, forming a much more compact and firm colony, was 8 times more resistant; the jaw lesion from which it was derived did not respond to local treatment with penicillin. A fourth strain, from a patient with thoracic actinomycosis who died of *Ps. pyocyanea* septicaemia during systemic penicillin treatment, was 4 times as resistant as the staphylococcus. The fifth strain grows normally only in concentrations tolerated by the staphylococcus, but sparsely and typically in concentrations up to 16 times greater; this case (jaw) has not been treated. The sensitivity of *Actinomyces* evidently varies, possibly to a greater extent than observations by this method reveal.

We have had no occasion to examine the sensitivity of strains of other susceptible bacteria, such as the various *Clostridia*, *B. anthracis*, and *C. diphtheriae*.

a series of cases with extensive bone involvement, such as old compound fractures (see Robertson, p. 519), in which we now know this method of treatment to be useless.

The variability of effect seen in Table I probably depends largely on the structure of the lesion, and thus on the feasibility of permeating it with penicillin completely and maintaining this condition. *Strep. pyogenes*, as would be expected from its greater sensitivity, tends to disappear earlier than *Staph. aureus*. Secondary infection with *Ps. pyocyanea* or *Proteus* often developed during treatment in these and other cases, and aroused a suspicion in some minds that penicillin not only fails to inhibit the growth of these organisms but actually stimulates it. Experiments to determine whether this is so are not complete.

#### Estimation of the Penicillin Content of Exudates

Since therapeutic effect depends on maintaining an adequate concentration of penicillin in the lesion, it is useful to know, whether this condition has been secured. If solution is being introduced into an abscess or other cavity, pus can be withdrawn before a further injection is made and its penicillin content determined. This is done by placing it in a cup in an agar plate heavily inoculated with the standard staphylococcus; growth is inhibited in a zone around the cup the width (radius) of which is a measure of penicillin concentration (concentrations of 100, 10, and 1 unit per c.cm. produce zones measuring 20, 12, and 3 mm. in width respectively).

Persistence is most regularly to be expected in closed cavities treated by aspiration and injection. This fact is illustrated by estimations of penicillin content in pus from empyemas so treated: in 14 specimens of pus withdrawn 2 days after the first injection the mean inhibition zone was 9 mm., and after 3 days (7 specimens) 7 mm. In one case pus giving a 6-mm.

zone was withdrawn 5 days after the last injection. Zones of 2 mm. have been observed after 9 and even 11 days, but their significance is doubtful, since pus containing no penicillin has been observed sometimes to produce this degree of inhibition.

Specimens of fluid from other lesions examined in this way total 192. Some of these were from abscesses treated by aspiration and injection with results comparable to those in empyema. The majority were withdrawn either from sinuses or from recent operation wounds sutured over a tube. Table II records the penicillin content in 106 such specimens; only those obtained one day after treatment are included, and others are excluded in which it appeared that penicillin was being destroyed by coliform bacilli.

TABLE II.—Zones of Inhibition produced by Fluids withdrawn One Day after Local Treatment with Penicillin Solution (usually 1,000 Units per c.cm.)

	No. of Cases giving Zones (in mm.) of					
	0	1-3	4-6	7-10	11-15	16-21
Sinuses ..	10	2	3	5	4	1
Wounds ..	18	11	5	5	10	32
Totals ..	28	13	8	10	14	33

Mechanical factors favouring retention again appear paramount in determining results. It is possible that the vascularity, or other properties of the tissue bordering a cavity have also some influence, but clear evidence of this has not been obtained.

#### Estimations of Penicillin Content of Blood

During systemic treatment the penicillin content of the blood should be estimated. This is possible only by determining the bacteriostatic power of the serum either for the patient's own organism or for the standard staphylococcus. All methods for doing this depend on using the undiluted patient's serum and dilutions of it in normal serum as a culture medium; a small inoculum of staphylococci grows in serum in the form of colonies, which may be counted if such cultures are made on slides, the cover-slip being sealed with petroleum jelly. Inhibition of growth in any given dilution may be either complete (no colonies) or partial (fewer colonies than in a normal serum control).

Dosage in this series of cases was uniform, 120,000 units a day being given to adults and a correspondingly smaller dose, approximately related to body weight, in children. The penicillin content of 37 specimens of blood from 13 patients receiving penicillin by intravenous drip or other continuous method of administration is stated in Table III.

TABLE III.—Numbers of Serum Specimens Bacteriostatic to Oxford H Staphylococcus in Different Dilutions

Bacteriostasis:							
Nil in pure serum ..	..	..	..	..	..	..	1
Partial in pure serum ..	..	..	..	..	..	..	5
Complete in pure serum ..	..	..	..	..	..	..	11
Partial in 1 in 2 serum ..	..	..	..	..	..	..	3
Complete in 1 in 2 serum ..	..	..	..	..	..	..	7
" " 1 in 4 serum ..	..	..	..	..	..	..	5
" " 1 in 8 or over ..	..	..	..	..	..	..	5

These variations cannot be fully explained, although one cause of a high titre may certainly be retention due to renal inefficiency; 3 of the 5 specimens listed as "1 in 8 or over" came from the case referred to also by Morgan, Christie, and Roxburgh (p. 515), in which repeated estimations (not listed here), after administration was stopped, showed long delay in excretion. A concentration giving complete inhibition in pure serum is probably adequate for full therapeutic effect, and *in vitro* tests (to be published later) have shown that the rate of death of staphylococci in blood containing penicillin is not accelerated by increasing the penicillin concentration within the range of 0.1 unit to 10 units per c.cm.

When three-hourly intramuscular injections are given, the blood concentration is known to rise rapidly after each injection, then to fall progressively until the next. Specimens obtained immediately before a dose was due gave no inhibition at all in 6 and partial inhibition in pure serum only in 3. A much greater number of such estimations must form the

basis of any judgment on this method of treatment; but to gain an idea of whether dosage is adequate must clearly be more difficult; and on theoretical grounds the maintenance of a steady level by continuous administration seems to me more likely to achieve full therapeutic effect.

#### Comment

This condensed account of laboratory work on cases of which are described by foregoing authors is no more than an interim report on a study still in progress. It is intended to present a picture of the nature and volume of work which is called for from the laboratory if penicillin treatment is to be directed intelligently and, still more, if its efficiency is to be improved. At the same time a few minor original observations are briefly reported which may be of some service to other workers.

The greater part of the technical work here described was carried out by Miss P. M. Waterworth. Her services and the equipment of the laboratory used were made available by the generosity of "Bundles for Britain," which organization provided a fund under the control of Mr. Rainsford Mowlem for laboratory work in connexion with his surgical unit.

## Medical Memoranda

### Reliability of the X-ray Diagnosis of Early Pulmonary Tuberculosis

The case cited by Dr. Sharpe in the *Journal* of Nov. 6, 1943 (p. 579) and the series of letters which followed have brought into prominence the important question as to how far x-ray films of the thorax can be relied upon in the early diagnosis of pulmonary tuberculosis. The following is a case in which a fatal miliary tuberculosis supervened shortly after the lungs were declared to be entirely free of evidence of infection by a reliable radiologist who has had great experience in reading radiographs. This x-ray examination was made while the patient was in hospital suffering from tuberculous meningitis.

An electric welder aged 21 was admitted to hospital complaining of severe headache. Clinical signs of meningitis developed, and laboratory findings confirmed the diagnosis. The radiograph of the chest taken while in hospital was negative. Death occurred on the thirteenth day after admission. Necropsy findings were: a typical Ghon lesion about 1 cm. in diameter lying immediately beneath the pleura in the upper part of the right lower lobe, the lesion involving a vessel of medium size; enlarged caseous glands at the root of the right lung; small caseous tubercles in the cerebral meninges, spleen, kidneys, and adrenals.

The questions which arise are how frequently cases are missed by the radiologist, and what type of lesion it is which fails to show up in the x-ray film. As to the first matter, Dr. Richards, radiologist to the Toronto General Hospital, has collected the statistics of active tuberculosis developing in enlisted men in Canada during the first two years of the war. He finds (*Amer. J. Roentgen.*, 1942, 47, 66) that 16 men who had negative x-ray films on enlistment developed active tuberculosis—a percentage of only 0.004. We are informed verbally by a urologist in charge of one district in Canada, however, that he has seen no fewer than four cases of tuberculous epididymitis in soldiers who must have passed the test of a chest radiograph. This means that a percentage which is not negligible is declared free from evidence of pulmonary tuberculosis after inspection by the radiologist.

#### LESIONS WHICH FAIL TO SHOW UP

As to the matter of the type of lesion which fails to show up in the x-ray film, we are inclined to believe that many localized cases of primary tuberculous infection are invisible in radiographs. For the sake of brevity we may refer to this primary tuberculous pulmonary lesion as the Ghon lesion. It is situated at the periphery of the lung immediately under the pleura, usually not at the apex, and it consists of a small area of caseous consolidation later surrounded by a rampart of fibrous tissue. Spreading from it is a chain of infected lymphatics terminating in a caseous gland in the hilum of the lung. It is a moot point whether this lesion—which is usually small, often less than 1 cm. in diameter—can be demonstrated by x-rays, especially if it be placed laterally and so hidden behind the ribs. When it becomes the seat of calcareous deposit it is more easily seen.

As to the matter of appearances in x-ray films which are suggestive of tuberculosis but which are not tuberculous in origin, probably every radiologist has seen suspicious lesions which disappear after a short time. Virus pneumonia of an

interstitial type and the rare condition of sarcoidosis both give pictures which may be confused with those found in tubercle.

The time which elapses between the exposure of susceptible persons to an open case of tuberculosis and the first radiological evidence of tuberculous disease is frequently three years or more in adults. This is the period of the Ghon lesion. During this interval the earliest evidence that a tuberculous focus is present in the body is the change in the allergic response to tuberculin. Another point of importance illustrated by the above case is that throughout the first few years of infection there is a tendency to bacillæmia, with resultant metastatic foci in various organs such as meninges, bone, kidney, and epididymis. It is remarkable how often necropsies are performed on cases of military tuberculosis without the pathologist being able to assign to one particular lesion the role of primary focus of infection, the fact being that it is a minute primary focus of the type indicated.

We are inclined to agree with Dr. Fawcitt (*Journal*, 1943, 2, 692) that there is no such thing as x-ray diagnosis but there is x-ray evidence, and that this fact is not yet fully appreciated. Nevertheless, mass radiography of recruits, schools, and nursing personnel is wonderfully reliable in spite of the occasional false negative and false positive.

### Tuberculin Jelly Patch Test

**Other Tuberculin Skin Tests.**—Since the introduction of the Vollmer patch test in 1937 much experience of its advantages and disadvantages has been gained. On the whole, it is a satisfactory and comparatively simple method of performing a tuberculin skin test. There is a tendency, however, for the patches to become dry and the tuberculin inactive, with consequent inaccuracies in the results. This has been especially noticeable during the war years. Compared to the Mantoux intracutaneous test, it can be said that the Vollmer patch test with freshly prepared patches is at least 95% accurate.

**Tuberculin Jelly.**—Recently an opportunity has arisen for the carrying out of a series of tests with tuberculin jelly, prepared as follows:

Old tuberculin (tuberculinum pristinum)	..	..	95%
Inert adhesive .. .. .	..	..	5%

**Method of Application.**—The jelly is put up in small tubes, and after an area of skin between the shoulder blades has been carefully cleaned with acetone (for preference) a small portion of the jelly is pressed out on to the cleaned area. (I have found it more satisfactory to use a specific marking, which in my case has been the letter "V.") Without waiting for the jelly to dry, a piece of elastoplast about 1 in. wide and 2 in. long is used to cover the jelly and is allowed to remain on the back for the usual 48 hours. Meantime instructions are given that the child should not be bathed for this period, and after the removal of the plaster the back is viewed daily for several days.

**Reading the Test.**—A positive test is shown by an erythema or slight vesiculation of the skin in the shape of the marking used. A negative result is shown by a completely normal appearance of the skin area on which the jelly was applied.

**Results.**—Experience has shown that with the letter "V," the arms of which are 1/2 in. long, the reaction is equivalent to that of 0.1 c.c.m. 1/100 old tuberculin (intracutaneous Mantoux test). In a recent series of 100 (specially selected) children, to whose backs the tuberculin jelly was applied, both at the Hospital for Sick Children, Great Ormond Street, and the Children's Department, Westminster Hospital, in-patients and out-patients, the following results were obtained:

Result	Vollmer Patch	Mantoux	Tuberculin Jelly
Positive ..	32	35	35
Negative ..	68	65	65
	100	100	100

**Conclusions.**—It would appear that in this series tuberculin jelly was a more accurate method of performing the skin test than the Vollmer patch test. No local reactions of undue severity were recorded. Other advantages appear to be: (1) the much smaller cost of the jelly in comparison with the patches, which is a considerable item in out-patient departments and clinic work; (2) the jelly will keep indefinitely in the tubes and is therefore more suitable for the general practitioner who may use this test only at infrequent intervals.

I have to thank Mr. Drebbin, of Messrs. Allen and Hanburys Ltd., for supplying me with the jelly and for his helpful suggestions.

London.

DONALD PATERSON, M.D., F.R.C.P.

## Reviews

### AN ORNITHOLOGIST ON EVOLUTION

*Systematics and the Origin of Species from the Viewpoint of a Zoologist.* By Ernst Mayr. (Pp. 334, 26s. 6d.). New York: Columbia University Press; London: Oxford University Press

Darwin had a profound knowledge of systematics, palaeontology, and genetics, on all of which the theory of evolution rests. His successors cannot hope to cover so wide a field, though Dr. Huxley has very nearly succeeded in his recent *Evolution*. Dr. Mayr is an ornithologist, whose work has been largely in the present Pacific war zone, and his facts, like those of Wallace, are mainly drawn from the study of living animals and their geographical distribution. The book is absolutely first rate, and every naturalist will find much in it to interest him.

After a very full discussion of geographical variation, the author concludes that some geographical races may develop into species, though he cannot agree with Darwin that "varieties are incipient species," since very few are likely to reach specific rank. The essential step in species formation is the prevention of crossing between two races. Dr. Mayr believes that, in animals at least, this almost always occurs in the first instance through geographical isolation. This may cause such differences of behaviour that the new species will not mate when they get the chance, and simultaneously or later, physiological differences which render the hybrids inviable or sterile. Here he will not convince all readers, though he makes a strong case.

Medical readers will be interested to see that he divides the malaria mosquito *Anopheles maculipennis* without hesitation into six species, which are reproductively isolated from one another, and does not regard them as mere "biological races," even though the adult forms cannot as yet always be distinguished. The student of *Homo sapiens* in his and her infinite diversity will find Mayr's discussion of other "polytypic species," all of whose geographical races can breed together, of great interest. It would have been a wholesome discipline if Hitler on the one hand and some of the more extreme exponents of human equality on the other had been compelled to study the geographical races of some of the birds of New Guinea in order to obtain a biological background for their theories.

While Dr. Mayr's book is not for general consumption, it should be within reach of every student and practitioner of medicine who wishes to keep up with the present position of evolutionary theory on the one hand and zoological classification on the other, as well as every ornithologist. To the student of genetics it presents a vast array of problems, of which the simplest is to determine, for every geographical race described, how far its characters are due to heredity, and how far to environment. I for one am going to re-read it several times.

J. B. S. HALDANE.

### VASCULAR LESIONS AND TUMOURS OF THE SPINAL CORD

*Vascular Abnormalities and Tumours of the Spinal Cord and its Membranes.* By Roger Wyburn-Mason, M.D., B.Chir., M.R.C.P. (Pp. 195, 18s.) London: Henry Kimpton, 1943.

The relative rarity of the pathological lesions with which this volume is concerned must be largely responsible for their comparative neglect. Dr. Wyburn-Mason has been fortunate in having access both to the collection at the National Hospital and to cases coming under the care of neurosurgeons at several other centres. He has given a full, careful, and interesting presentation of his gleanings, which comprise 67 well-illustrated cases. This series represents a substantial addition to the literature, which so far contains little more than twice that number of cases. It will be profitably studied by those who are interested in these lesions, whether from the clinical or from the pathological aspect. The classification follows much the same lines as those previously outlined by Bailey and Cushing, and by Bergstrand. From the last-named, however, he differs in requiring a separate class for arterial anomalies and in including the cavernous angiomas with the telangiectases.

which are held—very credibly—to be precursors of the cavernous lesions. Bergstrand, it may be recalled, doubts the existence of racemose angiomas of purely arterial character. Wyburn-Mason, under the heading of arterial anomalies, describes aneurysms of the spinal arteries in association with coarctation of the aorta, and, further, anomalies associated with, or independent of, cardiac lesions. The latter are, however, unconvincing in the absence of histological verification.

The classification is marred by the inclusion of two dubious conditions—syphilitic aneurysm of the spinal arteries, and lymphangioma. Since these find no place in the author's extensive experience, and, moreover, are based on unsound pathological premisses, they would occupy a better perspective as footnotes than as chapter headings. It is surprising to read, on page 47, that attention is here being drawn to a clinical condition not previously mentioned in the literature—namely, spontaneous subarachnoid haemorrhage. This can hardly be what the author intended to convey, in view of his references to the literature in later paragraphs. His account of the symptomatology of this condition agrees well with that of Gowers.

The style and price of this volume are an agreeable surprise in a wartime production.

### LABORATORY TECHNIQUE IN TYPHUS

*Técnicas de Laboratorio en el Titus Exantemático.* By Prof. G. Clavero del Campo (Director del Instituto Nacional de Sanidad) and Dr. F. Pérez Gallardo (Médico de Sanidad Nacional). (Pp. 185; with 104 figures, 7 coloured.) Madrid: Imprenta de Prensa Española, 1943.

This interesting monograph was published as a sequel to the typhus epidemic which occurred in Spain during 1941-2. In an earlier volume by the same authors, which was also issued by the Spanish Health Directorate, an equally comprehensive review of the aetiology, clinical aspects, and prophylaxis of louse-borne typhus had been given. About half the present volume is occupied by the description of methods of isolating *Rickettsia prowazeki* by guinea-pig inoculation, by anal inoculation of lice, and by culture in the yolk-sac of the developing chick, and a further section deals with the isolation of the rickettsiae of murine typhus. There is a section on the Weil-Felix reaction, on agglutination with suspensions of rickettsiae, and on Giroud's intradermal test. In the remaining chapters the authors describe the preparation of the different types of killed typhus vaccine—namely, those made from rickettsiae grown in the louse-gut (Weigl), yolk-sac (Cox), rat-lung (Castaneda), and rabbit-lung (Durand and Giroud). Every detail of the various procedures described is fully illustrated by photographs and drawings, and readers with little knowledge of Spanish will find it comparatively easy to follow the text, thanks to the numerous and excellent illustrations.

In a foreword written by Prof. J. A. Palanca, Director-General of Public Health, an interesting account is given of the activities of the health department during the recent epidemic. This book should certainly be very helpful to laboratory workers who have had no previous experience of typhus but are likely to make contact with the disease during or after the present war.

### THE ARMY MEDICAL SERVICES

*R.A.M.C.* By Anthony Cotterell. (Pp. 116; illustrated. 6s.) London: Hutchinson and Co.

In *R.A.M.C.* Anthony Cotterell gives a vivid picture of the many-sided activities of the Army Medical Services. In his own words, "the main purpose was to describe a difficult job well done by all ranks in the R.A.M.C., from the generals who advise and plan down to the orderlies washing out the medicine bottles." His description might itself be described as a difficult job well done, for it is a most readable book. A large part is made up of actual experiences in the field, and the author has chosen his material well and is an excellent story-teller. It is natural perhaps that the treatment and evacuation of battle casualties should have the lion's share at the expense of other interesting features, but Mr. Cotterell has managed to cover a very wide field. The problems of malaria control, water supplies, camp hygiene, preventive inoculation, blood transfusion, methods of dealing with psychiatric casualties, the "lead-slinger," and many other special aspects are faithfully dealt with and fitted into their

place in the general plan. One would have liked to see section on the Q.A.I.M.N.S., but it is good to note the author's promise that the sisters are to have a volume of their own.

The doctor or medical officer reading this book may at times be irritated by paragraphs reminiscent of the style of *First Aid to the Injured* or *R.A.M.C. Training*, or, in the section on oral hygiene, of a Health Week leaflet, but it will be borne in mind that these explanations are interesting and helpful to others. The gratitude of N.C.O.s and men of the R.A.M.C. is due to Mr. Cotterell for showing that they have in full measure the hazards and hardships of war with their comrades in the more spectacular branches of the Services, and that they are no less entitled to be called soldiers though nominally protected by the Geneva Convention. If it helps to remove the impression, unhappily prevalent in some quarters and keenly felt by many a humble private, that every nursing orderly is "either a conchie or a crock," this book will do a great deal of good.

### Notes on Books

A Sixth Supplement to the *British Pharmaceutical Codex*, 1934, is published at 2s. 6d. by the Pharmaceutical Press, 17, Bloomsbury Square, W.C.1, by direction of the Council of the Pharmaceutical Society of Great Britain. It contains additions and amendments to the monographs in Part I and Part II, with amendments to formulae in Part III.

The County Accountants' Society (County Hall, Chichester) has published a booklet on *Classification of Patients under the Emergency Hospital Scheme*, prepared by the county accountant of Middlesex. It is believed that Mr. Rothwell's summary, which contains in handy form a complete classification of patients under the scheme, and gives useful information under each classification, will be of value to administrative and financial officers concerned with the scheme. The booklet has been nominally priced at 2s. 6d.

### Preparations and Appliances

#### MODIFIED TROLLEY TO MAINTAIN TILTING DURING TRANSPORT AFTER SPINAL ANAESTHESIA

Mr. T. B. MOUAT, F.R.C.S., surgeon, E.M.S., writes from Wharfedale Emergency Hospital, Sheffield:

After operation with light spinal anaesthesia, or in a shocked patient, transportation back to the ward in a safe head-down position is facilitated by a simple modification of the ordinary type of theatre trolley.

The two tubular supporting pillars at one end have been cut across at their upper ends and two slightly smaller tubes, which are hinged at their attachments to the under-surface of the table, are telescoped into the original table supports, where they are fixed, to maintain the desired tilt, by pins in holes bored through both tubes. The attachments of the pair of supporting pillars under the opposite end of the trolley must, of course, also be hinged to allow the top of the trolley to be tilted in this way.

Our thanks are due to Mr. Sidney Wright of the hospital workshop for his co-operation in carrying out the alteration.

## TREATMENT WITH PENICILLIN

The therapeutic properties of penicillin were first disclosed in animal experiments by Florey and his co-workers<sup>1</sup> in 1940, and their first account<sup>2</sup> of succeeding essays in the clinical field appeared in the following year. These were the days when penicillin was being made only in the laboratory, and supplies sufficed for the treatment of only 5 cases of severe staphylococcal infection and a few of conjunctivitis and other local infections. The next report from Oxford,<sup>3</sup> nearly two years later—an interval during which both production and the quality of the product had been improved—added a further series of cases of staphylococcal septicaemia, osteomyelitis, and cavernous sinus thrombosis, all successfully treated, many cases of chronic sepsis treated locally, and further information about eye infections and the treatment of mastoiditis. These studies laid the foundations of penicillin treatment, and clearly indicated two things: that given systemically the drug will control septicaemia or other extensive and dangerous infections due to *Staph. aureus*, and that applied locally it is the perfect antiseptic when circumstances permit its continuous action. It should not be supposed that staphylococcal infections stand alone in being thus amenable to systemic treatment; they were chosen because the sulphonamides have so little real power over them. Haemolytic streptococci and pneumococci are even more susceptible to penicillin, but the infections which they cause are usually so relatively controllable by sulphonamide treatment that the use of penicillin for them was unjustified. From this point the story is taken up elsewhere than in Oxford, and several further specific uses for penicillin have been described in later papers. These include the treatment of burns, which has been studied by Bodenham<sup>4</sup> and by Clark *et al.*<sup>5</sup>; of septic infections of the hand, where according to Mrs. Florey and Williams<sup>6</sup> a small amount of penicillin will go a long way in preserving function and restoring it rapidly; and the treatment of battle wounds, recently reported on by Florey and Cairns.<sup>7</sup> These are the efforts of our own workers. Clinical study on an even larger scale has been in progress in the U.S.A., and we referred not long ago<sup>8</sup> to a preliminary report on the treatment of no fewer than 500 cases, many of which received systemic treatment; but details of many of the groups of cases included in this total have not yet been published. Much larger supplies of penicillin are available in America, and it is there that the treatment of both gonorrhoea and syphilis has been developed, as we noted in a recent issue.

A year ago, when supplies from commercial sources in England had reached sufficient proportions, some was placed at the disposal of the Medical Research Council, and through its Penicillin Clinical Trials Committee several centres were established for further therapeutic study. A report from one of these centres, taking the form of eight separate papers on different aspects of the subject, occupies the whole of the space devoted to original papers in this issue of the *Journal*. In their introduction Christie and Garrod define the policy of such a centre, and refer to the transition from all-embracing enthusiasm to caution in selecting cases with particular needs clearly in view, which is inevitable when supplies are limited. There is still not nearly enough penicillin available for treating all the cases even of a few conditions, such as staphylococcal septicaemia, in which the value of heavy systemic dosage is fully established. Since the purpose of the work was to break new ground rather than to exploit existing knowledge, such cases had often to be refused. It is nevertheless as well to warn those who will have greater opportunities in the future that even penicillin is no guarantee of cure in staphylococcal septicaemia. Apart from several cases of osteomyelitis in this series with a positive blood culture, all of which did well, there were 4 cases of septicaemia in which 2 patients died in spite of heavy and long-sustained dosage. The opportunity afforded by these and other cases undergoing systemic treatment was taken to study new methods of administration. Florey advocated originally a continuous intravenous drip and later single intramuscular injections at 3-hourly intervals. The disadvantages of the former are difficulty of accurate regulation, liability to thrombosis, and sometimes shortage of veins; of the latter, the ordeal for the patient who must submit to painful injections continued with inexorable regularity by night as well as by day for perhaps more than a week. The merits of both routes seem to be combined in the intramuscular drip described by Morgan, Christie, and Roxburgh, and these authors have also explored the possibilities of infusion via the bone marrow.

A policy at this centre has been to study further the treatment of infections of bone, and two papers deal with this from different aspects. In Robertson's hands the treatment of acute osteomyelitis by the systemic route had the almost uniformly favourable results which have already been reported. Early treatment appears to be essential, the least satisfactory case being one in which it was resorted to a full month after the onset. The account of attempts to treat chronic bone infections, whether haematogenous or due to compound fractures, and whether by local application in various forms or even by the systemic route, makes very different reading. It is indeed a record largely of failure, and surgeons and others who are clamouring for penicillin in order to treat cases of this kind may console themselves with this evidence that their deprivation may not be the misfortune they think. Robertson himself gives good reasons for these disappointing results, and contemplates changes in surgical technique which may improve them. Penicillin is not a magic elixir the mere instillation of which into a sinus or bone cavity will lead to healing. It can deal only with bacteria

<sup>1</sup> *Lancet*, 1940, 2, 226.<sup>2</sup> *Ibid.*, 1941, 2, 177.<sup>3</sup> *Ibid.*, 1943, 1, 357.<sup>4</sup> *Ibid.*, 1943, 2, 725.<sup>5</sup> *Ibid.*, 1943, 1, 605.<sup>6</sup> *Ibid.*, 1944, 1, 73.<sup>7</sup> *British Medical Journal*, 1943, 2, 755.<sup>8</sup> *Ibid.*, 1943, 2, 582.

which it can reach, and it cannot remove dead or irreparably damaged tissue. These findings may usefully be compared with Mowlem's experience in the treatment of osteomyelitis of the mandible. His practice here is to remove all the affected bone, leaving perhaps only a thin lingual plate to maintain continuity. It was formerly necessary to leave the wound open and allow it to granulate. He now closes it completely, having inserted two tubes through which the bone cavity can be filled with penicillin solution from above; infection is thus suppressed and rapid healing is secured. This is a new application of the principle first enunciated by the Floreys, with the new mastoid technique as their example, that septic wounds which are to be treated with penicillin must be sewn up in order to retain the solution. The success of the operation is clearly the effect of radical removal of affected bone, and perhaps nothing short of this will provide the answer to chronic osteomyelitis in other parts of the skeleton. The mandible has two advantages from this point of view: it is easily accessible and non-weight-bearing. Corresponding treatment of some of the long bones may well be surgically impossible.

Several papers deal wholly or in part with various infections of soft tissues. Fraser has begun a study of the treatment with penicillin of staphylococcal breast abscess, and it seems that aspiration of pus and injection of penicillin solution will sometimes replace operation, and usually hasten recovery. It has yet to be decided whether, as is hinted elsewhere in connexion with empyema, it may prove better policy to evacuate the contents of the abscess surgically and rely on penicillin to achieve and maintain subsequent sterility. Barron and Mansfield bring out several useful points in connexion with the use of penicillin in plastic surgery: it has evidently several uses here, as would be expected from the damaging part which pyogenic infection can play, and the usual full accessibility of the infection to treatment. Roxburgh, Christie, and Roxburgh describe the treatment of 75 cases of various diseases of the skin. This is almost a new field and evidently a promising one, at least in so far as the condition treated is due to infection by staphylococci or streptococci. That impetigo should be curable is no new thing, but penicillin seems to achieve this effect more quickly than anything else. That sycosis should be quickly controlled in a majority of cases is decidedly something new, and this achievement, should longer experience confirm it, will rank high among the minor benefits of the discovery of penicillin.

A final paper by Garrod gives an account of the extensive laboratory work entailed by fully controlled penicillin treatment. The necessity for this may well give pause to those who look forward to the wider availability of penicillin, since laboratory service on this scale is not everywhere available; but perhaps greater experience and more standardized methods of treatment may dispense with the need for at least some of this work. New observations reported are the variable sensitivity to penicillin of *Actinomyces*, with corresponding variations in the effects of treating several cases, and the susceptibility to penicillin of mouth bacteria generally, again reflected in the good

results in osteomyelitis of the jaw, a condition of which the flora, aerobic and anaerobic, may be complex. Actual instructions for the performance of laboratory investigations in connexion with penicillin treatment are not given for these the reader is referred to M.R.C. War Memorandum No. 12, the publication of which we noted last week.

We look forward to hearing further accounts of the work on this subject now in progress. The general principles are now understood, but specific new applications continue to be discovered. This is not merely a matter of thinking of something new to treat: it may involve devising a new method of application or a change of surgical technique to suit the altered circumstances created by penicillin. There is thus still room for enterprise, notably in special departments of surgery which so far have had little chance to try their hand with the new weapon.

### CUTANEOUS DIPHTHERIA

Diphtheria in cutaneous and other forms gave a lot of trouble to the Army in the Middle East during the war of 1914-18, and it is once more giving concern to medical officers on service. Major Bensted<sup>1</sup> described what was probably the first epidemic of faucial and cutaneous diphtheria among troops on a military frontier: the epidemic was brought under control by Schick-testing and active immunization. Cameron,<sup>2</sup> Muir,<sup>3</sup> and Marshall<sup>4</sup> describe outbreaks in Northern Palestine and in the Middle East in 1940 and 1941. Cameron tells of the Jewish children in Palestine near the camps with a considerable incidence of nasal, crusted, discharging sores, and refers to a local description by Bernfeld.<sup>5</sup> Lack of full laboratory facilities prevented the complete examination of strains of diphtheria-like bacilli found in the children or in military patients, but of the 40 cultures obtained from clinically accepted cases of diphtheria, 31 strains proved virulent on test. Some were reported avirulent, but the author points out that the suspension for animal tests was made in saline—a fluid noxious to diphtheria bacilli.<sup>6</sup> Cameron discusses whether contact with horses might account for infection, but he failed to find bacilli in the throat, nose, or skin of horses or in the fodder. Parish and Okell<sup>7</sup> found virulent *C. diphtheriae* in three of 13 swabs taken by Dalling from wounds in horses occurring in a military camp in Scotland. Cameron and Muir<sup>3</sup> treated their epidemic of cutaneous diphtheria by isolation, Schick-testing, and active immunization. Their observations agree in all important points with those of Bensted and the American Official History of the War.<sup>8</sup> Cutaneous diphtheria may complicate any form of wound, burn, blister, impetigo, eczema, Oriental sore, whenever faucial diphtheria prevails and the patient may infect his own skin. As skin lesions have been followed by severe paralysis, it is wise to give such patients

<sup>1</sup> *J. R.A.M.C.*, 1936, 67, 295.

<sup>2</sup> *Edinb. med. J.*, 1943, 50, 1.

<sup>3</sup> *Lancet*, 1942, 2, 720.

<sup>4</sup> *Med. J. Austral.*, 1942, 2, 14.

<sup>5</sup> *B. J.*, 1942, 2, 154.

<sup>6</sup> *B. J.*, 1942, 2, 73.

<sup>8</sup> *U.S. History of the World War*, 1928, 9, 259, Washington.

an immediate and substantial dose of antitoxin—e.g., 15,000 units. Swabbing of contacts, Schick-testing, and active immunization have, even under war conditions, given a rapid and satisfactory control of epidemics.

When the local lesion comes under medical care the crusts may be removed by saline packs or baths or with glycerin magnesium sulphate or hydrogen peroxide, revealing an ulcer with greyish, membranous slough. Dressings cut to fit accurately in the wound are valuable; hairs around the edge are removed and the skin protected from further infection. The rapidly forming granulations are carefully protected; scarlet red ointment and the aniline dyes have been much used. (Harries<sup>9</sup> gives a valuable review of cutaneous diphtheria.) Carrier rates of from 4 to 3% were observed by Cameron. The few persistent carriers were cured by tonsillectomy. H. Williams<sup>10</sup> recently described an unusual series of cases. Over a period of eight months 19 patients in a military hospital yielded positive cultures a few days or weeks after admission and were found to be suffering from diphtheria of the skin or eye. Six had conjunctival infections, and one patient suffered grave damage to both eyes. The 19 patients were transferred to the isolation hospital; all received antitoxin, and fortunately no paralysis developed. During the same period 17 cases of faucial diphtheria and one of diphtheritic rhinitis, including seven of the staff, came from the same military hospital. Williams suggests the need for more frequent bacteriological investigations of skin infections. Cameron and Marshall both stress the need for active immunization of troops in the Middle East. This plea comes also from Wheeler and Morton,<sup>11</sup> who describe a severe epidemic at Halifax in Canada. The diphtheria occurred there at much later ages than usual; in females the greatest incidence was in the 20-25 age group. The Halifax epidemic was presumably maintained "by the exchange of infection, between the soldiers, sailors, and visitors and their wives or sweethearts in the town."

It is not easy to see clearly the relationship between McLeod's types of diphtheria bacilli and the distribution of the disease. The Halifax outbreak was thought to be the first on the West side of the Atlantic due almost entirely to the gravis type. Murray<sup>12</sup> records a curious position on Witwatersrand in South Africa. Intermedius strains were never recovered from local cases of diphtheria; about 85% of local infections were due to mitis, and the case mortality was high—about 9%. Murray believes that with a high Schick-positive rate in the community and a low carrier rate among children the stage is set for an explosive outbreak at any time from the importation of a more virulent strain; he concludes that active immunization is urgently necessary. Since in certain districts the predominant type may alter from year to year and even from season to season, we obviously have still much to learn. The artificial immunization of some three millions or more of children in England during the past few years may result in disturbance of type distribution or even in the prevalence of types difficult to classify.

## CARE OF THE PREMATURE INFANT

One important way in which neonatal mortality can be reduced is undoubtedly by better facilities for the care of the premature infant. It is estimated that about half the deaths in the first month of life occur in the prematurely born, and experience has shown that organized effort can do much to improve the chances of the immature infant. The often-quoted Chicago figures bear this out, for coincident with a reduction in the neonatal death rate in that city from 37 per thousand live births in 1925 to 18 in 1940 there was developed a city-wide plan for dealing with the premature infant. In this country a start can be fixed in the year 1937, when a joint committee of the Royal College of Physicians of London and the Royal College of Obstetricians and Gynaecologists put forward a recommendation that the "5½ lb. or less" standard should be accepted as a working definition of a premature or immature baby "for the purposes of comparison of records." The next landmark is in the issue of a circular by the Ministry of Health to all welfare authorities, dated March 22, 1944, on the care of premature infants. This is based upon the recommendations of the Minister's Advisory Committee on the Welfare of Mothers and Young Children, and while it is quite clear that many of the suggestions cannot be put into effect at the present time because they involve staff and accommodation they give local authorities a clear lead in their planning for the future. First comes the "provision of accurate information"—namely, a means of securing notification by the simple device of having the weight of all newborn infants noted on the notification of births card when this is 5½ lb. or less. For the baby to be looked after in its own home importance is attached to certain details of accommodation, equipment, and expert services. A list of special equipment, to be lent by the authority when necessary, includes draught-proof cots, suitable clothing, hot-water bottles, electric blanket pads, special feeding-bottles, thermometer, and mucus catheters. A supply of expressed breast milk is also recommended when this is necessary. Specially trained midwives or health visitors are mentioned, and the services of a paediatrician are to be available. Home helps also come into the scheme. For immature babies born in hospital or admitted because of the need for institutional care the circular enters into important details as regards accommodation. Warm rooms with "cooling-off" facilities and regulated humidity receive recognition, and details of nursing staff are set out with the object of securing skilled care and continuity among the senior staff. A paediatrician is to be attached to all maternity units and his services made available for all special units for premature babies, a reform for which both obstetricians and paediatricians have been pressing. A special form of transport is mentioned, and the circular concludes with an important reference to the follow-up of infants "immediately" on discharge from hospital to their own homes. Action on the lines of the circular is long overdue, and it is to be hoped that authorities will lose no time in putting into effect as much as is practicable now.

## WARRINGTON YORKE MEMORIAL FUND

The late Prof. Warrington Yorke was a product of the Liverpool School of Tropical Medicine, and one of its most distinguished members. In addition to his jealous maintenance of the high standards set by earlier workers at the school he earned for himself an international reputation in the world of medical science, and his outstanding original work on trypanosomiasis, blackwater fever, the nematode parasites, and many other parasitic and tropical diseases has permanently enriched our knowledge of these

<sup>9</sup> Hurst, *Medical Diseases of the War*, 1943, chap. 25, London.

<sup>10</sup> *British Medical Journal*, 1943, 2, 416.

<sup>11</sup> *Amer. J. Publ. Hlth.*, 1942, 32, 947.

<sup>12</sup> *S. Afr. med. J.*, 1942, 16, 247.

subjects. In the latter part of his career, so untimely cut short, Yorke turned his exceptional energy and ability more and more to the elucidation of the mode of action and the therapeutic value of chemical compounds, especially in parasitic diseases. As a direct outcome of his pioneer work new potent weapons were forged against a number of diseases, in particular leishmaniasis and trypanosomiasis. These discoveries were of far more than academic interest; indeed, it may be said that Yorke's introduction of drugs of the diamidine series is making it possible to master kala-azar in those parts of the world where the disease is peculiarly resistant to the antimonial compounds. Just before he died he had initiated further studies in chemotherapy, and it was his aim to promote chemotherapeutic research in Great Britain to the front rank and firmly to establish Liverpool as one of its leading centres. To that end he laid a solid foundation on which to build.

The Council of the Liverpool School of Tropical Medicine feels that a fitting memorial to this remarkable man would be to place on a firm financial basis the recently created Chemotherapeutic Research Department, where the work he inaugurated will be continued in association with his name. To this end a Warrington Yorke Memorial Fund has been opened, and the Council believes that Yorke's many colleagues, friends, past students, and others who have benefited by the great advances which he helped to make in tropical medicine and hygiene during his forty years of service, will wish to be associated with this memorial. The Council of the School would welcome subscriptions, however small, which should be addressed to: The Honorary Treasurer, Liverpool School of Tropical Medicine, Chamber of Commerce, 1, Old Hall Street, Liverpool.

### SURGICAL SERVICE FOR INDUSTRY

The Birmingham Accident Hospital has completed its third year. It was a pioneer effort, at least on such a scale, and it has attracted observers from various parts of the country whose institutions have wished to profit from the Birmingham experience. Last year the number of new in-patients was over 2,000, and the number of day-ward cases 2,500. These latter are patients admitted to a ward for less than twenty-four hours, but requiring an anaesthetic, an operation, and a recovery period in bed. We can well believe that the short-stay ward is the busiest and the most expensive in such a hospital. In addition there were some 18,700 new out-patients, and nearly 3,000 new patients treated in the rehabilitation department. Altogether the total daily attendances number something like 400—an indication of the frequency of accidents, mostly minor no doubt, in modern high-pressure industry. The work of the out-patient departments is divided into three groups: fractures and the more serious types of injury; injuries without bone damage but including infections; and, finally, rehabilitation. For each of these groups there is an appointments system, so that waiting-time, especially to be avoided in an industrial hospital in war, has been greatly cut down. The complaint, however, is of shortage of medical staff. The medical staff numbers only ten, with three consultants. It is hoped that when the new out-patient department now being constructed is ready and equipped with new facilities it will be appreciated that the allotment of more medical staff to an institution of this kind would mean, among other things, economy of medical man-power.

One-sixth of the total floor space at Bath Row is devoted to special departments concerned with rehabilitation, meaning physiotherapy, physical training, and occupational therapy; and in all these the surgeons who have been

engaged from the first in the treatment of the particular case are present to supervise these later phases of recovery. Not everyone appreciates how individual a thing is restoration to fitness. This work does not lend itself to the construction of precise schedules. One man's corrective is another man's setback. The work calls for great adaptability on the part of the surgeon, of those who carry out his instructions, and of the patient himself. In industrial accidents rehabilitation and treatment are intertwined. They begin together on the day of the injury, and treatment ends with rehabilitation when the man is restored so far as possible to industrial and social capacity. Moreover, rehabilitation includes more than getting an injured limb back to full function. There may have been a more serious disturbance in the patient's social background, and, however effective the games instructor and the occupational therapist may be, they cannot achieve full restoration so long as the man is fretting over his domestic and economic problems. Therefore the social service department is as important as any in a rehabilitation centre.

Another participant in the work is the industrialist. An experiment has been undertaken by the Birmingham Accident Hospital in conjunction with the Austin Motor Company in which the firm has fitted up a workshop at its factory, under the supervision of the works medical officer, for the employment of disabled workmen. When the treatment of the men in hospital has reached a certain stage of recovery the rehabilitation methods can be stepped up to production level, using the same machines as in the factory, perhaps with some adaptations, and the man begins to feel that instead of playing at industry he is again a unit in the industrial organization. Up to the end of last year about 150 disabled persons returned to normal employment after passing through this special workshop. The scheme of a rehabilitation workshop attached directly to industry and at the same time closely co-operating with the hospital has been a success, and it is hoped that with the co-operation of other Birmingham industrialists it may be extended. The subscriptions to the hospital from industry during the year amounted to just upon £18,000; the City of Birmingham gave £10,000; and contributions on account of services amounted to £11,500 from the Hospitals Contributory Association and some £12,800 from the Ministry of Health; but there is an excess of ordinary expenditure over ordinary income of £4,000.

An industrial hospital offers fresh fields for research. The Medical Research Council has acknowledged this by establishing two research units in Birmingham. One of these is concerned with burns and is under the care of Col. Leonard Colebrook (whose letter in the *Journal* of March 4, page 342, on the first-aid treatment of thermal burns and scalds will be fresh in the minds of readers). The other unit, under Prof. A. A. Miles, is concerned with the bacteriological side of wound infection in industry. This unit has studied during the year over 5,000 swabs from more than 1,000 wounds, and on the basis of the survey, and with the co-operation of the hospital clinical and nursing staff, a new technique of wound dressings has been instituted. An eight-months research on the use of penicillin in the healing of wounds and various septic conditions has been completed during the year by Dr. Ethel Florey, and it is mentioned that about 1,000 man-days were saved by the treatment of 35 industrial cases with this preparation. But penicillin is not yet available in sufficient supply to be used in the hospital. The arrangement of these researches is another example of the enterprise shown in this field, and there is every advantage to be gained from a study of such problems on the spot—that is to say, in a hospital which keeps an open door for the daily victims of the industrial machine.

## Correspondence

### Reform in Medical Education

SIR.—Dr. Douglas Guthrie (March 25, p. 432) is right that the principle which is fated to co-ordinate our ever-multiplying medical specialisms need not be sought in modern psychology. Speaking generally, this latest "subject" (which emanated originally from the decadent great-city life of Greater Germany) is itself but another specialism, isolating a "psyche" from the rest of life. How then, asks Dr. Guthrie, are we ever to supply medical students with the first principles of the healing art? He thinks, by teaching them the history of medicine. I should greatly doubt, however, whether this will prove a solution, and, apropos, may I touch on some personal experience? Before the last war, being in general practice in Edinburgh, I devoted a lot of my spare time to a survey of the whole field of medical history, and even gave lectures on the subject. Incidentally I translated for the Loeb Classical Library one of Galen's most characteristic shorter treatises, and became very familiar not only with the vocabulary but with the outlook of this greatest synthetic medical mind of antiquity. I cannot speak too highly of the stimulating effect which this study and discipline, being grafted on my own daily experience of practice, had on my own mind, and how it deepened my appreciation of and love for the *ars medendi*. But I firmly believe that the average medical student of to-day would, by reason of his preliminary training, be incapable of profiting by lectures on this topic. To the large majority of these young men it would just prove another "extra subject" to be memorized along with all the other "facts" of an already grossly overloaded curriculum, thus fragmenting their minds more than ever. Only experience of general practice, and preferably of country practice, where the doctor is still known much more on his own responsibility than in the cities, can breed a mind capable of absorbing and profiting by the cultural side of medical humanism.

If the powers that be, including the framers of the present White Paper, were really, in the main, concerned with the health of our people and not, in the main, as they are, with making the world safe for bureaucracy, I would even now ask a favour of them. I would ask them to confine their legislative zeal to two enactments—one privative and the other constructive. From the National Health Insurance system I would ask them to cut out, by force if necessary, at least another 50% of this certificate-signing business which is now driving so many members of our profession desperate, if not melancholy mad. And the positive measure would be to make every young graduate begin his professional career by serving as an apprentice for two or three years to an established country doctor. This would be by far the most practical way of ensuring that "return to Hippocrates," with its synthetic and practical aim, which Dr. Douglas Guthrie and others so properly desiderate. It would rear a race of doctors of whom many, I believe, would eventually become capable of profiting by a study of the history of medicine. Such, however, should not be lectured to overmuch. They would need only to have their attention directed to the valuable material available, when, I am convinced, they would grasp it with open arms. Also they would grasp it each in his own way—which, after all, is the best kind of individualism.—I am, etc.,

North Queensferry, Fife.

A. J. BROCK.

### Shock Treatment of Mental Disorder

SIR.—Dr. Kalinowsky's very wise letter on this subject (April 1, p. 453), and the previous correspondence, once again raise the primary issue—are there in fact any diseases of mind *qua* mind? Is mind, whatever and wherever it is, capable of disease? Or are the abnormalities of speech and behaviour, at present so often regarded as being evidences of purely mental disease, in fact due to structural or biochemical defects in the nervous system, including the brain? In other words, are they really dependent upon the condition of the cells, tissues, or secretions by which mind—under any hypothesis

as to its nature and locality—can only, in this everyday turns feed and express itself?

The true In the absence, for instance, of post-mortem obsec visual and a knowledge of the action of the responsible spirid.14 io. the speech and behaviour of a man suffering from cHence, syphilis might well seem—and did probably once seen the be a purely mental disease, approachable only by psycholover, methods. But research has come to show that the anti-s of behaviour, the grandiose ideas, the decaying standardat a personal cleanliness, are in fact due to structural change a to some extent curable or at least preventable by appropri. It treatment of the invaded or threatened tissues. Other examplth can be readily thought of.

It May it not therefore be possible that the less gross aberrations of speech and behaviour associated with such conditions as schizophrenia, melancholia, hysteria, and the great group of anxiety and other neuroses are similarly due to structural or biochemical defects in nerve and brain tissue, relatively small perhaps and at any rate not yet discovered? We do not know the exact means whereby shock therapy can apparently transform and bring back to normal—at least for a time—aberrations of speech and behaviour. But it is difficult to believe that its action can be other than organic—an effect upon tissue and material processes.

To accept this view is not to decry the value of psychiatry, although it may challenge the foundations upon which some people base it. Thus A may have been bullied in youth, had dominating parents, and been shut up in a dark cupboard as a punishment. But he does not develop either an inferiority complex or claustrophobia. B, who has had the same experiences, does. The difference between them may still be explained by some relative defect in B of nerve or brain tissue or biochemical adjustment. But, pending the discovery of this, the psychiatrist can do a very great deal in providing B with a sane outlook on his handicap and a crutch to mitigate it. Just, however, as the anxiety and irritability so often associated with hyperthyroidism disappear after a successful thyroidectomy, so in future—if the possibility is acknowledged and sought for—may the anxiety neuroses and many other hitherto supposedly purely mental affections become removable by an appropriate treatment of material cells, tissues, or secretions.—I am, etc.,

London, E.C.1.

H. H. BASHFORD.

\*. But the problem remains—how does the psychiatrist provide "material cells, tissues, or secretions" with "a sane outlook"?—Ed., B.M.J.

SIR.—In his recent letter from New York (April 1, p. 469) Dr. Kalinowsky, while agreeing that convulsion therapy promotes accessibility to later psychotherapy, still maintains that the latter is of secondary importance. From the purely utilitarian standpoint he is correct, though he himself expresses disappointment at the empiricism with which the treatment remains enshrouded. I write now to offer certain suggestions and to draw attention to certain facts which seem to throw light upon the *modus operandi* of electrical convulsion treatment (E.C.T.).

There are two facts which will be generally admitted by all exponents of the method: first, that some degree of amnesia is to be expected, at least for a time; secondly, that there is a tendency for the patient to relapse, a tendency seemingly inherent though not invariable. In the writer's opinion these two different tendencies are in a measure inversely related. Dr. Kalinowsky correctly stresses the more striking success of E.C.T. in the psychotics rather than the psychoneurotics, pointing out that it is precisely where psychotherapy is most applicable that E.C.T. relatively fails. Now, it is the degree of insight, or, in other words, of conscious inner perception, of the trouble which distinguishes the psychoneurotic from the psychotic patient. In short, the greater the degree of higher conscious perception the less is the response to E.C.T. Here we have an array of facts—which incidentally could be added to—which seemingly all point in one direction—namely, towards the view that the production of amnesia is closely related to the improvement which ensues. The degree of amnesia produced doubtless varies according to the degree of consciousness which pre-existed in the psychical system

hort, Yor world,

...ed psychical systems where  
to a temporary total abolition.  
ect, it means that, while we are  
elief, we do so only by diminishing

It is because the amnesia is transitory  
to relapse and their repressed conflicts  
this carries the inevitable corollary that  
nt in accessibility afore-mentioned is more  
since the deeper systems will have become  
ssible. This artificially produced accentuation  
diametrically opposed to the aim of psycho-  
i, of course, is concerned with the removal of  
the widening of consciousness.

Further investigation these findings and views are  
they will clearly preclude the hope that E.C.T. is  
d ever likely to further scientific understanding of  
d and its processes. Nevertheless, I still hold the view  
n E.C.T. we possess the most generally applicable, and  
efore upon the whole the most valuable, method of treat-  
nt in vogue in psychiatry to-day.—I am, etc.,

Warlingham.

WM. H. SHEPLEY.

### Vaccination against Smallpox

SIR.—In the annotation on vaccination against smallpox (*Journal*, March 18, p. 399) it is stated that "ordinarily a single linear scratch one-quarter inch long is sufficient." In the recent epidemic in Edinburgh the officially issued instructions were: "The actual vaccination should consist of three parallel strokes  $\frac{3}{4}$  in. long and  $\frac{1}{4}$  in. apart." This reveals a very pronounced difference of opinion among authorities. I find that in Price's *Practice of Medicine* (4th ed., 1934) it is stated that "the degree of protection afforded against smallpox is in some degree proportional to the extent of the vaccinal lesion, and the resulting scars should, together, cover an area of not less than half a square inch. Hence the advice always to make at least two insertions and preferably four." In the 1942 epidemic in Glasgow the scarification officially prescribed was "three strokes  $\frac{3}{8}$  in. long and  $\frac{1}{8}$  in. apart."

In the above-mentioned annotation the writer, after saying "ordinarily a single linear scratch one-quarter inch long is sufficient," goes on to say that "in the presence of an outbreak of variola major three well-spaced incisions may be made to give a more solid immunity." It is difficult to follow his reasoning. Surely in any case—whether in the presence of an outbreak of variola major or not—the highest possible immunity should be one's aim.

After the lapse of more than 100 years since Jenner's discovery it seems strange that there should be no general agreement as to the best way of making the inoculation.—I am, etc.,

Tunbridge Wells.

E. WEATHERHEAD.

\*\* The general decline in the acceptance of vaccination, the mild character of smallpox then prevalent in this country, and the occasional occurrence of post-vaccinal encephalitis led the Committee on Vaccination to issue an Order in 1929 directing public vaccinators to make a single linear insertion, which was calculated to protect against the less virulent virus and unlikely to be followed by untoward sequelae. In the absence of an outbreak of variola major, however, 2, 3, or 4 insertions are advisable in order to give a greater degree of immunity, for collected data about smallpox in vaccinated persons indicate that the degree of protection is proportionate to the area of scarring.—Ed., *B.M.J.*

### Vitamin D in Rheumatism

SIR.—Your annotation on the subject of vitamin D in rheumatism calls to mind a problem in the mechanism of that disease which caused me some difficulty at the time. I had formed a satisfactory hypothesis to account for the similarity between the agents which brought about temporary cure in leprosy—I was looking after some lepers at the time—and those used in rheumatism. This hypothesis was severely shaken by an account which reached me of the work of Dreyer and Reed with vitamin D in rheumatism (1935).

For those who are unfamiliar with the treatment of leprosy it is necessary to state that many agents which are known

to cause a recession of skin lesions in leprosy are similar or identical with those reported to cure rheumatism. As example, intravenous T.A.B. vaccine has its advocates in leprosy. Sometimes a more severe shock—intravenous milk, or dyestuffs of some kind, or a large quantity of salicylate—is used in leprosy. Gold and sulphur injections are popular in the treatment of both diseases. Intercurrent infectious diseases have similar beneficial effects in both leprosy and kala-azar, for example, in leprosy being typhoid and measles or acute hepatitis in rheumatism. In seeking the mechanism of such cures the study of rheumatism, where clinical observation has been more extensive and more accurate, offered great promise.

The one factor which I found common to all the cures that cure rheumatism is that which I have labelled *debility* (1942). Whether it is induced by the accidental trauma of falling down and fracturing a femur or by the more deliberate and calculated procedure of "bone forage" does not matter much, provided it is really severe. Whether a patient gets jaundiced or pregnant the beneficial effects on her rheumatism are the same. So far as his rheumatism is concerned it is a matter of indifference whether the patient suffers from gold poisoning with, say, 5% mortality, or atophan poisoning with 45% mortality; in both cases, whether he lives or dies his rheumatic lesions fade. On the surgical side Leriche started with quite a plausible theory to justify parathyroidectomy or sympathetic ganglionectomy. But the theory was exploded by Simon and Weill, who got the same magical results from a mock parathyroidectomy.

It was becoming evident to me that in leprosy and in rheumatism if you knocked the patient about sufficiently you broke down his resistance—of which the lesion in either case is the anatomical expression—with at least temporary good results. On the medical side the more poisonous the drug the better the result, and by raising the dose it is possible to make the pharmacological properties of all drugs converge to a point where they repress the lesions of rheumatism or leprosy. The surgeon who finds, or imagines he finds, sufficient reason for a major operation to cut out the parathyroid, or pretend to cut it out, to excise the gall-bladder or uterus or other septic focus, to chisel away a piece of tibia, or to remove the lumbar sympathetic ganglia, appears to achieve really good results. But the operation must be a major one. Brutality, it seems, yields better dividends than sympathy and sanatorium regimen in the treatment of rheumatism.

At this stage of my observations I was confronted with an account of the work of Dreyer and Reed with vitamin D in rheumatism. Here, it appeared, was the vitamin which controlled calcium metabolism being used to restore the diseased bone to a state of healthy resistance. This was rather disconcerting from my point of view. The report which I had read like your own account, made no mention of dosage. Park (1938), reviewing the toxicity of vitamin D with special reference to its use in rheumatism, considers that 200,000 units daily is the maximum safe dosage. To achieve results in rheumatism, as I might have guessed, the dosage has to be pushed, in some cases, to 1,000,000 units a day.—I am, etc.,

Albury, Guildford.

WILLIAM HUGHES.

### The "Extra Pharmacopoeia"

SIR.—I am sorry that Mr. Linstead finds it necessary to protest on behalf of the Pharmaceutical Society against my review of the latest edition of Vol. II of the *Extra Pharmacopoeia*. The most serious part of his letter is the suggestion that my duty was not done conscientiously, and that I deliberately looked for material to give spice to my criticism. Now, I have been using the *Extra Pharmacopoeia* as a book of reference quite regularly for the last seven years, and recommending it warmly to others. I may not know much about it, but that is not because I am unfamiliar with the book. If I boil down the main complaint of my review and put it forward in the most serious manner, I would say that the two volumes are largely spoilt by the inclusion of information of no interest or importance. This amounts to something like 60% of the

tal information in the books. The presence of this matter greatly reduces the accessibility of the remaining 40%, which consists of first-rate material most carefully collected. Here again I would draw a distinction between analytical methods and information about new medicines. The former is very well done, while the latter is much less well done. I expect the main trouble lies with the size and shape of the book. The printing is far too small. Further, although a great deal of work has been done in preparing the book, not enough thought has been given to the general arrangement. The layout of these two volumes needs to be completely recast.—am, etc.,

YOUR REVIEWER.

### Characteristics of Vision in Fine Work

SIR,—The interesting study (March 18, p. 387) by Ida Mann and Dorothy Archibald of a selected group of women employed on extremely fine work draws attention to certain characteristics of vision which are of special importance for the comfort and success of close workers. These characteristics, and in particular the stereoscopic sense and muscle balance at the near point, are not revealed by the reading of Snellen's types, which is sometimes the only test made in the factory when, indeed, any visual selection test at all is applied. The group studied by the authors came into being, as do many similar groups, "by a process of natural selection," and there is reason for believing that much time is now wasted in giving preliminary training to persons who ultimately prove unsuitable for fine work.

Similar groups of persons employed on fine work were studied by Weston and Adams in a series of investigations made for the Industrial Health Research Board during the period 1927-9, the results being published in three reports.<sup>1-3</sup> Their primary aim, however, was to test the value of applying a theoretically probable measure by which the exacting demands made by the work upon the capacity for accommodation and convergence—even when the work is well lighted—would, in effect, be reduced to comfortable limits. This consisted in giving the workers, including those found to be emmetropic and free from phorias, special spectacles with suitable convex lenses and prisms base in.

The groups studied were employed on various fine processes, including linking (hosiery), mounting lamp filaments, and inspecting steel balls for minute flaws. Though most of the workers had long experience and said they were able to do the work without eye-strain, almost without exception, after using the spectacles for some weeks, they reported feeling more comfortable at work and less tiredness of the eyes after the day's work. In nearly every case there was also an increase, often substantial, in their output when the glasses were worn. As might be expected, this increase was generally proportionately greater for persons having errors of refraction or muscle balance, which were also corrected by the glasses supplied, than for persons needing no such correction. Nevertheless, in one process the average increase found was as much as 26% for "normal" persons. The findings in these studies show that the process of natural selection only eliminates the grossly unsuitable individuals. Others, whose characteristics are not so good as they should be—and might be with suitable assistance—carry on with fine work for years, and become so habituated to the strain it occasions that they cease to realize and admit it as such until working without it is experienced.

In their study Mann and Archibald obtained actual dimensions of the task object and the viewing distance in order to establish, on a basis of analysis and measurement, the standard of acuity required for the work. It is encouraging to note this application of scientific method to the problem involved. As yet, a similar procedure has been followed too rarely in dealing with the problems of vision in industry. It was, however, the basis of proposals put forward by Beutell (1934)<sup>4</sup> for determining necessary values of illumination (and, as Lythgoe showed (1932),<sup>5</sup> visual acuity is a logarithmic function of illumination), and subsequently by Weston<sup>6, 7</sup> in connexion with standards of both lighting and vision for industry.

Unfortunately, an easily made slip in calculating the size of the retinal image considered by the authors leads them to give a value which is ten times the true size. The error lies

in the conversion of the dimension of the gap between turns of the spiral filament from inches to millimetres. The true size of the image of this gap is 0.00025 mm., and the visual angle is 3.125 in. The authors mention the angle 24.14 in. as being usually given for the limit of resolvability. Hence, instead of the retinal image of the gap being larger than the resolvable limit, it is actually well below it. However, "Sberrington has found that osmic-stained nerve fibres of 4  $\mu$  diameter are visible to the naked eye,"<sup>8</sup> and, viewed at a distance of 250 mm., an object of this size would give a retinal image of 0.00027 mm. and a visual angle of 3.39 in. It may thus be just possible to see the gap between turns with the naked eye, but certainly the unpractised eye sees a filament of the kind described simply as a single thread and not as a spiral. Using the loupe the authors mention (magnifying about 8 diameters), the image of the gap would be enlarged sufficiently to subtend the limiting angle quoted by them—i.e., about 24 in.

This error, in so far as it affects the authors' conclusion regarding the acuity required for the work, means that a standard better than 6/6—in fact, the best possible—is desirable. There is, however, some doubt whether the detail taken as the criterion of the fineness of the work is really that which the worker normally attempts to discriminate with the unaided eye. Two turns of wire in contact would produce a dark spot in the coiled thread, and, since the diameter of the wire is given as 0.00057 in., such a spot, when viewed at a distance of 250 mm., subtends an angle at the eye of about 25 in. It is probably this, and not the regular gap between two turns of the spiral, which is the "critical" detail. Even so, it remains true that the highest acuity is needed if the work is to be done satisfactorily, and mostly with the unaided eye.

However, it may be inferred from the investigations cited above that even emmetropes with good muscle balance in near vision would derive benefit from the use of convex glasses with suitable prisms for this exacting visual task.—I am, etc.,

### Intelligence and Season of Conception

SIR,—Mr. Penman (April 1, p. 471) points out that Fitt and others have shown that there is an association not only between season of conception and intelligence but also between season of conception and such things as stature, weight, hand-grip, and infant mortality. But he is in error in supposing that this is an objection to the argument of my paper (March 4, p. 320). It is, on the contrary, just what would be expected, because it is well known that these things are positively correlated. What is true of one is likely to apply to all. Mr. Penman might like, however, to have a few figures illustrating these associations from the group of children who provided the data. The correlation between intelligence and stature in a sample of about 800 was of the order of +0.2. In regard to the association between intelligence and early death figures are available for three samples: (1) the brightest 4%; (2) the median 4%; (3) the dullest 8%. The results are as follows:

	Group 1	Group 2	Group 3
Average number of living full sibs ..	1.95	3.54	5.63
Average number of dead sibs ..	0.13	0.32	0.53
Average number of stillbirths ..	0.03	0.10	0.17

\* When all mothers have passed the age of 50

In view of the method of ascertainment the true family size is given approximately by the number of sibs, omitting

in each instance the child who brought the family into the experimental group. Thus the mothers of the dumbest children have 2.6 times as many living children as the mothers of the brightest. But they had 4.0 times as many who died before the observations were made and 5.6 times as many stillborn children.

The superiority of winter children demonstrated in the mass studies is to be ascribed to the slight tendency for more intelligent parents to have proportionately more children conceived at that time. Moreover, it is likely to be found that this applies to physique as well as intelligence. It is, of course, possible that this larger effect might mask a smaller one due to a direct seasonal influence on the mother or the developing child. Should this prove true the effect could be in either direction, and, to hazard a guess, it would not be surprising to find (if season of conception does have any direct influence) that for the child of any particular pair it is spring-summer conception which is the more favourable. In this matter it is the less intelligent (and those of poorer physique) who approach more closely to what must be presumed to be the remnants of the natural rhythm. It is difficult, however, to imagine any convincing proof of a direct effect due to season of conception which does not depend on showing that children conceived during a particular season are superior to their brothers and sisters conceived at another.—I am, etc.,

London.

J. A. FRASER ROBERTS.

### Chronic Pulmonary Catarrh in Childhood

SIR,—In the words of Chevalier Jackson "all is not asthma that wheezes." Taylor (April 1, p. 453) has described a condition in children simulating asthma which he calls "chronic pulmonary catarrh." It is probably the commonest pulmonary condition met with in children who almost invariably give a history of previous lung infection such as pneumonia, measles, or whooping-cough. The condition in the lung is probably comparable to chronic tonsillar infection with cervical adenitis, with which it is often associated, and methods of treatment outlined by Taylor must be tried in an attempt to prevent the attacks occurring while the chest cage is soft and easily deformed. These can best be given at an open-air boarding-school, but unfortunately, owing to lack of accommodation in these schools at the moment, length of stay is usually confined to six months or less. This is quite useless for these "chesty" children, who immediately revert to their attacks on returning home. Although the trouble may not start as a psychological problem, it soon becomes one if the child remains at home in the surroundings of over-anxious parents. I would like to see a sufficient number of open-air boarding-schools established to accommodate these children during their scholastic years, when I believe a high percentage would have few or no further attacks, and be launched on the world with healthy well-formed chests.—I am, etc.,

London, N.W.

C. ELAINE FIELD.

### Marriage and Parenthood

SIR,—Now that the country is becoming alive to the importance of the family unit it is time that the medical profession concerned itself more positively with the prevention of marital disharmony. There are two periods in marriage when much may be done: at the beginning and after the first child is born.

While we pay much lip service to the importance of suitably adjusted partners we do little to encourage their creation, so that far too many marriages go wrong through lack of preliminary teaching. Adequate marriage preparation—which should include the medical examination of both partners, an assessment of their psychological approach to marriage, the state of the hymen, suitable contraceptive advice when desirable, and, above all, education in technique—ought to be taken more seriously by the profession, for there can be little doubt that the seeds of much future unhappiness are often sown in the early months of marriage through ignorance and misunderstanding.

Many conditions such as dyspareunia, impotence, premature ejaculation, and frigidity could be prevented or minimized by a little helpful advice and consideration at this stage. Young people must be encouraged to seek this advice, and the doctor has both a responsibility and an opportunity for much con-

structive work in this field. More and more couples are asking for help, and yet it is no uncommon thing to find cases which are mishandled and no constructive advice is given. The assurance that all will come right in the end; the suggestion that one or other contraceptive, of which the doctor has read or heard good reports, will be an adequate safeguard; the rapid and often painful examination of the hymen or, occasionally, even the refusal to make such an examination, are neither sufficient nor helpful, and cast an unnecessary slur upon the whole profession. Over and over again one hears people say that their doctors are not interested in these matters.

After the first baby has arrived the couple have various adjustments to make. The problem of effective contraception may present itself for the first time; the resumption of coitus often needs consideration and sympathetic help; the achievement of a mutually satisfactory sex life and the emotional adjustments between mother, father, and child call for careful guidance. While much time is often spent on the problem of mother and child, little is given to those of the husband and wife. Beyond telling the woman that her sex organs have "gone back" to their normal position, that she must take care of herself and not have another child for several months, little constructive help is given. As a result many of the difficulties already enumerated develop or become accentuated. Adequately dealt with all may be well; ignored or glossed over an accumulation of difficulties may create a state of disharmony which will take longer to resolve or even become impossible to correct.

The work of probation officers, matrimonial courts, and such organizations as the Marriage Guidance Council shows conclusively that many of these conditions could have been prevented by adequate medical help and effective re-education thereby not only preventing much physical and psychological injury but saving the marriage and establishing happiness in the home instead of discord.

If the profession would take these matters more seriously and help young couples at these critical periods of their lives many marriages could be saved and the whole stability of family life strengthened. In addition, and as a preliminary to marriage preparation, we must see to it that young people both in the home and in school and youth organizations, are presented with a positive attitude to sex and marriage through effective education in the psychological, physical, and ethical aspects of sex.—I am, etc.,

London, W.1.

EDWARD F. GRIFFITH.

### Eye Signs of Anaesthesia

SIR,—I have often seen references to eye-rolling and other movements of the eyes in connexion with inhalation anaesthesia, but have never noticed any eye movements described as nystagmus. I am interested to notice in Dr. E. V. Slaughter's letter (March 25, p. 434) his observations on the development of occasional coarse oscillations.

I have had the opportunity to watch the eyes of children who are being anaesthetized in the upright position with ethyl bromide. In these cases one invariably finds that a tri-vestibular nystagmus develops just before full anaesthesia is reached. This vestibular nystagmus is almost always in the vertical plane, and the slow phase may be in either direction. Very occasionally it is slightly oblique. The eyes pass into conjugate deviation, usually in the direction of the slow phase before coming to rest in a central position, as described by your correspondent. Now, all nystagmus of a vestibular pattern must be the result of irritation of the vestibular system; hence the drug employed must irritate either the vestibular centres or tracts, the vestibular nerve, or the labyrinth itself. Skoog of Lund has shown that vestibular nystagmus can be produced by anaphylactic substance, carried direct to the vestibular centres, in the guinea-pig.

Perhaps the anaesthetists could make a careful investigation into these eye movements to see whether vestibular irritation is not apparent with all inhaled anaesthetics. This irritation must take place at a fairly constant level of anaesthesia, and I feel that there is some justification for looking on certain eye movements as an indication of the depth of anaesthesia.—I am, etc.,

Glasgow.

TOM O. HOWIE.

## Obituary

We regret to announce the death on March 26 at Weston-super-Mare of Dr. GEORGE SAMUEL POLLARD in his 85th year. He was a J.P. for the county of Somerset, had practised in Midsomer Norton and its neighbourhood for 43 years, and was a greatly esteemed member of the Bath and Bristol Branch of the B.M.A., which he joined as long ago as 1885. Dr. Pollard had his professional training at Guy's Hospital, and took the M.R.C.S.Eng. in 1882 and the L.R.C.P.Ed. in 1884, after which he was medical registrar at the Seamen's Hospital, Greenwich. He started practice at Midsomer Norton in 1885, and besides his work as a busy general practitioner he held the post of M.O.H. for the urban area and was for 23 years medical director of the Paulton Hospital. He was also medical officer to Downside Abbey and School. His many activities, professional and other, were commemorated in 1929 when a public presentation was made to him at the time of his retirement: the record is too long to be printed here; few doctors in active practice could have accomplished so much in so many directions. In the British Medical Association Dr. Pollard did good work, mainly in his own county, but many years ago he was for a time a member of the Central Council. He had held office as vice-chairman and chairman of the Bath Division and served on its executive committee. He was a member of the Bath and Bristol Branch Council for 10 years in all and president of the Branch in 1922-3. He celebrated his golden wedding in 1940, and Mrs. Pollard survives him.

Dr. ARTHUR BRIGGS DUNNE, J.P., died on March 27 at Barnby Dun, near Doncaster. He took his B.A. at Cambridge in 1891 and did not begin the study of medicine until some years afterwards. His clinical training was in Leeds and Liverpool. He qualified in 1899, took the Cambridge M.B., Ch.B. in 1902 and the D.P.H. a year later. At Leeds he won the McGill scholarship in surgery and he was called to the Bar by Lincoln's Inn. During the South African War he served as a civil surgeon with the S.A. Field Force, and after his return to England became senior resident medical officer to the City of Liverpool Isolation and Smallpox Hospital. In 1911, after a period as senior school medical officer to the City of Nottingham, he was appointed medical officer of health to the Doncaster Rural Council; in the same year he became M.O.H. for the Bentley Urban District and in 1915 for the Adwick-le-Street Urban District. In 1920 Dr. Dunne was appointed a West Riding magistrate and thereafter attended regularly on the Bench. He retired from his public health posts five years ago.

ALEXANDER ANNAND GREY CLARKE died on March 29 after a short illness at the early age of 34. He was born in India, educated at Marlborough College, and took the B.Sc.Lond. in 1929 when he was aged 19. He then proceeded to Jesus College, Oxford, where he studied forestry, but later became a medical student at St. George's Hospital. After qualification he held the post of casualty officer and house-surgeon at the hospital, took the M.B., B.S. degrees, and was commissioned as surgeon lieutenant, R.N.V.R., early in 1939. On mobilization at the outbreak of war Dr. Clarke was posted to H.M.S. *Courageous*, in which he was serving when his aircraft-carrier was torpedoed and sunk in September, 1939. He was rescued after some two hours in the sea, and subsequently senior naval officers paid tribute to his courage and devotion to duty in dealing with casualties among the survivors. A few months later Dr. Clarke developed meningitis, following recovery from which he was invalided from the Service. He then devoted himself to neurology and psychiatry, and after acting as assistant medical officer at Swansea and Littlemore (Oxford) Mental Hospitals, he took the Diploma of Psychological Medicine in 1941. Early in 1942 he was appointed medical registrar to the West End Hospital for Nervous Diseases, London, where he continued to work until his last illness. He was also an acting assistant physician to the Midday Memorial Hospital as well as to psychiatric clinics for children in the Surrey County area. Dr. C. Worster-Drought writes: Alex Grey Clarke was an ideal colleague, a loyal friend, and an enthusiastic worker. His attractive personality, his charm of manner and ready smile will be greatly missed by all his fellow-workers and his patients. He was profoundly devoted to neurology and was especially interested in the more recent therapeutics of early psychoses. Only last year (in conjunction with Dr. F. Prescott) he contributed a paper on the mental and physical manifestations of vitamin B deficiency to the *British Medical Journal*. With his far from robust constitution, the amount of time and energy Alex Clarke put into his work, as well as reading for higher examinations, without doubt lowered his resistance to the

infection which cut short a most promising career and one the medical profession could ill afford to lose.

We regret to announce the death of Dr. JAMES DUNLOP WILLIAMSON, M.D., D.L., J.P., a noted figure for many years in the medical and civic life of Belfast. Born at Aghadowey, Co. Derry, Dr. Williamson qualified in 1886 in the old Royal University of Ireland, gaining the degrees of M.D., M.Ch., M.A.O. Two years later he took up general practice in Belfast, later joining the staff of the Ulster Hospital for Children and Women, of which he remained the consulting physician till his death. His long and distinguished period of service to the City of Belfast began in 1900 when he was elected a Councillor. He became High Sheriff and in 1941 deputy Lord Mayor. He served for many years on the Public Health, Tuberculosis, and Maternity and Child Welfare Committees of the Corporation, and his interest in public health led to papers on sanitation and sewage purification. His services to Belfast were recognized when he was made a Freeman of the City a short time before his death. Dr. Williamson had been a member of the British Medical Association for 56 years.

Prof. Grey Turner writes: Dr. FRED B. LUND, who has recently died in Boston, was one of the more senior surgeons of that city, for he was born in 1865 and graduated from Harvard in 1892. For many years he had been associated with the Boston City Hospital and was well known for the work he did in connexion with that institution and his devotion to its welfare. Fred Lund was of a scholarly type and was particularly fond of the study of the history of healing. He made several contributions to the societies and the medical press on historical subjects, and his paper on "Paracelsus," which appeared in the *Annals of Surgery* for October, 1941, will remain as an evidence of his learning and interest. Just recently he informed me that once again he was reading the works of the Venerable Bede, and I looked forward to the opportunity of acting as, his guide on a long-contemplated visit to the home of that great pillar of early English learning at Jarrow-on-Tyne. He loved this country and was very happy indeed in making acquaintance with those parts of England and Scotland with which he had become familiar through our literature, and was longing to be spared to make just one further visit. Lund accompanied the Society of Clinical Surgery of America to this country in 1910 and acted as its reporter, and from then onwards he kept in friendly touch with many of the leading surgeons of Great Britain. In his home city he took a great interest in the medical societies and had been president of both the Massachusetts Medical and the Boston Surgical Societies. To the *Transactions* of these bodies he often contributed, and as a rule on some historical subject. Lund was an original Fellow of the American College of Surgeons and a member of several of the societies: he also took a great interest in the *New England Journal of Medicine*. He was a great host and loved to entertain his friends, and liked nothing better than to show visitors from this side the venerable parts of Boston, of course never forgetting the ether theatre in the Massachusetts General.

## Medical Notes in Parliament

### EDUCATION BILL

#### Medical Inspection and Treatment

In Committee on the Education Bill on March 23 the House of Commons examined Clause 46 (Medical Inspection and Treatment of Pupils). Mr. Linstead moved to add "dental and optical" where the clause referred to "medical." The country as a whole would long suffer from a shortage of dentists. There were only 650 medically qualified ophthalmic practitioners for over 5,000,000 school children. Many defects of vision were missed. That raised the question whether the services of sight-testing opticians should be used to supplement the services of the ophthalmologists. Dr. HADEN GUEST supported Mr. Linstead provided that if people not medically qualified were to make examinations this should be regarded as a provisional arrangement.

Mr. BUTLER said the school medical services would be better if there were more doctors, but they had to suffer from the needs of the Armed Forces. In many areas it was the practice for an optician to attend with the ophthalmic surgeon when children's eyes were examined. Opticians were not doctors, and he must insist that the general examination of children for eye troubles should be done by ophthalmologists and not by somebody solely concerned with the making up of prescriptions. Captain PRESCOTT said he was informed that inspection of eyes in the school was often now done by a nurse or even by a

teacher. There were 7,000 opticians and they would be of great value if employed, at least in part, for this purpose. Mr. BUTLER reaffirmed that the Ministry could not substitute opticians for ophthalmologists in important cases. They were used and would continue to be used.

Mr. Linstead withdrew his amendment.

Sir E. GRAHAM-LITTLE moved and withdrew an amendment which proposed that the Act should not be construed as imposing an obligation on any parent to submit his child to medical examination or treatment. On this Mr. Butler remarked that compulsory inspection was a novelty, but one to which he attached particular importance. He proposed and the House accepted an amendment to provide that if the parent of any pupil gave to the authority notice that he objected to the child's availing himself of any medical treatment the pupil should not be encouraged or assisted so to do.

On the motion that Clause 46 stand part of the Bill, Dr. HADEN GUEST suggested that Mr. Butler should insert later a provision that a medical inspection should be made not fewer than three times in the school career. He also asked Mr. Butler to consider the possibility of a new clause to give the school medical officer the opportunity to inspect the child's home conditions if he thought its state arose from something within the home. It was important to see that there was adequate sleeping accommodation for the child. In the course of his duties he had often unofficially entered homes and had never been refused by parents. Mr. BUTLER said the Government preferred to leave the Bill as drawn. A large majority of the children were covered in some way in the routine of inspections in a normal year before the war. The Government did not think it right to impose an extra duty on the school medical officer to go into people's homes. Under Clause 73 a school doctor could go into the home of a child having a disease so serious that it was impossible to educate the child at school.

Sir E. GRAHAM-LITTLE asked what would be the position of the family practitioner if the arrangements in this clause were carried out. If the inspection and treatment of children from 2 to 18 was to be the function of the school medical officer, without any reference to the family practitioner, an unfortunate position would arise. So great a step in the medical treatment of children should not be taken until Parliament had further knowledge of what would happen to the general health service.

The House then agreed to the clause.

#### *Position in Non-Maintained Schools*

During the continued discussion on March 28 Mr. EDE moved an amendment to Clause 73 to make arrangements by which the proprietor of any non-maintained school could secure the benefits of medical inspection and treatment. Dr. HADEN GUEST said there was no doubt that some small private schools badly needed the medical inspection and treatment, and also some public schools. He asked what steps the Board of Education proposed to take to see that there was such inspection in these schools.

Mr. EDE pointed out that the Bill gave the Board the power, for the first time, to inspect the kind of schools Dr. Haden Guest had mentioned. If they found that a school was being used, as it sometimes was, in order to object to such things as medical inspection and treatment—he was now talking of the worst types of private schools—that might be one of the items on which a report could be made by the Board. They would expect the proprietor of the school, within the limit of six months allowed, to make such arrangements as were necessary to secure the benefits of medical inspection for the pupils attending his school. Similarly, if meals were not provided where they should be, the same kind of machinery would be brought into operation. Dr. HADEN GUEST asked if it would be possible for a school to refuse to have medical inspection, and Mr. Ede replied that if it did, that might very well be a ground, under the Private Schools Clause, for bringing it before the tribunal, with a view to having the school closed. The amendment was agreed to.

#### *Vaccination*

On Clause 74 (which makes supplementary provisions with regard to medical inspection and treatment) Mr. VIANI moved an amendment to ensure that nothing in the Bill should be used for ascertaining the vaccinal condition of the children or their condition in respect of any other form of inoculation, for securing the performance of such inoculations, or for the imposition of mass radiography or any other medical procedure. He said there was considerable apprehension among many parents about the powers which were being conferred on the Board of Education in regard to medical inspection and treatment. There was nothing like unanimity of opinion, even in the medical profession, about vaccination and inoculation. Dr. HADEN GUEST expressed the hope that the Minister would not accept the amendment, which was so widely drawn that it would create considerable difficulties. Mr. MESSER expressed

the hope that the Board would consider the advisability ensuring that medical examination should include mass radiology.

Mr. EDE said that the amendment was not necessary. Nothing would be done under the clause or in the Bill to compel a child to be vaccinated or inoculated, or to undergo any of the other procedures mentioned in the amendment, without the consent of the parent. The amendment was withdrawn.

#### *Malnutrition in Occupied Countries*

The ARCHBISHOP OF CANTERBURY, in the House of Lords March 15, asked for information about the supply of food enemy-occupied countries. He said that what had been done in Greece had probably saved the lives of 2,000,000 people. He proposed that in Belgium the Allies should supply the medical requirements to prevent serious deterioration of health. He understood that vitamins were treated as medical supplies, and that it was possible to pass them through, whereas dried milk was treated as food. In Poland it seemed that children up to the age of 3 were tolerably well fed, in order that they might be German citizens in future. In Greece 1,800,000 children needed swift help; in Holland about 300,000; in Poland 3,500,000; in Czechoslovakia 1,600,000; in Yugoslavia 2,100,000. These were figures for young children.

Lord HORDER said clinical examination of refugees reaching this country or Lisbon showed conditions only produced by prolonged malnutrition, including hunger oedemas. The calorific value of a day's food required for health was 2,480. In September, 1943, the basic daily ration in Belgium was about 1,260 calories—about half the ration in that country during the war of 1914-18. In France the calorific value at the end of 1943 was about 1,080. Children in Belgium under 6 years received supplements. These were withdrawn at 6. Adolescents from 14 to 21 were suffering most. Adults, according to a large investigation of the Liège Polytechnic, had lost 20 to 34 lb. weight, and protein substances in the blood showed a fall of from 20 to 50%. Pregnant women showed a drop of 80% in the normal weight gain, and infants at birth an average drop in weight of 2.2 lb. Students, nurses, and hospital personnel showed malnutrition. In Belgium, between December, 1941, and February, 1943, the rise in the incidence of tuberculosis was 58.5%. Fulminating pulmonary tuberculosis was to-day experienced in Belgium, France, and Greece. He understood the Nazis had not prevented the food supplies sent to Greece from reaching the people for whom they were intended. Why not try elsewhere?

The EARL OF SELBORNE, replying for the Government, said that the Government had endeavoured to mitigate the effect of the blockade to its allies. It had taken vitamin D off the contraband list. Occupied Europe was one economic unit and was worked by the Germans as such. Therefore he knew no reason why relief should be confined to Belgium. In that country in 1914 the death rate per 1,000 was 14.14. By 1918 it was 20.82. In 1939 it was 14.14; in 1942 it was 14.3. For the first half of 1943 deaths were at the rate of 13.0 per 1,000, although the Germans had deported the strongest and healthiest section of the community. In 1929 the infant mortality rate in Belgium was 104 per 1,000; in 1939, 73 per 1,000; and in 1942, 78. It was impossible for anybody in Europe, or in any other country, to control the distribution of food to necessitous cases. Could a reasonable man doubt that the Germans would avail themselves of the amount of food going into a country in order to manipulate the basic ration so that the benefit of the imported food rebounded to them? Allied experience in Greece had not been such as to encourage the British Government to think that control of that kind would be easy to administer in other parts of occupied Europe. But if circumstances allowed the British Government to mitigate the lot of its allies without injuring its war effort, it would gladly take advantage of the opportunity.

#### *Maternity Accommodation*

Mr. WILLINK stated, in the course of a reply on March 30, that in 1938 there had been in England and Wales 11,500 maternity beds. To-day there were 15,500 and also 2,500 emergency maternity beds. In addition, 500 other beds had been approved. The beds available before the war took approximately one-third of the births. Those at present available took one-half of them. That was equal roughly to the all-over increase in demand.

#### *Serving Doctors' Practice Losses*

On April 4 Sir E. GRAHAM-LITTLE asked the Secretary of State for War if he was aware that many doctors on joining the Forces in 1939 lost their practices which, in many cases, they had purchased with the aid of loans, charges on which they had to meet out of Service pay; and if he would give an assurance that in such cases compensation would be paid after the war equal to the pre-war value of their practices. Sir

IN ANDERSON, who replied, said: Losses of this nature affect many different sections of the community are among the stressing consequences of a war such as that in which we are now engaged, and I clearly could not single out one particular class of case for exceptional treatment in the manner proposed.

#### Increase in Illness among Women Civil Servants

On April 4 Mr. BARTLETT asked the Secretary to the Treasury what extent information in his possession corresponded with the common experience of medical practitioners that there had recently been an increase of illness among women civil servants due to fatigue; and whether he would be prepared to authorize heads of Departments to exercise discretion in suitable cases for the reduction of hours in modification of instructions given at a time when the national crisis was in its most acute stage. Mr. ASHETON: Owing to shortage of staff complete annual sick rate returns for the Civil Service are not available. Such information as I have shows definite increase in sick absence over pre-war rates, and on the whole greater increase for women than for men, but the increase varies in different sections and localities, and is not, over all, very great. Heads of Departments have discretion in regard to hours, but, in view of the acute and increasing man-power shortage, they are not able to reduce hours generally.

#### Notes in Brief

Mr. Peat stated on March 2 that during recent weeks there had been a substantial increase in the supply of sulphathiazole available or civilian use. Production should now be adequate to enable all prescriptions to be met. It was now available, on a prescription, to everybody.

Mr. Willink proposes to issue a summary report of the Ministry of Health for the year ending March 31, 1944, but is unable at present to indicate the date.

The number of doctors in the *Medical Register* at the end of last year was 71,882. This figure includes many who are not normally resident in the United Kingdom or who have retired from practice, as well as those registered, temporarily or otherwise, by virtue of Empire or foreign qualifications.

In the House of Lords on March 1 the Income Tax (Offices and Employments) Bill and the Disabled Persons (Employment) Bill received the Royal Assent.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In England and Wales notifications of measles and whooping-cough showed the greatest fluctuations, with totals higher than last week's by 531 and 218 respectively.

The rise in whooping-cough was general throughout the country, but was especially marked in Essex and Flint, where the total notifications exceeded those of last week by 31 and 24. The increase in measles was most noticeable in the south, especially in Kent, Isle of Wight, London, and Sussex, whose total notifications exceeded those of last week by 111, 84, 77, and 35 respectively. Durham also recorded a big rise—47—over last week's total. In Lancashire the notifications of measles dropped by 64. The total notifications of cerebrospinal fever were 14 more than last week, and the incidence of this disease is at its highest level for the past year.

There were 5 more cases of dysentery: during the past seven weeks the notifications have averaged 243 per week. The largest returns were those of Lancashire 62, London 32, Derbyshire 32, Surrey 26, Middlesex 16, Essex 11, Yorks West Riding 10.

Two cases of smallpox have been reported in Pudsey, Yorkshire.

In Scotland there were rises of 19, 32, and 34 in the total incidence of dysentery, measles, and scarlet fever, but a fall in incidence was reported for whooping-cough 26, and diphtheria 13. The 136 cases of dysentery were only 5 below the very high total of six weeks ago. The largest returns were: Lanark County 36, Glasgow 36, Edinburgh 15, Dumfries County 15, Dundee 12. The only large local variations in the incidence of measles were increases in the towns of Greenock of 35, and Paisley of 26, and a decrease in Glasgow of 33.

In Eire rises in the notifications of diphtheria by 24, and of measles by 78, were recorded. The rise was general throughout the country except in Dublin C.B., where measles declined by 37 cases.

### Week Ending April 1

The returns of infectious diseases in England and Wales during the week included: scarlet fever 2,450, whooping-cough 2,141, diphtheria 724, measles 2,643, acute pneumonia 1,277, cerebrospinal fever 86, dysentery 309, paratyphoid 0, typhoid 5, smallpox 1. Deaths from influenza numbered 32.

No. 12

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 25.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or not return available.

\* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

## The Services

A meeting of the subscribers of the Naval Medical Compassionate Fund will be held on Friday, April 28, at 3 p.m., at the Medical Department of the Navy, 64, St. James's Street, London, S.W., to elect six Directors of the Fund.

The *London Gazette* has announced the appointment as M.B.E. (Military Division) of Capt. S. D. Stock, R.A.M.C., in recognition of gallant conduct in carrying out hazardous work in a very brave manner.

### CASUALTIES IN THE MEDICAL SERVICES

*Wounded.*—Temp. Lieut.-Col. G. S. N. Hughes, I.M.S.; War Subs. Capt. J. W. R. Battram, R. A. S. Gibb, B. C. M. Palmer, R.A.M.C.

*Prisoners of war.*—Temp. Major P. V. MacGarry, R.A.M.C.; Acting Major E. L. Ellis, R.A.M.C.; War Subs. Capt. J. E. A. Bartlett, D. Benson, C. F. Campbell, G. M. Davies, T. E. Marshall, C. R. Robson, and R. D. Taylor, R.A.M.C.; Lieut. J. Markowitz, R.A.M.C.

*Died on active service.*—Lieut.-Col. F. A. Roddy, R.A.M.C.

## Universities and Colleges

### UNIVERSITY OF EDINBURGH

#### Chair of Public Health

As briefly announced in the *Journal* of April 1 the University Court has appointed to the Bruce and John Usher Chair of Public Health Prof. F. A. E. Crew, M.D., D.Sc., F.R.C.P.Ed., F.R.S., in succession to Prof. P. S. Lelcan. Since 1928 Prof. Crew has occupied the Chair of Animal Genetics; in recent years he has devoted attention to the problems of social biology and social medicine, and his appointment to the Bruce and John Usher Chair marks an important new development in medical teaching and research in Edinburgh.

For many years after the Public Health Services became an established feature of national administration, the orientation of these services was mainly towards prevention of the specific infectious diseases, and the teaching of public health in the medical schools became centred on environmental hygiene and the control of infection. While the medical undergraduate must be taught the elements of these subjects, instruction in the technicalities of public health practice is a subject for postgraduate study, and in recent years the need for a different approach to the study of health in the undergraduate curriculum has been appreciated. The developments in the health services forecast in the Government White Paper indicate that medicine must play an ever-increasing part in the future social life of the people, and a new outlook has emerged under the designation Social Medicine. It is not enough to protect the public individually and collectively against the epidemic diseases, but health of body and mind must be created and preserved by all possible means. Many adverse factors in modern society, particularly among the industrial population, are playing a tremendous part both directly and indirectly in causing ill-health and unfitness. Advances in knowledge of nutrition in relation to social conditions have revealed certain of these factors. The facts recently brought to light on infant mortality in Scotland are a tragic reminder of the existence of such adverse conditions in the social life of the people.

In the future medical curriculum in Edinburgh it is proposed to develop the teaching of these aspects of medicine—namely, social biology, social medicine, and positive health. The task of developing such teaching has been entrusted to Prof. Crew, who will bring to his future academic work a wide knowledge of biological science, on the principles of which all health studies must be based, and a deep interest in the problems of social biology and medicine. Along with this new teaching on health the undergraduate will receive instruction as before in the elements of environmental hygiene, public sanitation, and the control of communicable diseases. By arrangement between the University and the Corporation of Edinburgh, the Medical Officer of Health, Dr. W. G. Clark, and the staff of the Public Health Department of the City will undertake the main part of this teaching in co-operation with the new professor; and in the postgraduate curriculum for the D.P.H., Dr. Clark and his staff will be responsible for all the technical instruction in public health practice and administration. The teaching to be undertaken by Prof. Crew and that of Dr. Clark will be complementary, and both courses together will form the basis of future teaching in Edinburgh in the wide field of health and social medicine. In creating and developing this University School of Health other academic departments will contribute, such as those of Child Life and Health, Tuberculosis, Psychiatry, Social Study.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS

At a meeting of the Royal Faculty of Physicians and Surgeons Glasgow held on April 3, the President, Dr. James H. MacDonn, in the chair, the following were admitted Fellows of Faculty (Physician): W. S. Bell, M.B., T. G. Brown, M.B., D.P.H., P. Peacock, M.B., W. N. Rogers, M.D., W. T. Strauss, M.D.

The following were admitted Fellows of Faculty *qua* Surgeon G. B. Mair, F.R.C.S.Ed., G. H. Stevenson, F.R.C.S.Ed.

## Medical News

The London Jewish Hospital Medical Society and the Jewish Emergency Medical and Dental Association will show a film entitled "Red Army Medical Service" in the Hastings Hall at B.M. House, Tavistock Square, W.C., on Sunday, April 16, at 3 p.m. Speakers: Prof. S. Sarkisov (Russia), Prof. Samson Wright, and Mr. Ingram Lindner.

A meeting of the London Association of the Medical Women's Federation will be held at 26, Portland Place, W.1, on Tuesday, April 18, at 7.45 p.m., when Dr. Neville Goodman will speak on "Problems of Health in Europe." Medical guests are invited. A meeting on the White Paper is being arranged for May.

The British Institute of Radiology will hold a meeting of medical members in the Reid-Knox Hall, 32, Welbeck Street, London, W.1, on Friday, April 21, at 2.30 p.m. On April 22 at the same hour Dr. J. Blair Hartley will read a paper on "The Future of Radiology in Obstetrics."

A Diagnosis Section meeting of the Faculty of Radiologists will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, W.C., on Saturday, April 22, at 10.30 a.m., when papers will be given by Major D. C. Eaglesham, R.C.A.M.C., on "Observations on Opaque Myelography of Lumbo-sacral Disk Herniations," and Dr. A. M. Raekow on "Some Problems of Appendix Radiology," to be followed by a discussion.

The Food Education Society will meet on Monday, April 24, at 3 p.m. at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., to hear a public lecture on "Food and the Teeth" by Sir Norman Bennett.

The spring meeting of the British Orthopaedic Association will be held in Leeds on Friday and Saturday, May 12 and 13. The morning session (9.15 a.m.) on Friday—to be held in the Physiology Lecture Theatre at the Medical School—will be devoted to papers read by Leeds men. In the afternoon (2 p.m.) there will be a clinical demonstration at the Infirmary by members of the staff. On Saturday (9.15 a.m.)—again in the Physiology Lecture Theatre—a business meeting will be followed by the reading of short papers by medical officers in the American and British Armies.

There has been formed a Polish Medical Association in the United Kingdom with its seat in London. At a general meeting held on March 26 in the Great Hall of B.M.A. House, to which about 400 Polish doctors now in this country were invited, the following were elected: Hon. President, Dr. George de Swiet; Chairman of Council, Dr. C. Meissner; Secretary, Dr. B. Jedlewski. The address of this organization is B.M.A. House, Tavistock Square, W.C.1.

The Council of Management of Preston Hall, British Legion Village, Maidstone, Kent, has appointed Dr. J. Douglas Robertson D.Sc., Ph.D., M.R.C.P., F.R.S.Ed., as clinical pathologist to the British Legion sanatoria, and Mr. A. T. Fripp, F.R.C.S., as visiting orthopaedic surgeon in connexion with the new wing at Nayland Sanatorium, which will accept female patients with non-pulmonary conditions for treatment.

Major Sir Brunel Cohen has given £1,000 towards the cost of a x-ray unit at Nayland Sanatorium which was taken over by the British Legion on May 1, 1943. It is proposed to establish the unit in the new treatment centre which will be built as soon as permission is obtained for its erection. Sir Brunel Cohen has for long been identified with the work of the British Legion in this country, is Treasurer of the British Legion, a former Member of Parliament and himself a severely disabled ex-Service officer from the last war.

Lord Nuffield and the Trustees of the Nuffield Foundation have authorized grants amounting to approximately £9,000 to the Potato Research Scheme. The production of varieties resistant to disease is work of the highest importance to this country, and other countries in the Empire need varieties suited to their conditions. Scientific work has shown that these diverse qualities desired must be sought among potatoes indigenous to Central and South America. A very large collection of such types, wild and cultivated, has been formed at the School of Agriculture, Cambridge, and scientific investigation of them started.

## Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Antology Western*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 3353. TELEGRAMS: *Articulate Western*, London.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisera Western*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumshugh Gardens, Edinburgh

### ANY QUESTIONS?

#### More about the Rh Factor

**Q.**—I have a patient aged 30 whose first child was normal in all respects. Her second baby died of haemolytic disease of the newborn. She was advised by her doctor at that time not to have any more children. She is keen to have another child, and I feel that there is an even chance of its being born normal, and should it show any signs of haemolytic disease it stands a very good chance of survival as a result of recent advances in our knowledge. What advice should I give?

**A.**—If the father is heterozygous (Rh<sup>rh</sup>) there should be an equal chance that any subsequent pregnancy will produce an Rh-negative normal baby, although the birth of a normal child immediately after one suffering from haemolytic disease is said to be uncommon. If the father is homozygous (Rh<sup>rh</sup>) every child born subsequently will be affected; the first child was normal because the mother had not then developed sufficient anti-Rh agglutinins to produce haemolysis. Help in determining the genotype of the father may be obtained by testing their child, since, if it is Rh-negative, the father must be heterozygous. If, however, the child is Rh-positive, further help can be obtained by determining the father's Rh subgroup: this St serum agglutinates the red cells of 80% of people, including all negative people and all those (48%) who are heterozygous; therefore the remaining 20% of people whose red cells are not agglutinated must be homozygous (see article by G. L. Taylor and R. R. Race in the *Journal* of Feb. 26, p. 228). Actually, since 38% of people are homozygous this test will discover over half of them, but it can be carried out in only a few laboratories.

Should the parents have another child and it develops haemolytic disease of the newborn, the immediate prognosis would be a good one if the child were given prompt and adequate transfusions with Rh-negative blood, but we do not yet know whether such treatment will prevent the occurrence of kernicterus or cirrhosis of the liver. In previous years, when regard was paid only to ABO grouping, kernicterus occurred in about 8% of cases; but evidence should be forthcoming in 2 or 3 years' time to show whether this incidence is diminished by the use of Rh-negative blood. The possibility that the child may develop kernicterus or cirrhosis must be clearly understood by the parents should they decide to have another child, but the risk that haemolytic disease may manifest itself as hydrops foetalis is so small that it can be disregarded.

#### Oiling Blankets

**Q.**—May I have details of the technique of oiling blankets to prevent the disturbance of fluff, dust, etc., or alternatively a reference where this is given? What I have in view is avoiding such contamination of the air in the operating theatre.

**A.**—Recent work has shown that blankets may be grossly contaminated by droplets expelled by streptococcal and staphylococcal throat and nose carriers, and that, during bed-making or when the bed is merely being tidied, the dried bacteria-containing droplets are raised into the air and may produce infection by inhalation or by falling on susceptible tissues such as open wounds or burns. A contaminated blanket brought into the operating theatre with a patient may therefore be a means of infecting intentional wounds. The fluff of blankets is also the chief contributor to the dust of hospital wards. Van den Ende and his colleagues (*Lancet*, 1941, 1, 716) had found that spindle oil, a crude liquid paraffin, could when rubbed into wooden or lino-covered floors prevent bacteria-infected dust being raised into the air during sweeping. This principle was applied to textiles, at first using purified liquid paraffin in white spirit, and later "technical white oil" with an emulsifying agent which allowed an oil-in-water mixture. Recipes for the preparation of these oil emulsions may be found in the report by van den Ende and Thomas (*Lancet*, 1941, 2, 755); a ready-made oil emulsion, olinol No. 1, is available from the Manchester Oil Refinery Ltd.

In practice 20% of the oil emulsion is added to the last cold-water rinse in the washing machine. The blankets are treated for 20 minutes, when they are transferred to the hydro-extractor, from which the oil-in-water effluent may be salvaged for further use. Though they now contain 3 to 5% of oil, the treated blankets can scarcely be differentiated from unoiled blankets. Besides the physical adsorption of dust particles, the oiled blankets may, depending on the emulsifying agent, be bactericidal as well as bacteria in moist droplets. In any case the oiling of blankets and other textiles will reduce by 99% the number of bacteria liberated during vigorous shaking. Blankets in constant use need to be re-oiled once a month, but not necessarily after sterilization, which, incidentally, should be done at a pressure not exceeding 5 lb. in order to avoid damage to the wool. Further technical improvements will doubtless increase the practicability of using oiled bed-linen for preventing dust-borne infection.

#### Fore and Aft

**Q.**—What are the modern views on the relation (if any exists) between the pelvic viscera or the abdominal contents and the pharynx and its accessory structures? Some thirty years ago, when I was a student, we used to be told about a "prostatic cough," due, I understood, to some kind of influence of an enlarged prostate on the cough mechanism. I have also seen references to a similar cough produced by some uterine conditions, and to "fullness in the head," rushing and roaring noises in the ears, and other slight but not necessarily insignificant symptoms produced by distension of the colon and other forms of constipation. Is all this imaginary or subjective, or has any anatomical connexion, conceivably by way of the circulatory system or the autonomic nervous system, been demonstrated between the pelvic viscera or the abdominal contents and (a) the cough mechanism or (b) the ear and its accessory structures? Or perhaps one might put it: Has any anatomical connexion been demonstrated between the upper and lower ends of the alimentary canal and their accessory structures?

**A.**—No special connexion of the kind is known. Cough is not a common symptom of prostatic disease, and it would suggest that the lesion had led to uraemia. Widespread effects may be produced by distension of the rectum—salivation, nausea and vomiting, mental depression, restlessness, mental haziness, and inability to concentrate. The power of ocular accommodation may be reduced, and measurable changes such as distension of veins and oedema have been described in the retina. These effects show that the rectum is an unusually sensitive organ, and that when it is stimulated a strong stream of impulses flows into the central nervous system and radiates over a considerable area. Sudden death has occurred from distension of the uterus with bland fluid in the attempt to produce abortion. All this indicates that reflex disturbances occur when the pelvic viscera are stimulated, but it does not indicate any special anatomical connexions. An endocrine relationship appears to exist between the nasal mucosa and the sexual organs. Female monkeys show a cyclical activity of the nasal mucosa which is synchronous with the periodic swelling of the sexual skin, and oestrogens have been used in the treatment of atrophic rhinitis. This relationship has some bearing on the phenomenon of vicarious menstruation.

#### Pregnancy and Tuberculous Spine

**Q.**—Is it advisable for a woman aged 32 years, who had tuberculosis of the spine, to marry? And if so, is it advisable for her to have a child? The person concerned was regarded as "cured" about twelve years ago. What is the probability of a recurrence under normal living conditions? Is either of the above factors likely to have any effect in increasing probability?

**A.**—There is undoubtedly a tendency for bone tuberculosis to become active during pregnancy. I know of a case of tuberculosis of the dorsal vertebrae, treated by bone graft some years previously, in which a fatal miliary tuberculosis developed at the end of pregnancy; and I have hearsay knowledge of three other somewhat similar cases. On the other hand, there are many examples of women with old-standing Pott's disease of the spine who have passed uneventfully through pregnancy and the puerperium. Much depends upon the time that has elapsed since there has been clinical or radiological evidence of active disease. To forbid pregnancy in every circumstance will cause needless unhappiness and may lead the patient to feel that her mission in life has remained unfulfilled. On the other hand, to ignore the danger is equally reprehensible. In this case, if twelve years have elapsed since there was evidence of activity (this should include radiological examination), it seems reasonable to allow a pregnancy, other things being equal. The patient must be made to realize the paramount importance of regular adequate rest and of good diet during her pregnancy; milk intake should be specially liberal in order to prevent a possible fall in blood calcium.

The above remarks must be taken only as a general guide. Without full knowledge of the patient, her general condition, her personal circumstances, and so forth, it is not possible to give either a plain "Yes!" or an emphatic "No!"

**Puerperal Fever and Streptococci**

**Q.**—It has usually been supposed that a case of scarlet fever in a household constitutes a danger to a woman who is about to be or has been confined in that household, because of the danger of puerperal fever. Is there any evidence that the causative haemolytic streptococcus in puerperal fever is in fact one of the types causing scarlet fever? It has been suggested that the response to sulphanilamide treatment in puerperal fever and the lack of response to such treatment in scarlet fever indicates a difference in the causative organism.

**A.**—There is no doubt that any haemolytic streptococcus causing scarlet fever or streptococcal tonsillitis is capable, given the opportunity, of producing infection in the genital tract of a parturient woman. The common scarlatinal strains—Griffith's Types 1, 2, 3, and 4—have all been isolated from cases of puerperal infection, and, of course, some of the affected patients develop scarlatinal rashes. Therefore, when a woman acquires a streptococcal puerperal infection, inquiry should be made about any sore throats in the household, and all family contacts as well as the attendant midwife or doctor should have nose and throat swabs examined for haemolytic streptococci.

The failure of scarlet fever to respond to sulphonamide therapy is due to the fact that it is essentially a toxæmia accompanying a local throat infection, whereas puerperal sepsis is an invasive infection of the uterus by the haemolytic streptococcus, and this type of streptococcal infection (compare, for example, erysipelas) is particularly amenable to treatment with sulphanilamide.

**Vaccination and Encephalitis**

**Q.**—Is there any danger in revaccinating young adults? Was there not a scare some years ago when several cases of encephalitis followed revaccination? Is this danger great? How can it be avoided?

**A.**—Encephalitis is a very rare complication of vaccinia. The Committee on Vaccination (1928) reported an incidence in England of 1 : 48,000, and in Glasgow during 1942, when about half a million persons were vaccinated, the incidence was approximately 1 : 70,000. It occurs almost entirely after primary vaccination, although 1 of the 7 Glasgow cases recorded by Anderson and MacKenzie (*Lancet*, 1942, 2, 667) was a woman aged 41 who had been successfully vaccinated in infancy. Children over 5 and young adults are the age groups principally affected. There is no evidence that the encephalitis is associated with any special batch or preparation of lymph. Its greater frequency in England and Holland from 1923 to 1928 suggests that there may be a certain epidemicity in its occurrence. No conclusion has been reached as to whether the encephalitis is caused by the original virus—it follows other virus infections, particularly measles and mumps—or is due to the activation of a latent virus. Symptoms, varying from severe headache and drowsiness to deep coma, usually develop within 7 to 14 days after vaccination, and recovery, when it occurs, seems to be complete without sequels. Convalescent serum or antivaccinal horse serum may be used for the treatment of severe infections. Avoidance of the complication can best be effected by avoiding primary vaccination in school-children and adolescents. If this is impossible, a single linear insertion instead of multiple insertions should be carried out in such cases.

**Atrophic Rhinitis**

**Q.**—A man of about 40 has had atrophic rhinitis for the past 20 years. I would be grateful for suggestions regarding treatment.

**A.**—The most satisfactory local application is glycerin containing 25% of glucose. Benians showed that the organism associated with atrophic rhinitis does not grow in carbohydrate, which encourages the growth of the harmless *Staphylococcus albus*. This answers well when applied in practice, but crusts should be removed.

**Trichomonas vaginalis**

**Q.**—Is infection by *Trichomonas vaginalis* becoming more common? How is it usually acquired? Is it limited to the vagina in females? Are male subjects liable to infection? How is it recognized? What is the best treatment?

**A.**—There is no doubt that infestation by *Trichomonas vaginalis* is either becoming much more common or is being diagnosed more frequently. It seems probable that gynaecologists and venereologists are on the lookout for it much more nowadays than formerly. It is not known how it is acquired, but some regard it as venereal in origin. Apparently it is often present in the normal vagina, but gives rise to symptoms mainly when the pH is about 6 (normal 4-5). It is usually limited to the vagina in females, but may affect other parts of the urogenital tract, especially the urethra. Males are liable to infestation, but the condition is either not common or rarely gives rise to symptoms.

Lister and Lees found *Trichomonas vaginalis* in 4% of 400 consecutive cases (excluding syphilis) attending a V.D. out-patient department and in 16% of 105 cases of diseases of the genito-urinary

system (excluding gonorrhoea). The diagnosis depends on demonstration of the organism. This is done by means of microscopic examination of: (a) moist films, preferably with the dark-ground microscope; (b) cultures; (c) films stained by Leishman's method. The first is probably the most satisfactory method for anyone but an expert.

Treatment consists in producing conditions unsuitable for the growth of the organism. In the male alkalization of the urine by means of sodium bicarbonate by mouth often suffices, but in female various other methods are usually required. These include silver picrate in the form of powder for insufflation and pessaries; tablets of pentavalent arsenic for insertion in the vagina, combined with alkaline douches, or "negatol" in the strength of 2½% for douche and 100% for painting.

**Eczema in a Child**

**Q.**—What treatment can be given either locally or generally to a child of 2½ years suffering from eczema? The lesions are present on the flexor aspect of both legs (in popliteal space), and also on the flexor aspect of elbows and wrists. Lesions are areas of redness and at times covered with scales, at present dry. Various ointments have been tried without any success. The child is well fed, looks well, and has no other defects.

**A.**—The variety of eczema described is met with in children of an allergic disposition. General treatment recognizes their highly strung make-up and aims at a placid environment. Cod-liver oil may be given with advantage, and in many cases residence by the sea, and, in suitable weather, sea bathing, are beneficial. A 6% crude coal-tar paste is usually well tolerated, but should be employed only for a limited time. In view of the nervous make-up, attempts at desensitization are best avoided.

**LETTERS, NOTES, ETC.****Thumb-sucking**

Mr. W. STUART THOMSON, L.D.S., L.R.C.P.Ed. (Edinburgh), writes: With reference to the treatment suggested for the habit of thumb-sucking in your issue of Feb. 19 (p. 277), I should like to criticize very strongly the advice that the child be given a sweet to chew before going to sleep. I quite appreciate that our knowledge of the cause of dental caries is incomplete. Nevertheless, I believe that the large majority of dental surgeons who have studied this subject are agreed that the principal activating cause (or even sole activating cause) of dental caries is the lodgment of fermentable carbohydrate around the teeth. The very worst possible time for carbohydrate to be lodged around the teeth is when the subject is asleep and Nature's cleansing mechanism is at a minimum. Need I say more except to admit that I regret I am unable to offer a suitable substitute for the bedtime sweet?

**Treatment of Sciatica**

Dr. E. BRAUER writes from Spennymoor, Co. Durham: With great interest I have read Sir Arthur Hurst's article on the treatment of sciatica. To the measures enumerated, however, I would like to add one which I have employed with a very high degree of success indeed. It is that of vitamin B<sub>12</sub> injections. I have given vitamin B<sub>12</sub> in all cases of what I diagnosed as neuritis—facial, intercostal, etc.—and, since I regarded sciatica, correctly or not, as neuritis I have used it for this condition as well. I have given it near or far away from the painful region, in the arm or leg, and have nearly always seen good results. Such results, I think, are more than simply due to faith in the treatment; owing to very poor facilities in this area for physical therapy, such as radiant heat, etc. I have not combined this treatment with any of these measures, so that the results cannot be attributed to them. Nor did I make the patient usually rest in bed, except in very severe cases and then only for 2 to 3 days. The results were very rapid, and the patient were fit for work within a fortnight to 4 weeks from the onset of the sciatica. I believe that all cases of what I might call idiopathic sciatica respond to vitamin B<sub>12</sub> therapy; those which showed no improvement at all I regarded as due to causes mentioned by Sir Arthur Hurst, such as prolapse of the nucleus pulposus, etc. I must mention that I find vitamin B<sub>12</sub> in the treatment of neuritis only effective when given parenterally. If given by the mouth the active antineuritic principle seems to be very much diminished or not almost lost in the alimentary canal. To obtain quicker results I have recently used the concentrated ampoules of 25 mg. per c.cm giving 3 to 6 injections daily or on alternate days.

**Infectious Jaundice: A Correction**

Dr. A. M. McFARLAN writes: I find that in your issue of April your report of the discussion on the aetiology of infectious jaundice quotes me as having said: "The laboratory studies included various examinations which excluded the possibility that it was an outbreak of virus disease." This is of course nonsense, and I can only suppose that your reporter misheard what I said about examination excluding Weil's disease and common bacteriological infections of respiratory or alimentary tracts.

LONDON SATURDAY APRIL 22 1944

## THE AETIOLOGY OF POST-ARSPHENAMINE JAUNDICE

BY

J. BEATTIE, M.D., D.Sc.  
*Bernhard Baron Professor. R.C.S.*

AND

J. MARSHALL, M.B., M.R.C.S.  
*Major. R.A.M.C.*

(From the Bernhard Baron Research Laboratories, Royal College of Surgeons of England)

Damage to the liver parenchyma, with or without icterus, can occur at any stage of untreated syphilis, acquired or prenatal. Icterus is rare in early acquired syphilis, and when it appears is usually coincident with secondary manifestations, original or relapse. The liver biopsy findings in cases of jaundice in untreated secondary syphilis are indistinguishable from those seen in cases of post-arsphenamine jaundice. Liver material from untreated secondary syphilitics who show no clinical signs of liver damage is quite normal. Jaundice in untreated cases, though of some interest, is of less importance than the icterus which appears after arsenical treatment has been started. This type of jaundice, frequently referred to as "post-arsphenamine jaundice," differs from the jaundice of untreated early syphilis in certain respects. In the latter type the use of arsphenamines in treatment is, in our experience, without danger and leads to a rapid clearing of the icterus. This is not so in the case of post-arsphenamine jaundice. Although many cases have been described in which arsenical treatment has been continued through post-arsphenamine jaundice, we are convinced that such a policy is dangerous. The administration of arsenic before clinical and biochemical recovery in some such cases has produced alarming evidence of increased liver damage. Milian (1934), who believed that the delayed jaundice of arsphenamine treatment is due not to the drug but to a hepatic recurrence of syphilis, continued to treat 75 cases with arsphenamine, and claimed satisfactory results in 66. Of the remainder, 11 were intolerant and 4 died.

Goodman and Gilman (1941) thought that jaundice during arsphenamine treatment "may be due to one or a combination of the following factors—the drug, syphilis itself, or intercurrent infection. The evidence is convincing that many cases represent attacks of non-specific catarrhal jaundice occurring in patients whose livers are subjected to the added insults of syphilis and an arsenical." Mitchell (1943), reporting on jaundice in syphilitics under treatment in the Canadian Army in Great Britain, suggested that jaundice is due to "the association of two hepatotoxic agents—the arsenic and the agent or toxin of infectious hepatitis in patients under arsenotherapy." These two opinions imply that the infectious hepatitis or non-specific catarrhal jaundice (other synonyms—toxic hepatitis, non-spirochaetal epidemic jaundice, simple jaundice, acute catarrhal jaundice) associated with arsenical treatment in syphilitics is identical with that which produces jaundice so frequently in the normal population and which has become so prevalent in recent years.

### Two Types of Hepatitis

It is necessary to emphasize the fact that there are apparently two types of hepatitis occurring during arsenical therapy: (a) an early type which is usually mild and appears within the first two weeks after the first injection of the drug has been given; and (b) a late type which may appear at a variable time after starting treatment, but usually becomes obvious between the 12th and 17th weeks of treatment.

The early type is most commonly seen in intensive arsenotherapy (five-day or twenty-day), but it can occur during the standard treatment course of weekly or bi-weekly injections of an arsenical. The manifestations vary from an increase of urobilinogen excretion to a slight degree of actual icterus of conjunctivae or skin, but are always short-lived. It has been suggested that the cause of this condition may be a direct arsenical damage of the capillaries somewhat analogous to that found in haemorrhagic encephalitis following intensive arsenical treatment. The late type usually appears, as has been stated above, between 12 and 17 weeks after the initiation of arsenical treatment, whether by the intensive or the standard methods.

The pathological pictures and laboratory findings in these two types are different. In the early type there is an increase in the total blood cholesterol, cholesterol esters, and blood phosphates, with "bile thrombi" and cholangiolitis in liver biopsy specimens (Gutman and Hanger, 1941; Naunyn, 1919). The late type shows a marked alteration in the liver cells, ranging from swelling to necrosis with varying degrees of fibrosis (Dible and McMichael, 1943; Dible, McMichael, and Sherlock, 1943). The serum bilirubin values are higher than normal, and may be as high as 49.5 mg. per 100 ml. (in a non-fatal case in our series).

The type with which we are here concerned is the late or delayed type of jaundice which occurs in patients suffering from early syphilis who are being treated with neoarsphenamine by the routine British Army method. This anti-syphilitic treatment consists of weekly injections of 0.6 g. of neoarsphenamine for ten weeks, followed by an interval of four weeks, when a similar second course is given. Third and fourth courses of treatment are given, but a four-weeks rest is interposed between each two treatment courses.

### Syphilis and Arsenicals as Causal Factors

The three factors which Goodman and Gilman (1941) suggest as being responsible, either singly or in combination, for post-arsphenamine jaundice are syphilis, the arsenicals, and an attack of non-specific catarrhal jaundice. There is no pathological evidence to support Milian's view that the delayed jaundice of the type under consideration is due to syphilis of the liver (Dible and McMichael, 1943). The organic arsenicals used in the treatment of syphilis are, however, hepatotoxic. They can produce liver damage in experimental animals, and are almost certainly responsible for the early type of jaundice occurring in intensive arsenical treatment (Lloyd Jones and Maitland, 1943). If they were solely responsible for post-arsphenamine jaundice it might be expected that the incidence of jaundice would remain fairly uniform from year to year. Before the war and up to the spring of 1941 the experience of one of us (J. M.) in clinic practice showed that the incidence of jaundice was about 2 per 100 new cases of early syphilis under treatment. Although there was no change in the scheme of treatment, dosage, type, and manufacturers of the drug, the

incidence rose steadily during 1941 and 1942, until in one clinic (M.I.H.) 46% of treated cases developed jaundice.

The possibility that owing to wartime conditions there might have been some alteration in the toxicity of the drug used was considered. This hypothesis was discarded early when it was discovered that other clinics whose jaundice incidence was lower were using the same drugs and in some cases the same batches of drugs from the same manufacturer. Drugs from different manufacturers and different batches of the same drug were tried in this clinic, but the incidence was not significantly affected whatever drug or batch was used. As Curtis (1942) had observed that an increase in the amount of drug used (from 7.5 to 13 g. in thirteen weeks) increased the jaundice incidence from 7-8% to 25-30%, it was thought that a reduction in the dose of arsenical from 5.85 g. to 4.05 g. over a period of ten weeks might show a significant decrease in incidence. In certain clinics where the reduced dosage was used no such decrease was observed during an adequate period of observation. When arsenoxide was given by bi-weekly injection instead of neoarsphenamine once weekly there was again no significant drop in incidence, although the total amount of arsenic was very much reduced.

The above evidence suggested that although syphilis and the arsenicals can produce liver damage they cannot be responsible alone for the increase in jaundice observed in our clinic (M.I.H.). Ruge (1927) made the observation that in the German Navy the incidence of jaundice in syphilitics bore a definite relation to the incidence of infective (non-spirochaetal) jaundice in the general population. When the incidence rose in the non-syphilitics a parallel rise occurred in the syphilitics. Stokes, Ruedemann, and Lemon (1920) noted a similar phenomenon. The present rapid rise in the incidence of jaundice among syphilitics in this country has been observed over a period when infective hepatitis was becoming increasingly common in the general population. There would thus appear to be good reason for considering the third possibility of Goodman and Gilman's—namely, an infective factor.

#### The Role of Infection

The complete records of 119 male cases of early syphilis who had received all their antisyphilitic treatment at one clinic (M.I.H.) were available. The time interval between the attendance at the clinic when the first arsenical injection was given and the time of onset of jaundice was determined for each patient. A graph showing the number of cases of jaundice in each week following the first injection was prepared (see Fig.). The array ranged from the 11th to the 44th week after

Graph showing number of M.I.H. cases of post-arsphenamine jaundice occurring in each week of antisyphilitic treatment. (Total cases, 119.)

the first arsenical injection. The median lay in the 15th week. Of the 119 cases, 90 (76%) occurred during the 12th to 17th weeks (inclusive).

If it be assumed that some infective factor was transmitted from patient to patient, the latent or incubation period of most of the cases would appear to be between 12 and 17 weeks. The wide limits of the incubation period and the presence of 20 cases occurring after longer periods might be explained by assuming that infection did not take place until some injection later than the first. Some of the remaining 9 cases which occurred before the 12th week may not be late or post-arsphenamine jaundice, but may be examples of the early type discussed above.

It seemed unlikely that the disease was spread by contact, as is infective hepatitis, but that the spread occurred through inoculation of an infective agent when arsenical injections were being given. Bigger (1943) has pointed out that imperfect

sterilization might be responsible for leaving in the syringe infective material which could then be passed into the next person injected by the same syringe and needle. The incubation period in our cases of post-arsphenamine jaundice was probably between 80 and 100 days, which was about three times as long as that determined by Pickles (1939), Edward (1943), and Ford (1943) for infective hepatitis in non-syphilitic in which there was no possibility of transmission by inoculation.

The length of the incubation period and the possibility that an infective agent had been transmitted by inoculation suggests that post-arsphenamine jaundice might be identical with the jaundice which occurs after the administration of human blood products or of yellow fever vaccine containing human serum (Findlay *et al.*, 1937, 1938, 1939; MacNalty, 1938; Proper, 1938; Soper and Smith, 1938; Beeson, 1943; Memorandum by Medical Officers of the Ministry of Health, 1943; Morgan and Williamson, 1943; Steiner, 1944). Although the possible incubation periods recorded by these various observers are not identical the median for each series of observations falls within or slightly before the period in which the greater number of our cases of post-arsphenamine jaundice occurred (76% of cases between the 12th and 17th weeks). While this evidence is highly suggestive it is not sufficient to prove the complete identity of post-arsphenamine jaundice with the types following the use of human blood products. It does, however, appear to separate all these types of jaundice from the epidemic form of infective hepatitis such as described by Pickles.

An attempt has been made to obtain some precise information on the method of transmission of the disease. It was suggested by MacCallum early in 1943 that if transmission of the infective factor in post-arsphenamine jaundice was due to inoculation of infective material contained in imperfectly sterilized syringes, then if each patient were given a syringe at the beginning of his treatment and received injections only by that syringe after proper sterilization the transmission of infection ought to be eliminated. It was decided to treat 10 early syphilitic cases and to give each patient a new and unused syringe for his exclusive use for all his injections. (The syringes for this experiment were provided by Dr. MacCallum.) Such syringe and needles were washed and boiled both before and after each injection. Because of postings to units away from the Command only four of the ten were observed beyond 120 days after the first treatment. No case of jaundice appeared in this group in spite of the fact that the patients were in contact for about the first 14 days of treatment, and subsequently at least once each week, with men who later developed post-arsphenamine jaundice. One of the four men under observation proceeded on leave and received two arsenical injections at another clinic from syringes used to inject other patients. The syringes were not boiled after being used for previous patients, but had been rinsed with sterile water followed by 70% alcohol, and were given a further rinse in distilled water. This man developed jaundice later. The relevant data are given below:

Patient S			
Date of first injection	at "S" clinic	May 26, 1941	
" " second " "	" " "	Sept. 2	
" " first symptom of liver damage	" " "	Nov. 8	
" " icterus	" " "	Nov. 27	
Interval between first injection at "S" clinic and first symptom of jaundice	" " "	83 days	

This series, though short when taken in conjunction with Bigger's experiments, is strongly suggestive of blood transmission. The single case of jaundice after a probable accident infection might establish the latent or incubation period for post-arsphenamine jaundice as being about 12 weeks. It suggested, too, that patients transferred from V.D. clinics, where the incidence of jaundice was low, to M.I.H. clinic, where the incidence was high, might, if they developed jaundice, show some evidence that their infection took place at the latter clinic. Eight men were traced who had such histories. Details are given in Table I.

All these cases have time intervals between the first injection at M.I.H. clinic and the onset of jaundice which fall within the range of 12 to 15 weeks—precisely the range within which the greater number of cases of jaundice appeared in the large series of 119 patients. If it be assumed that the exact incubation period is 12 weeks from inoculation of the infective material (as occurred in the single case described above), then only

TABLE I

Case	Date 1st As Inj.	Date 1st As Inj. at M.I.H.	Date Appearance of Icterus	Days from 1st Inj. to Icterus	Days from 1st Inj. at M.I.H. to Icterus

	17/10/42	26/ 2/43	7/ 6/43	233	101

portion of the patients are infected at the first injection, but the chances of becoming infected are greater with each successive injection. This would explain the shift in the median to the 15th week in the long series, the large number of cases occurring up to the 17th week after the first injection, and the sporadic cases up to the 44th week.

### "X" and "Y" Diseases

The disease described by Pickles, Edwards, and Ford had an incubation period of about 28 to 30 days and was transmitted by contact with a person who was infective. In post-arsphenamine jaundice and in homologous-serum jaundice the incubation period is about three times as long and transmission is by inoculation of the infective material. These considerations suggested the possibility that there were two diseases—an "X" disease, i.e., infective hepatitis—and a "Y" disease, including post-arsphenamine jaundice and jaundice following the injection of human blood products as described above. Clinically and biochemically it has not been found possible to differentiate these diseases. When biopsy specimens from the liver are taken the pathological appearances have been shown to be common to each type of disease (Dible, McMichael, and Sherlock, 1943).

Assuming that two diseases do exist and that the infective factors are different, immunity conferred by one disease might not protect against the other. Pickles, in a private communication, is of the opinion that the immunity conferred by an attack of jaundice (infective hepatitis) is "as complete as that conferred by an attack of measles." His records contain only one instance of a possible reinfection. It would appear that there is but a remote chance of a reinfection with X disease. In our series of 105 cases of X disease no instance of a reinfection could be traced. There were no clinical relapses in this series. By analogy it might be expected that an attack of Y disease would confer similar immunity.

At one hospital (M.I.H.) 280 cases of jaundice were treated in the jaundice ward and one as an out-patient. All were syphilitics. Of this group seven developed a second attack of jaundice. The relevant data are given in Table II.

TABLE II

Case	1st Inj. As	1st Symptom of Jaundice	Interval between 1st Inj. and 1st Symptom (days)	2nd Attack of Jaundice began	Interval between Attacks (days)	Interval between Discharge from Hospital and Date of 2nd Attack (days)
H	9/12/41	26/ 1/42	48	29/ 6/42	154	137
M	9/ 7/42	9/11/42	123	1/ 3/43	112	98
B	14/ 8/42	22/ 2/43	192	29/ 7/43	157	119
L	29/10/42	8/ 3/43	130	5/ 5/43	58	50
C	12/12/42	21/ 3/43	99	22/ 5/43	62	33
E	13/ 5/43	10/10/43	150	3/11/43	24	7
Fs.	8/ 6/43	11/ 9/43	95	11/10/43	30	11

Patients E and Fs. were most probably examples of true relapse caused by untimely celebration of their discharge from hospital. There was no evidence that, either immediately before or during their stay in hospital, they had been in contact with a case of infective hepatitis or a person who subsequently developed the disease. Patients C and L had been seen at weekly intervals between their discharge from hospital and their second attack of jaundice. They were apparently quite fit during the interval and were on full duty. Arsenical injections had not been resumed. There was thus a possibility that their second attack was due to an infection with X disease after their discharge

from hospital. Contact with known cases could not be proved. Cases H and M could not have been reinfections with Y disease as they had received no injections of any kind at the hospital or elsewhere until four weeks before their second attack, when arsenical treatment was resumed. Toxic hepatitis due to the arsenical itself was ruled out as there was no supporting evidence to justify this possibility. There remained a possible infection with X disease, but again an attempt to trace contacts failed. Patient B's case was exactly similar to those of Patients H and M except that he resumed arsenical treatment only two weeks before the second attack. If the two patients who had a simple relapse be omitted there are left five possible examples of infection with X disease out of a total of 281 cases. This gives a possible "infection" rate at this hospital (M.I.H.) of 1.8%.

At another hospital, B, the patients under treatment in the jaundice ward included some who had X disease (infective hepatitis) and others with Y disease (post-arsphenamine jaundice). At no time did the ward contain only one of the two diseases. During a period of six months 80 cases of Y disease and 40 of X disease were treated. While there were no relapses or reinfections in any of the cases of X disease five so-called relapses occurred in Y-disease patients. An analysis of the time of appearance of the relapses showed that they fell within a period lying between the 30th day after admission to hospital and the 30th day after discharge. As it was possible in this group to be certain of full clinical and biochemical recovery, and as all had shown no abnormal response to test doses of neoarsphenamine, the presumption is that these cases were true infections with X disease and that such infections were contracted while in the ward. The "infection" rate was therefore 6.3% as compared with 1.8% in the other hospital (M.I.H.).

In Hospital B the cases of X disease occurred exclusively in U.S. Army personnel, while the Y cases occurred almost exclusively to British Army personnel. An analysis of the U.S. Army cases showed that all had received yellow fever inoculations at least eight months before they developed jaundice in England. Of the 40 cases 5 had developed jaundice within four months after their yellow fever inoculations and while still in the U.S. If it be assumed that post-vaccinal yellow fever jaundice is Y disease, then this disease did not confer immunity against an attack of X disease. That the second attack was X disease was proved by evidence of contact with cases of X disease 28 to 30 days before the second attack began.

The evidence so far is suggestive that an attack of Y disease does not immunize against X disease. It might be expected that an attack of X disease does not immunize against Y disease. Of the 360 cases of Y disease in both hospitals evidence of an attack of jaundice preceding the syphilitic infection was obtained in only 6 cases. The time interval between the attack of presumably X disease and the attack of Y disease varied between 10 years and 18 months. The evidence to support a diagnosis of X disease was not good, as it was impossible to secure a history of contact with other cases of jaundice, except in two of the six cases.

The recent large-scale epidemics of post-vaccinal yellow fever jaundice and of infective hepatitis ought to provide in the near future more convincing evidence than has been produced here on whether or not there are two diseases each of which provides no immunity against the other.

### Summary of Present Evidence

The evidence at present available may be summarized as follows:

X disease, or infective hepatitis, has an incubation period of about 28 to 30 days and is transmitted by contact. It can exist in a form in which icterus never appears but which is apparently sufficient to confer immunity against reinfection.

Y disease, whether late post-arsphenamine jaundice or homologous-serum jaundice, has an incubation period of 80 to 100 days and is transmitted by inoculation of infective material (blood, serum, or plasma).

An attack of Y disease presumably confers no immunity against X disease.

Evidence that an attack of X disease confers no immunity against Y disease is scanty and incomplete, but is suggestive.

Relapses of Y disease have been explained mostly on the grounds of an infection with X disease.

psychologies of the academic type and noticing how their authors ignore or merely hint at the existence of such stupendous and fundamental biological phenomena as those of hunger, sex, and fear, I should not disagree with, let us say, an imaginary critic recently arrived from Mars, who should express the opinion that many of these works read as if they had been composed by beings that had been born and bred in a belfry, castrated in early infancy, and fed continually for fifty years through a tube with a stream of liquid nutriment of constant chemical composition. To put it drastically, most of our traditional psychologists are about as useful for purposes of understanding the human mind as an equal number of dissertations on Greek statuary would be to a student eager for a knowledge of anatomy. Such a student at once learns that the object of his investigation, the human animal body, is very largely composed of parts offensive to the aesthetic sense, but this does not deter him from studying them as thoroughly as other parts. The typical psychologist, who might be expected to study his material in the same scientific spirit, does nothing of the kind, but confines his attention to the head and the upper extremities and drapes or ignores the other parts.

"Now I believe that the psycho-analysts are getting down to brass tacks. They have discovered that the psychologist's game, which seems to consist in sitting down together or with the philosophers and seeing who can hallucinate fastest or most subtly and clothe the results in the best English, is not helping us very much in solving the terribly insistent problems of life. They have had the courage to dig up the subconscious, the hotbed of all the egotism, greed, lust, pugnacity, cowardice, sloth, hate, and envy which every single one of us carries about as his inheritance from the animal world. These are all ethically and aesthetically very unpleasant phenomena, but they are just as real and fundamental as our entrails, blood, and reproductive organs. In this matter, I am glad to admit, the theologians, with their doctrine of total depravity, seem to me to be nearer the truth than the psychologists. I should say, however, that our depravity is only about 85 to 90%.

"In nothing is the courage of the psycho-analysts better seen than in their use of the biogenetic law. They certainly employ that great biological slogan of the nineteenth century with a fearlessness that makes the timid twentieth-century biologist gasp. But, making all due allowance for the extravagant statements of Freud and Jung and their disciples, any fair-minded student of human nature is compelled to admit that there is a very considerable residuum of accurate observation and inference in their accounts of the dream, of the perversions of the nutritive and sexual instincts, of the erotic conflicts and repressions, and of the surviving infantilisms. . . .

"To me one of the most striking indications that the psycho-analysts are on the right road is the fact that many of their theories have such a broad biological basis that they can be applied, *exceptis excipiendis*, to a group of animals so remote from man as the insects. This has not escaped Jung, who calls attention to the striking analogies between the nutritive caterpillar stage and human infancy, the chrysalis and the period of latency, and the imaginal butterfly and puberty in man. There are even cases of repression and sublimation as in the workers of social insects, and did time permit I could cite examples of multiple personality or of infantilisms—that is, larval traits which survive or reappear in the adults of many species. Insects undoubtedly sleep. Do they dream? If they do, what a pity that we shall never be able to apply the Freudian analysis to the dream of that symbol of sexual repression and sublimation, the worker ant!

"But these are trivial considerations. The great fact remains that the work of the psychiatrists is beginning to have its effect even on such hidebound institutions as ethics, religion, education, and jurisprudence, and that the knowledge that is being gained of the workings of our subconscious must eventually profoundly affect animal no less than human psychology, since the subconscious is the animal mind."

#### Psychology

Now let us turn to one other field close to that of psychiatry where differences from psychiatry may serve for the purpose of definition. As physiology is to the practice of medicine, psychology is—or should be—to the practice of psychiatry. In the history of medicine the investigation of the normal did not precede the study of the abnormal. The abnormal has revealed the normal as the exception illustrates the rule. Similarly, psychology as the study of the normal function of the organism has received much from psychiatry. Indeed, the whole method of experimentation in so far as it creates artificial conditions produces in some degree illuminating abnormalities. As a source of knowledge the abnormal precedes the normal.

There are psychiatrists who would be content to describe psychiatry as medical psychology, just as there are physicians who insist that medicine is physiology applied to disease. Though in theory psychology should play this role and thus

be the handmaiden to psychiatry, she is in reality a very green-haired girl with almost as much to unlearn as to acquire before she becomes indispensable to the psychiatrist. Patience rather than dismissal is indicated; for even now psychology, especially when well grounded in biology and physiology, is valuable. Already psychology gives real though limited service in mental testing, conditioned reflex research, localization studies, and in certain selective procedures like the Rorschach test.

#### A Summary

To summarize the foregoing: Human beings are not merely collections or assemblies of collaborating organs. They have functions and capacities characteristic of organisms as a whole and appropriate for individuals living in indispensable contact and collaboration with other human beings. What they do we call conduct or behaviour (and equally important, what they manage to keep from doing). Psychiatry is the field of study which concerns a very wide range of disorders, defects, or inadequacies of behaviour of these individuals. It has been wisely said that life's aim is an act, not a thought. In the same sense it is not merely mental phenomena that constitute the material of psychiatry, but that blend of instincts, emotions, thoughts, and feelings and physiological states which eventuates in conduct—in action or the inhibition of action. It is true that conduct will be affected by physical, chemical, or other disturbances in some part of the machinery of the body—e.g., bullet wounds, metabolic disorder, alcohol, bacterial disease. But it is also true that we witness disturbances for which we can find as yet no cause so simple and objective, where mood and motivation, emotions and instincts, and the faculties of adjustment to reality appear to be in conflict or disorder; and these derangements also are the task of the psychiatrist.

#### The Status of Psychiatry

Now for a few comments upon the status of psychiatry and I am done. Since 1880 medicine as a whole has profited immeasurably from two broad lines of study—bacteriology and cellular pathology. The one explained a host of diseases as due to invading micro-organisms, the other described in analytical terms of separate organs and organic disease the phenomena shown by sick people. There has been for the past fifty years, however, something approaching neglect of the patient as a person. Let me quote from a first-rate physician—Louis Hamman of Baltimore.

"To the specialist, psychiatry is another specialty operating in a contiguous but separate domain. To the internist, it is a vital and integral part of his work. Indeed, I find it impossible to formulate a clear expression of the relation of psychiatry to medicine, so intimately and inextricably are they bound together. The physician studies and practises psychiatry continuously, even when he protests that he has not the least knowledge of formal psychiatry. It is the chief instrument of his success, even though he may practise it unconsciously. . . .

"In spite of this growing importance it is the subject about which medical students know least and the one in which their training is most deficient. The reasons for this slighting treatment of psychiatry are many; I can mention only a few of the outstanding ones.

"1. The General Lack of Appreciation of the Importance of the Subject.—When I was a medical student psychoneurotics were objects of ridicule and contumely, not of serious study and sympathy. The patient with no gross lesion to justify his many complaints was neglected and avoided. The worst insult that could be cast at a fellow-student was to call him neurasthenic. After careful observation had established the fact that a patient had no organic disease professional relations were supposed to be at an end and he was dismissed with some reassuring remark as, 'There is nothing whatsoever wrong with you; your troubles are imaginary; go and forget them,' or even more curtly with a placebo and the ardent hope that he would never return. With the passage of years this brusque attitude has become somewhat softened, and yet essentially it is still the attitude of many physicians. The mind always seeks precise classification and is never more pleased than when experience can be snugly labelled. . . .

"In order to furnish tangible evidence of the important part psychiatric problems play in the practice of medicine I have reviewed the records of 500 consecutive patients who consulted me. To give the figures any value I must explain that my practice covers the whole field of internal medicine and that patients come to me or are sent to me chiefly for diagnosis. I have no reputation as a psychiatrist nor am I even suspected of having unusual interest or

talent in that field. Not one of the 500 patients consulted me on account of an overt psychiatric condition. . . .

"Among the 500 patients there were 116 (23%) without any discoverable organic cause for the symptoms of which they complained. In addition, there were 56 (11%) presenting minor organic lesions but with symptoms which could not possibly be explained by the lesions alone. In a word, one-third of the patients suffered solely or predominantly from functional disorders."

Strictly speaking, it might be stretching a point to say that all of these functional disturbances were due primarily to psychiatric disorders. Nevertheless, if you are willing to define the province of psychiatry as the broad field I have outlined, then surely the problems of these patients are of interest and concern to psychiatrists. For instance, a man otherwise well and competent suffers from very distressing digestive symptoms whenever he is worried, or for other reasons under nervous strain. Shall we consider this a psychiatric problem? I think we undoubtedly must, since here psychic influences play the chief role in disturbing the balance of the vegetative nervous system. What is commonly called the spastic colon invades the psychiatric field more prominently than it does the gastro-enterological.

With steady insistence psychiatrists have laid stress upon the whole personality of any and every patient—their own and those in every medical specialty. Psychiatrists, despite their isolation in asylums, despite inferior recruitment to their ranks and the taboo and horror associated with insanity, despite the time required for making their diagnoses, and despite their isolation from experimental methods and the fact that laboratory animals do not appear to develop psychiatric conditions (except Pavlov's experimental neurosis)—despite all these handicaps psychiatrists are nearer to adequate discharge of their duties than they have ever been before. For the first time man studies his own conduct dispassionately and in terms of cause and effect—not devils and disasters. Cannon's work upon the physiology of the emotions, the exceptional growth of neurophysiology, thanks to Sherrington and to new instruments of registering the changes of electrical potential in nerves, the stimulus of Freudian theory, of Pavlov's work on reflex behaviour, and the steady extension of scientific methods of study of psychiatric patients, are some of the factors in the progress of psychiatry.

Much remains to be done. Kolb of the United States Public Health Service reported that in 1939 \$200,000,000 was spent on mental diseases, yet not 1% of it for research. One child in every 20 in the United States will at some time of his life be in hospital for mental disease, and another child in the same 20 will at some time be psychiatrically disabled but not hospitalized. There are probably 6,000,000 feeble-minded persons of all grades in the United States, 80 to 95% at large in the population, 100,000 alcoholics and drug addicts, between 800,000 and a million mentally diseased, and 400,000 epileptics. There are more hospital beds devoted to psychiatric cases than to all other forms of disease. Ninety per cent. of the cost is at public expense. And in the face of the dislocation, loss, and sorrow in the families of the mentally disordered the statistician remains mute.

We are indebted to the Editor of the *Menninger Clinic Bulletin* for permission to republish this article.

Mr. Sydney Lamb was appointed secretary and organizer of the Liverpool Hospitals Council—now the Merseyside Hospitals Council (Inc.)—early in 1927, having already achieved notable success in Sheffield, where as secretary of the Hospitals Joint Council he increased the annual contributions from employees and employers by over £100,000 in five years. From this post of general secretary of the Merseyside Hospitals Council Mr. Lamb is about to retire. Starting in Liverpool with a rather small office, he worked indefatigably to make the "Id. in the E" principle an integral part of everyday life on Merseyside. To-day he controls a large organization which enables workers and employers to make their own contribution towards a complete hospital service—one of the most comprehensive in Britain. It assumes responsibility for the hospital service of a million Merseyside workers and their dependants, and has an annual income of £420,000. Among the many important posts held by Mr. Sydney Lamb was the office of general secretary and treasurer of the International Hospital Association, which took him to many of the great capitals and cities of both Europe and America. In 1941 he became honorary secretary of the British Hospitals Contributory Schemes Association.

## OCULAR SYNDROME IN ONCHOCERCIASIS

BY

J. GRAHAM SCOTT, M.D., D.O.M.S., B.Sc.

Major, R.A.M.C.

*Onchocerca volvulus* (the blinding filaria) is commonly found in certain parts of West Africa and America. It produces keratitis and iritis. Strong, Sandground, Bequaert, and Ochoa (1934) found microfilariae in affected eyes. Hisette (1932, 1938) described choroidoretinitis, retrobulbar neuritis, and optic atrophy in cases of onchocerciasis. Luna (1918, 1919) had previously described keratitis punctata onchocercosa due to filarial toxins.

It is proposed to describe cases in which (1) oedema of the upper lid, (2) proptosis, (3) ciliary flush, and (4) oedema of the optic nerve occurred as unilateral phenomena in two patients with onchocerciasis, and to suggest that a lymphatic block directly due to microfilariae or indirectly due to filarial toxins (as in Calabar swelling) is an explanation of the four symptoms.

### Case I

This case is that of a Gambian soldier, and is believed to be the first case of onchocerciasis described in a Gambian, it being uncommon among them. He was admitted to hospital on Dec. 31, 1942, complaining of a painful watering right eye. He had previously enjoyed good health and had experienced no trouble with his eyes until the day before admission. When admitted vision was 6/5 R., and 6/5 L. The right eye was watering and had a slight ciliary flush. The media were clear and the fundi normal. The case was diagnosed as early uveitis and treated with atropine 1% and hot-spooning 4-hourly. The next day the upper lid of the right eye was swollen and there was slight but definite proptosis.

Examination of the general and central nervous systems presented no abnormality on this or on any subsequent occasion, other than the eye signs to be described. The cerebrospinal fluid and white cells were normal. Radiographs of sella, sinuses, and orbits were normal. Blood films, day and night, revealed no microfilariae. A triple-centrifuged specimen of blood revealed a few *A. perstans*, a very common microfilariasis in West Africa. A snip of conjunctiva showed no microfilariae. The Kahn precipitation test was positive (+). (This is a common finding in a yaws-infected population.) Blood pressure was 100/70. The urine had no albumin or sugar.

In five days the proptosis became less, but the right fundus showed blurring of the disk. Next day vision was 6/36 R., 6/6 L. The lower half of the right disk was covered with exudate. The oedema of the upper lid and the proptosis gradually faded during the next 14 days, but the right fundus slowly developed a low-grade oedema, with swelling of the nerve head of 1 or 2 dioptres. The upper temporal veins became veiled with exudate, and a few flame-shaped haemorrhages developed round the disk at 10 and 7 o'clock. The macula remained within normal limits till the thirteenth day, when it slowly developed a complete star reflex. Fields were as follows. Right: depressed, with enlarged blind spot but no central or other scotomata; 1/1000 white gave 5 degrees field; 5/1000 gave 25 degrees field. Left: normal. Colour test (pseudochromatic): two mistakes right eye; normal left eye.

19th Day.—Temporal veins less veiled and oedema of nerve head subsiding. Vision: 6/24 R., 6/6 L.

33rd Day.—Right fundus returning to normal. Fan reflex at macula persists. Vision: 6/18 R., 6/6 L. Fields show no central scotoma for 1/1000 white or 5/1000 colour. Patient has been having 1% atropine and heat t.i.d. to the right eye and pot. iod. gr. 5 t.i.d. by mouth. After a provocative injection of 0.45 g. N.A.B. the Kahn reaction was "doubtful positive," and a course of 10 weekly injections of 0.60 g. N.A.B. was given.

60th Day.—Vision: 6/5 R., 6/5 L. The left fundus had been normal throughout, and the right fundus showed slight cuffing of vessels on leaving the disk and a faint fan-shaped reflex at the macula. The haemorrhages had been absorbed, and only a slight fullness of the upper lid remained. On the 75th day a slit-lamp became available. One microfilaria was seen in the right and left anterior chambers. There was no K.P., and the right cornea presented a few nebulae in the substance of the cornea. Blood films showed no microfilariae by day or by night.

90th Day.—One or two microfilariae have been seen in both eyes on most days since first noted. The course of N.A.B. is now finished. Vision: 6/5 R., 6/5 L. The right fundus is within normal limits. Patient discharged.

It was possible later to withdraw a microfilaria from the anterior chamber; this was found on staining to be *Onchocerca volvulus*. A skin snip showed many microfilariae (*O. volvulus*), although no nodules could be felt. The right eye showed one fresh yellow speckled opacity in the cornea, which I have seen only in cases of onchocerciasis.

The patient was seen again in 5 and 7 months. He was well and had no trouble with vision or with pain in the eyes despite the presence of microfilariae in each anterior chamber. The fundi were normal, except the faintest veiling of the margins of the right disk.

### Case II

The second case was admitted on July 3, 1943, with a painful swelling in the right axilla, mild oedema of the right upper eyelid, and ciliary flush. The axilla was incised and cleared in a normal fashion. The right eye, however, soon became closed with oedema of the upper lid, and proptosis developed. Both fundi remained normal, but vision dropped line by line over a period of 10 days from 6/9 on admission to 1/60. The right eye was painful with lachrimation. Radiographs of the orbits were normal. The Kahn reaction was negative. Central nervous and other systems were normal. The patient was unable to co-operate in perimetry. Day and night films showed scanty microfilariae (*A. perstans*), but a skin snip had many *O. volvulus*, and typical nodules were felt over the right and left iliac crests. No microfilariae were seen in either anterior chamber, but fine dots of pigment were observed on the posterior corneal surfaces.

On the 17th day vision was 6/12 R., 6/5 L.; oedema of the lid was lessening and proptosis and ciliary flush had cleared. On the 27th day vision was 6/5 R., 6/5 L. Slight fullness of the right upper lid remained. The right fundus was normal throughout, except for a transitory haziness on the 7th day, so the neuritis in this case was retrobulbar.

### Discussion

The syndrome presented by these two soldiers is not a familiar one in general ophthalmic practice. In the cases described the diagnosis must rest on probabilities, since no single finding was sufficient to establish the diagnosis beyond doubt. The presence of oedema of the upper lid, proptosis, ciliary flush, and optic neuritis indicates a lesion behind the eyeball. The probable causes are (a) haemorrhage, (b) tumour, (c) infection, (d) congestion.

(a) Haemorrhage can be excluded by the absence of subconjunctival ecchymosis.

(b) Tumour is improbable in view of the complete recovery, and lack of other signs pointing to neoplasm or cyst.

(c) Infection (i.e., an orbital cellulitis or a cavernous sinus thrombosis) is not supported by the findings. The absence of a history of previous sinus trouble, the healthy appearance of the orbit on x-ray examination, and the normal white cell count are against orbital cellulitis. The absence of a primary lesion on the face or in the mouth is against cavernous sinus thrombosis. A syphilitic optic neuritis is not commonly unilateral, and in the absence of choroidal changes and unequal pupils this diagnosis is improbable, especially in view of the negative Kahn in the second case. The group of demyelinating diseases has to be considered. Disseminated sclerosis is the commonest cause of a unilateral retrobulbar neuritis, but does not produce proptosis. Furthermore, this disease is very uncommon on the West Coast. Dr. H. Thomas has neither seen or heard of a case in 16 years' medical service on the coast, and Dr. Carmichael Wilson has seen only one case in Nigeria 18 years' service. Neuromyelitis optica and Schilder's disease are ruled out by the subsequent history of the cases.

(d) Congestion can be venous or lymphatic. Venous congestion is ruled out by the absence of early fullness of the retinal veins. The association of lymphatic swelling and filariasis is well recognized in elephantiasis, although the mechanism is not quite clear. The filariae in most cases are *Wuchereria bancrofti*, but Strong reports cases due to onchocerciasis. Calabar swelling, an anaphylactic oedema, is associated with *Loa loa*, so there is a precedent for suggesting that onchocerciasis can produce lymphatic swelling. A direct block of the retrobulbar lymphatics by a host of microfilariae is possible, but since microfilariae are well tolerated as a rule by the tissues this is not considered likely. More probable is the theory that an anaphylactic oedema can be produced in the orbit as a result of *O. volvulus* toxins, and that such an oedema is the explanation of the syndrome of oedema of the optic nerve and of the upper lid, with proptosis and ciliary flush.

### Summary

Two cases with proptosis, oedema of the lid, ciliary flush, and oedema of the optic nerve associated with onchocerciasis are described. One is believed to be the first case of onchocerciasis reported in a Gambian. It is suggested that the cause of the syndrome is an anaphylactic oedema caused by *Onchocerca volvulus*.

My thanks are due to Col. R. G. Gordon, officer commanding the 55th General Hospital, for his help and advice, and to Drs. Wilson and Thomas.

## THE NERVOUS COMPLICATIONS OF INFECTIVE HEPATITIS

BY

F. GRAHAM LESCHER, M.C., M.D., M.R.C.P.

Physician to the Derbyshire Royal Infirmary, and to the General Infirmary, Burton-on-Trent

The nervous complications which may arise during the course of infective hepatitis are by no means common. They occur occasionally in spirochaetosis icterohaemorrhagica, but they seem to be even rarer, judging from the literature, in the epidemic form of infective hepatitis.

### Nervous Complications of Weil's Disease

Apart from such conditions as mild headache, restlessness, delirium, convulsions, and coma, which are due more likely to the general infection than to any actual involvement of the nervous system, the nervous complication most often met with in Weil's disease is that of meningitis. Yet, judging from reports of cases in the literature, this is of comparatively infrequent occurrence, despite the writings of some French physicians. Meningitis occurred, for instance, in only 3 of the 40 cases of this disease reported by Davidson and Smith (1936).

Meningitis may occur in Weil's disease with or following the jaundice. It may even be the prominent feature in this infection, the jaundice and haemorrhages being slight or even absent—"spirochètose méningée anictérique" of Costa and Troisier (1916, 1917). The cerebrospinal fluid is under pressure, and it may be clear or opalescent, with a fibrinous clot which forms on standing. There is a pleocytosis, with a predominance of the polymorphonuclear variety in the graver cases, lymphocytes in the less severe. Spirochaetes may be found in the fluid, and if the latter is injected into suitable animals jaundice and haemorrhages will generally occur. Eleven cases of meningitis of leptospiral origin, proved by the inoculation into guinea-pigs of the patient's blood or cerebrospinal fluid, have been reported by Costa and Troisier. Cochez and Fichet (1933) have published an account of three similar cases with, however, no obvious signs of jaundice. Inoculation of the urine, blood, and cerebrospinal fluid into guinea-pigs caused jaundice and haemorrhagic lesions in the liver and lungs, and spirochaetes were found in the livers. Agglutination reactions against *L. icterohaemorrhagiae* were positive in the sera of all three patients. These authors emphasize the following additional clinical signs as particularly characteristic of this disease: mild meningeal signs, labial or palpebral herpes, and conjunctival infection. Troisier and Boquien (1933) have examined a number of case histories of patients suffering from meningitis of leptospiral origin, accompanied with, or without, jaundice. Schöffner and Walch-Sorgdrager (1940) had, up to 1936, collected 25 case reports of meningitis from among 312 Dutch patients suffering from Weil's disease. According to their experience, meningitis is commoner in this infection without jaundice; so it seems advisable that serological tests should be carried out in all cases of non-pyogenic meningitis in which the aetiology is obscure. According to the reports of most

authors, nervous symptoms tend to appear during the acute phase of the disease, although Davidson and Smith (1936) and Jurgatroyd (1937) have each reported a case of Weil's disease in which meningitis occurred at least four months after the jaundice.

Recently I have seen a patient with Weil's disease in whom the illness started with violent headache and vomiting. Two days later jaundice appeared. On admission to hospital there was slight stiffness in the muscles of the neck. The cerebrospinal fluid was under increased pressure and was pale yellow in colour. It contained 5% neutrophils and 25% lymphocytes, and 80 mg. of protein per 100 c.c.m. The gold curve was normal. No spirochaetes were found in the fluid. There was marked hepatic and renal impairment. Nevertheless this patient made a good recovery, both clinically and biochemically.

Whereas in Weil's disease meningitis may not be quite so uncommon as is generally supposed, yet the involvement of the nervous parenchyma itself is decidedly rare. Mortensen (1940) was able to find only four cases in the literature in addition to one of his own. Two of these patients suffered from peripheral neuritis in the lower limbs, the others with myelitis. His own case was one of jaundice which at first was thought to be due to Weil's disease; but the serological reactions were abnormal, so that it was more likely to be due to an infection with a leptospira of a different type. Three weeks after the beginning of the illness signs of meningitis appeared, together with a transitory flaccid paralysis of the lower extremities. The patient made a good recovery. The same author has found in the literature the reports of a few cases of Weil's disease with paralysis of the third, sixth, and seventh cranial nerves.

### Nervous Complications in Epidemic Hepatitis

Nervous complications seem to be uncommon in epidemic hepatitis, although perhaps if a special watch were kept their occurrence might be found to be more frequent than the literature would suggest. As in leptospiral infections, the least uncommon of these nervous complications is meningitis.

Fliessinger (1924) has reported the case of a young man who developed meningitis. Less than a week after the onset jaundice appeared. He was thought to be suffering from Weil's disease, but spirochaetes were never found in the blood, nor in the urine or cerebrospinal fluid; and although inoculation of some of the patient's blood into a guinea-pig caused the death of the animal, jaundice did not occur, nor were haemorrhages or spirochaetes found in the internal organs. The patient's serum did not agglutinate leptospirae. Among the 300 cases of epidemic hepatitis of which an account was published by Ford (1943) there was only one that showed signs of meningitis. Waring (1943) has reported a case of his type of hepatitis in which meningitis started five days after the onset of jaundice. The cerebrospinal fluid was opalescent and under increased pressure. There were 544 cells per c.m.m., chiefly lymphocytes, together with an increased amount of globulin. This patient made a good recovery.

Lemierre, Lhermitte, and Bernard (1929) have related an interesting case of a young man who complained of acute abdominal pain and vomiting for which no cause was found on laparotomy. Shortly afterwards acute painful flaccid paralysis developed in the lower limbs, to be followed in a short time by a similar condition in the upper limbs. The right trigeminal and facial nerves then became affected, together with loosening and falling out of the teeth. Meanwhile, jaundice developed, which progressed until death occurred from asphyxiation due to paralysis of the muscles of respiration. At necropsy areas of degeneration were found in the trigeminal, vagal, and hypoglossal nuclei; also in the anterior horn cells of the spinal cord. But although the liver was enlarged, no appreciable changes were found. Lemierre has reported a case of a patient who developed spastic paraplegia during an attack of epidemic jaundice.

Lelong and Bernard (1935) have had under their care during a local epidemic a girl of 14 suffering from infective jaundice. Four weeks after the beginning of her illness polyneuritis developed in the upper and lower limbs, starting distally and spreading upwards. Serological tests to leptospirae were negative; nor was the organism found in any of the body fluids. Complete recovery eventually took place. Newman (1942), describing an outbreak of infective hepatitis, noted the occurrence of mild meningitis and neuritic signs in some patients; while Brain (1943) has reported the occurrence of convulsions, hemiplegia, and mild polynuritic signs which preceded the onset of epidemic jaundice. Out of 170 patients suffering from epidemic infective hepatitis studied by Cameron (1943) in Palestine, only five showed nervous complications. Two developed mental disturbance, which was attributed to hepatic insufficiency. In the other three patients temporary ocular difficulty with accommodation occurred. All made a good recovery. No case of meningitis was seen by that author.

Judging from the various accounts of cases published in the literature and from one's own experience, the prognosis of nervous complications in infective hepatitis seems to be good.

### Two Cases of Epidemic Hepatitis with Parenchymatous Disease of the Nervous System

**Case 1.**—A housewife aged 28 was admitted to the Derbyshire Royal Infirmary on Jan. 28, 1943, complaining of weakness of the arms and legs, together with jaundice. At the time there was an epidemic of jaundice in the town. She had not come into contact with chemicals nor did she use hair-dye or cosmetics. She was accustomed to an ordinary mixed diet and showed no signs of dietetic insufficiency. On the night of Jan. 7 she went to bed with a cold and headache. The next day she complained of numbness and weakness in the fingers, then in the hands and forearms, and shortly afterwards in the feet and legs. A week later jaundice was noticed. The urine was dark in colour; there was no diarrhoea, and no alteration of colour in the stools.

On examination she was a well-nourished woman; cerebraation was good, there was no anaemia, and jaundice was pronounced, being more so on the face, chest, and abdomen than on the lower limbs. The lower edge of the liver was felt three fingerbreadths below the costal margin. The spleen and lymphatic glands were not enlarged. There was a marked symmetrical weakness and wasting of the muscles of the hands, forearms, and to a lesser extent of the arms and shoulder-girdles, together with loss of reflexes. A similar condition, though less pronounced, was present in the lower limbs. A slight degree of objective sensory loss was found over the hands and feet. The functions of the bladder and rectum remained unaffected. Nothing abnormal was found in the other systems. On most evenings for the first three weeks after admission her temperature was raised to between 99 and 101° F. The urine contained bile pigment but no bile salts. About the seventh week a small amount of albumin was present for a short time. The cerebrospinal fluid was examined two days after admission. It was yellow in colour, but showed nothing else abnormal. The blood contained 4 mg. of bilirubin per 100 c.c.m. The serum gave negative agglutination tests to *L. icterohaemorrhagiae*. The leucocyte count was never over 9,000 per c.m.m. The jaundice cleared up within about six weeks of admission, and a month later the polyneuritis had improved sufficiently for her to leave hospital, and to attend for treatment as an out-patient. Subsequently she made a complete recovery.

**Case 2.**—An R.A.S.C. driver aged 24 was admitted to hospital in Persia during Feb., 1943, suffering from epidemic hepatitis. He was told me that this condition was common in that country. He was discharged to duty eight weeks later. On April 28 he suddenly felt giddy and sick and complained of headache. On readmission to hospital the next day he was feverish and drowsy. A few days later, on waking up, he was unable to move his left upper limb, and his left leg was weak. On examination he was found to have a left hemiplegia of the upper neurone type, together with a left homonymous hemianopia. Nothing abnormal was observed on examination of the rest of his nervous system, nor in his cardiovascular or any other system, with the exception that his blood pressure was only 100/55. Two weeks later the cerebrospinal fluid pressure was normal, although the pressure was not given. The Wassermann reaction in the blood and cerebrospinal fluid was negative. The white cell count in the former was 10,500 per c.m.m. Nothing abnormal was ever discovered in the urine. He was invalided home and admitted to the Derbyshire Royal Infirmary last September. He still showed signs of a left hemiplegia with left homonymous hemianopia, although both are now improving.

### Discussion

From the paucity of the sporadic reports of nervous complications occurring during infective hepatitis, it can be argued that there may be a possibility of coincidence and that two separate diseases may coexist. On the whole, however, the probability is that the hepatitis and the complications in the nervous system are but two phases of the same disease. It is, of course, well known that certain pathogenic viruses, such as that of poliomyelitis, have a selective action on the nervous tissue. Other viruses, such as those causing measles, chicken-pox, mumps, atypical pneumonia, etc., may under certain circumstances infect the nervous system. Now, although definite proof that epidemic hepatitis is caused by a virus infection is still lacking, yet during the last few years evidence that it is so caused has been accumulating. Thus, if this assumption be correct, it is not unreasonable to suppose, or even to expect, that nervous complications could occur in some of those who suffer from epidemic jaundice. Another possibility is that lowered resistance of the liver in infective hepatitis may predispose to infection by the same or a different virus in other parts of the body. During the past

year, for instance, I have seen herpes develop in several patients who were suffering from infective hepatitis.

Judging by the analogy of the affinity of the *Spirochaeta pallida* for nervous tissue even in the early stage of syphilis, it is not unreasonable to assume that the nervous system may also be affected by other spirochaetes, such as *L. icterohaemorrhagiae*, during the course of its invasion.

If the association of nervous complications with infective hepatitis is kept in mind, it may be found that this combination, especially in cases in which the jaundice is not obvious, is not so uncommon as is at present supposed. Therefore, all cases of so-called "aseptic meningitis" of doubtful aetiology, or polyneuritis without obvious cause, should be carefully scrutinized for the presence of latent jaundice. The association of jaundice with nervous complications may possibly be further exemplified by such a condition as progressive lenticular degeneration (Wilson's disease), in which cirrhosis of the liver and a varying degree of jaundice occur together with involvement of certain parts of the brain, especially the corpus striatum.

### Summary and Conclusions

The occurrence of nervous complications in Weil's disease and in epidemic hepatitis has been discussed.

Meningitis is the nervous complication most commonly met with in both diseases.

Disease of the nervous parenchyma, though it does occur, is rare in both infections.

Meningitis occurring in a patient suffering from Weil's disease has been described; also two cases of epidemic hepatitis, in one of which polyneuritis developed. In the other, hemiplegia, presumably due to an encephalitis, occurred within a few weeks of the attack of epidemic hepatitis.

While the possibility of coincidence has been kept in mind, the probability is that the hepatitis and the nervous complications are but two phases of the same disease.

This combination may be found to be not quite so uncommon as was formerly supposed, especially if the presence of latent jaundice is looked for in all cases of infective nervous disease of doubtful aetiology.

## SURGICAL PROBLEMS IN FORWARD AREAS

BY

GUY BLACKBURN, M.Chir., F.R.C.S.

Major, R.A.M.C.; Surgeon to a Field Surgical Unit

The scope of surgery in forward areas has advanced in recent years to more than life-saving measures and heroic ablations, often in vain. In their place there is, it is true, major surgery with a high proportion of amputations; but resuscitation, chemotherapy, and new views on after-treatment have altered the principles and results out of all recognition. Difficulties, of course, remain that experience alone can solve, and when not to operate and when not to evacuate are among the most striking. Evacuation, indeed, controls the whole problem; and familiarity with the mode of transport and distances involved should be an essential part of a forward surgeon's information. Many a successful technical procedure has been ruined by premature evacuation, many a wounded man set back further by a long ambulance ride than improved by the resuscitation not long preceding it. Cases of burns and thoracic and abdominal injuries illustrate this point well.

The surgeon in forward areas has admittedly the easiest task in one respect, for the field is new ground, surgically

speaking, and the line of approach determined by the wound agent. The position of the wounded man at the time of injury and the type of missile may, however, modify this appreciably. Buttock wounds, in particular, demonstrate this fact, no more than 10 to 15% involving the peritoneal cavity. With regard to the type of missile, coincident blast is a complicating factor, too easily forgotten, as that of the lower lobes of the lung in wounds of the upper abdomen. Gross external with less internal damage by mortar wounds is less likely to mislead than the converse with shell or rifle wounds. In all types, however, the through-and-through wound may well be the problem. This, *par excellence*, is the wound to be left alone, especially when of the "gutter" type in subcutaneous tissues. Wounds of the right upper quadrant of the abdomen, involving the liver only, may also fall into the same category.

### The Abdomen

Abdominal wounds, in general, are still prognostically the worst, an all-in mortality of 50% being my experience. That of numerous surgical colleagues in the North African campaign: This is high, perhaps too high; but many of the factors determining it are beyond the surgeon's control. The interval between receipt of injury and operation is still the most important, and it is reasonable to suggest that every hour after six is more serious than two before it. Civilian figures for mortality of operations for perforated peptic ulcer provide a close parallel. (In the abdominal injuries dealt with by me in forward areas 10 to 12 hours was the average time between wounding and operation.)

Once the patient reaches the operating centre, however, many problems arise—perhaps more in the five or six days after operation than at the operation itself. Given blood instead of plasma, which is no substitute in cases with mesenteric bleeding, the decision and moment to operate are not, as a rule, difficult to determine. The approach then is in the line of the entry wound, and a buttock wound, for example, should be explored first before proceeding to deal with the intraperitoneal damage complicating it. At times, as a result, laparotomy will be found unnecessary; for abdominal rigidity with these, as with thoracic wounds, may easily be found misleading.

The importance of searching the alimentary canal from stomach to rectum has been stressed by numerous observers, and a patient too ill to stand this is too ill for operation. The exceptions are few enough to ignore. With this proviso, the plan should then be clear, and the task usually involved is exteriorization of the large gut and suture or resection of the small. The higher the lesion, of course, the better the prognosis. Even then, however, coincident injuries to other parts of the body may turn the scale, as it has been the exception rather than the rule to have to deal with a single wound. Too often, in fact, the wounded man provides an operation list in himself.

This raises the interesting subject of abdomino-thoracic wounds, which account for 20% of all wounds of the abdomen. These are more serious on the left than on the right side, but experience has shown that they are not necessarily grave than simple wounds of the abdomen. The abdominal injury in these cases is likely to be high and the bowel may be intact, the liver or spleen being the only viscus damaged. Simultaneous renal injury may occur—one notable case in the series under discussion necessitating nephrectomy, splenectomy, and closure of a large pleural defect, without untoward result. A successful cholecystectomy and duodenal repair has also been done for a right-sided abdomino-thoracic injury.

Post-operative continuous gastric suction and measures designed to prevent ileus repay all the care they demand; but a proportion of disappointing results remain which, at times, seem hard to explain. Why, for example, should pulmonary oedema have proved fatal in gunshot wounds of the spleen where no more than three pints of blood or plasma had been given in the 24 hours after operation? Why too, unless hypovitaminosis is the explanation in an army in the field, should a plastic peritonitis be the cause of death three weeks or more after operation? A typical example occurred in a man requiring resection of four feet of ileum and a colostomy for visceral injuries from a machine-gun, seen within five hours

Evacuation to a general hospital was delayed for more than fortnight, and the patient died nearly three weeks after this. The holding of patients for at least ten days after laparotomy made a vast difference to results, and by this time the issue was usually clear. Even then, however, evacuation by air or slow stages is the method of choice.

#### Chest Wounds

These are not, as a rule, difficult to deal with in forward areas, the minimum possible being done after closure of open wounds of the pleura. In a series of more than 60 cases only one required operation for bleeding from an intercostal vessel reducing a haemothorax. Repeated aspiration in this instance aided to prevent displacement of the apex beat to the fifth right interspace three inches from the midline. Surgical emphysema likewise has necessitated intervention only once in the same series.

#### Limb Injuries

Sixty to eighty per cent. of all wounds involve the limbs, and the lower more often than the upper. Immobilization of a standard type simplifies the problem in these cases. Illustrative and valuable examples are the Tobruk plaster for fractures of the femur and thoraco-brachial plaster for the humerus. Plaster cuffs for amputation stumps have also proved useful. Coincident injuries, such as a Pott's fracture with a fractured femur, can complicate the picture appreciably.

Of all fractures perhaps those of the upper third of the femur must be regarded as the most dangerous, associated in dispatch riders, who are the commonest victims, with head injuries which may also be grave. The value of radiographs in these as in all fractures in forward areas has too often been exaggerated, as immobilization and not realignment is the surgeon's task. Excision of the wound is of course required, and difficulty is often experienced in distinguishing bone fragments from foreign bodies. The errors, however, can easily be rectified when definitive treatment is carried out after evacuation.

Amputations, as already stated, are numerous, and primary suture is no more admissible here than in any other site. Blood transfusion in these cases is usually vital, and for double amputations imperative. One such case did well although operated on 15 hours after injury with massive destruction of one leg below the knee and gas gangrene in the other.

Gas gangrene has been encountered more than a dozen times in 500 cases, and the interval since wounding has twice been less than eight hours. One case oddly enough presented coincident maggot infestation, and the wound was (as usual in these cases) very clean. Excision of the affected muscle group proved effective. The diagnosis in the majority of cases, however, is made not from an inspection of the wound but from the patient's general appearance—the sallow, vivid look, incipient delirium, and restlessness being characteristic features. The presence of gas in the wound is unusual and has been noted only once. Anaerobic gangrene, in fact, might be a more descriptive and apposite term. It may even be fair to say that the presence of gas in gas gangrene, so-called, is as useful in establishing the diagnosis as skeletal secondaries in carcinoma of the breast.

Chemotherapy in these infections is an adjunct to and not a substitute for radical surgery. Buttock, thigh (lateral aspect), and calf wounds, for anatomical reasons, are those most apt to develop gas gangrene, and prophylactic serum for all of them may well have reduced the incidence of this complication. There again postponement of evacuation for some while after operation is of the greatest value. In these cases, as in large wounds with gross sepsis, secondary haemorrhage is the real danger of the convalescent period. When it occurs nothing but ligation of the main vessel involved is likely to be effective.

#### Burns

Routine treatment with sulphanilamide and petroleum jelly gauze after gentle but thorough cleansing with saline is still the method of choice, and it is the anaesthetist rather than the surgeon whose task is difficult. General agreement will probably be expressed with the danger of peptothal in extensive burns as in head injuries. Intravenous morphine has, in fact, proved much more satisfactory, and can be used with advantage for subsequent dressings at five-day intervals.

#### Conclusions

Evacuation controls the problems of surgery in forward areas. The number rather than the nature of wounds may be the most important prognostic feature.

The all-in mortality of abdominal wounds is 50% or thereabouts.

Abdomino-thoracic wounds are not necessarily more serious than abdominal.

No patient should be evacuated until ten days after a laparotomy.

Radiographs of fractures in forward areas are unnecessary in nearly all cases.

"Anaerobic gangrene" is suggested as an alternative to "gas gangrene." The presence of gas is a late manifestation.

Intravenous morphine is the anaesthetic of choice in the treatment of burns.

## Medical Memoranda

### Severe Granulocytopenia from Sulphaguanidine

A recent M.R.C. Memorandum (1943a) reports that sulphaguanidine has shown little toxicity to date, although nausea, drug-rash, and fever have occasionally been noted. The occurrence of severe granulocytopenia in a young adolescent treated for Sonne dysentery with moderate doses of this drug is therefore of some importance.

#### CASE RECORD

A girl aged 15 who had complained of headache, vomiting, and diarrhoea since the previous day was admitted to an E.M.S. hospital with a pyrexia of 101.2° and tenderness over the course of the colon. Her general condition was good and the frequent watery stools contained no blood or noticeable excess of mucus. Desoxy-epitope cultures produced a heavy growth of *B. dysenteriae* Sonne.

Sulphaguanidine was begun on the third day of the illness, 1.5 g. being given three times daily in the first three days. By this time the temperature had become normal and the stool cultures negative, and the dose was reduced to 1 g. three times daily, which was continued for four days. Thus a total of 25.5 g. of sulphaguanidine was given in seven days.

Six days after the drug had been discontinued the stools became relaxed and the cultures again became positive. A second course of sulphaguanidine was begun eight days after the conclusion of the first, 1.5 g. being given four times daily. After only two doses the temperature, previously normal, rose to 100.2° and there was complaint of a feeling of lassitude and slight headache. The temperature showed morning remissions to normal, but the malaise persisted, and on the third day, when a total of 15 g. had been given, the second course of sulphaguanidine was stopped. On this day the total leucocyte count was 5,500 per c.mm., of which 64% were polymorphs. The following day the temperature showed no morning remission and the leucocytes had fallen to 4,100 per c.mm., of which 38% were polymorphs. A day later the pyrexia reached 103.2° and the leucocyte count was 2,000 per c.mm., of which only 10% were granulocytes.

Sodium pentnucleotide was given in 10-cm. doses three times daily for four days, and twenty-four hours after starting it the leucocyte count had improved to 4,000 per c.mm. Of these 38% were of the granulocyte series, 4% being myeloblasts, 16% myelocytes, and 18% polymorphs. Thereafter there was gradual improvement, but six days elapsed before primitive white cells ceased to be present in fair numbers and before the temperature became normal. The red cells were not affected. There were no necrotic lesions and no petechiae.

#### COMMENT

Sulphaguanidine is used in the treatment of bacillary dysentery because of the local bacteriostatic action of the proportion of the total dose given which reaches the colon unabsorbed and is finally excreted in the faeces. Attention has centred on this action, and it requires to be emphasized that approximately two-thirds of the amount administered by mouth is absorbed before the ileo-caecal valve is reached (M.R.C. Memo., 1943b). That relatively low blood concentrations occur with this sulphonamide is due in far greater measure to rapid elimination in the urine than to poor absorption from the intestine (Fior and Poth, 1941). The possibility of agranulocytosis resulting from the administration of sulphaguanidine therefore merits attention, especially as the drug is often given to large groups of cases in epidemics, when regular checking of the granulocyte count may be impracticable.

That agranulocytosis is liable to occur during second courses of treatment has frequently been observed with other sulphonamides. In the above case the early onset of headache, lassitude, and slight pyrexia after the resumption of sulphaguanidine is suggestive of sensitization by the first course of the drug.

I wish to thank Dr. W. A. Bullough, County Medical Officer of Health, for permission to publish this report.

### Megalocytic Anaemia in a Young Vegetarian

Trowell (*Lancet*, 1943, 1, 43) of the Uganda Medical School reviewed the subject and literature of deficiency anaemias of malnutrition, with special reference to macrocytic anaemia. The present case is of interest in showing, although far from fully investigated, certain unusual features in a type of anaemia apparently uncommon in this country.

#### CLINICAL HISTORY

On Aug. 5, 1941, a lorry-driver, a single man aged 20, was referred to the department by Dr. J. Strachan of Leyland, for a blood count. In April, 1941, three of his teeth had been extracted because of soreness of the tongue and mouth. In May, tiredness, breathlessness, and loss of colour were first noticed; and these, the only symptoms, steadily increased. For 15 years he had been practically a vegetarian. For breakfast he had bread-and-butter with either salad of lettuce and tomato, or jam; treacle, or marmalade; and for lunch bread-and-butter, potatoes in gravy with peas or carrots, rice pudding; meat was taken at most as scraps in a weekly olla podrida. His tea was similar to the breakfast, with home-made cakes, biscuits, or fruit pies; and his supper consisted of bread-and-butter. The patient had never been fond of cheese, bacon, meat, eggs, or liver, and only took milk in tea, coffee, or cocoa at each meal. His parents, sister, and two brothers were all well and were not vegetarians; there was no family history of anaemia.

**Examination.**—Well-built and well nourished; marked pallor of mucosae; tachycardia; spleen impalpable, reflexes normal; tongue slightly smooth at the edges; onychia not marked. Blood: Hb, 35% (Haldane); red cells, 1,400,000 per c.mm.; C.I., 1.25; reticulocytes, 1.5%; mean diameter of red cells, 8.2  $\mu$  (diffraction method); mean corpuscular volume, 114 cu.  $\mu$ . White cells, 10,600 per c.mm.; differential count, normal. Red cells showed variability of size, shape, and staining; but no nucleated or stippled forms were seen. Plasma bilirubin, 0.85 mg. per 100 c.cm.; urea, 35 mg. per 100 c.cm.; W.R., negative. The urine showed no excess of urobilin.

The uncommon diet was viewed with suspicion, but the patient was unwilling to come into hospital, and was treated in bed at home as a case of presumptive pernicious anaemia. Between Aug. 6 and 29 he received injections of anahaemin in doses of 6 c.cm., 4 c.cm., and 8 of 2 c.cm. (total, 26 c.cm.).

**Progress.**—On Sept. 2, 1941, a gruel test meal revealed histamine-fast achlorhydria. The blood count showed: Hb, 85%; red cells, 4,400,000; C.I., 0.9; mean cell diameter, 7.5  $\mu$ . From that date until July 4, 1942, the patient received an injection of 2 c.cm. of anahaemin fortnightly. Counts done in Dec., 1941, and in Feb., April, and June, 1942, showed haemoglobin never less than 95% and not fewer than 5,000,000 red cells per c.mm., with a mean diameter of not more than 6.9  $\mu$ . Since Aug., 1941, a normal amount of meat, bacon, and milk had been taken in the diet. In July, 1942, it was decided to stop the injections and watch for a relapse. On five occasions between Aug. 4, 1942, and Jan. 18, 1943, haemoglobin was not less than 100%, nor the red cells below 5 millions. On Jan. 22, 1943, a test meal of 50 c.cm. of 7% alcohol showed a spontaneous secretion of free hydrochloric acid (from 8 to 12 c.cm. N/10 NaOH per 100 c.cm. of juice in the first three samples, rising after subcutaneous injection of 1 mg. of histamine to from 50 to 60 c.cm.), and the diagnosis of pernicious anaemia was abandoned. Fragility of the red cells was found to be normal at this time. Regret that marrow films were not examined before and after starting liver treatment, and a more delicate therapeutic experiment planned, is tempered by the patient's pleasure at his quick return to full fitness, and the prospect of relief from lifelong treatment. On Nov. 2 the patient felt and looked very well. His haemoglobin and red cell diameter were normal; and his reticulocytes numbered less than 1%.

#### COMMENTS

Points of note are: (1) The patient's good state of nourishment, indicative of the selective "anaemia-producing" action of his defective diet. (2) The early histamine-fast achlorhydria, but with a normal test meal 5 months later: Trowell found free HCl "almost always present." (3) The rapid improvement of the anaemia following anahaemin in moderately large though not massive dosage.

I wish to thank Drs. Strachan and F. B. Smith for their co-operation and for permission to publish.

R. T. COOKE, M.D.Ed.

Assistant Pathologist,  
Preston Royal Infirmary.

## Reviews

### DISEASES OF THE BONES

*Medical Clinics on Bone Diseases. A Text and Atlas.* By I. Snapper, M.D. (Pp. 225; illustrated. £3 7s. 6d.) London: H. K. Lewis and Co 1943.

Twenty years ago editors of Systems of Medicine were apologetic in approaching a contributor to write the section on diseases of the bones, for they seemed such a disconnected collection of conditions. Now the position has changed completely. Recklinghausen's disease has been proved to be of endocrine origin, and this has reacted on our interpretation of bone lesions in long-standing renal insufficiency. Osteomalacia and rickets have vindicated their status as deficiency diseases. The relationship of leukaemia, multiple myelomata, and hyperthyroidism to the skeleton has proved to be closer than was supposed. Lipoid granulomatosis affecting the bones has been recognized as the cause of new syndromes. X rays and biochemistry have greatly helped in formulating these new points of view, as to a lesser extent has the technique of sternal puncture. All this has put the earlier observations of Paget, Bence-Jones, Davies-Colley, and von Recklinghausen into their proper perspective as part of a growing synthesis. To that synthesis the present volume makes a sympathetic contribution, with admirable clinical descriptions and discussions, a bibliography, and striking illustrations.

We have come to realize that, whereas a parathyroid adenoma may be the cause of a profound disturbance of skeletal structure, it is also true that hyperplasia of the parathyroids may be a secondary and compensatory effect, as maintained by Erdheim, in various diseases. Thus, in osteomalacia they enlarge to deal with the excess of calcium and phosphorus set free by the destruction of bone, while chronic renal failure, if accompanied by acidosis, as it often is, stimulates enlargement of these glands. This interrelationship between the kidney and the parathyroids is further exemplified by the renal calculi composed of calcium salt which so often form in hyperparathyroidism. Indeed, latent hyperparathyroidism has been held to be responsible for between 0.5 and 2% of all renal calculi. The enlargement which may follow a complete biliary fistula is presumably to compensate for the consequent ill-absorption of the fat-soluble vitamin D. Fortunately the tendency to remove the parathyroids for the relief of osteo-arthritis or otosclerosis has passed.

Full justice is done to the pioneer work of J. P. Maxwells in China on the essential unity of osteomalacia and ante-natal and post-natal rickets. The way in which the social custom of that country lead to severe foetal and benign infantile rickets and to the prevalence of osteomalacia—a rare disease in Europe—is discussed in an interesting manner. Complicated syndromes may also arise by the superposition of avitaminosis on pre-existing bony disease. It has been recognized that in Paget's disease there is a notable increase in phosphatase although the metabolism of calcium and phosphorus is normal and the explanation seems to be that this augmentation occurs under any condition in which there is hyperfunction of osteoblasts. It is indeed a non-specific sign. The treatment of Paget's disease by carefully controlled injections of parathormone, followed by ultra-violet rays, seems to hold prospects in a hitherto incurable disease. Leontiasis ossea regarded as a syndrome of the same order.

Lipoid granuloma may form islands of foam cells laden with cholesterol esters in fibrous tissue, but when it attacks bone it has a predilection for the skull and pituitary for which the syndrome of Hand-Schüller-Christian disease resurges. In Gaucher's disease a special lipoid—kerasin—is abundant in the bone marrow, so that sternal puncture has become an important diagnostic technique in its recognition. The concluding chapter on multiple myeloma indicates that some connexion exists between it and myeloid leukaemia, and that

paration which has been made between different diseases the blood-forming organs has been too rigid.

The whole work is a fascinating and important study, which would be difficult to praise too highly, for it is a model of its kind which reflects great credit on all concerned in the production.

## AN ENCYCLOPAEDIA OF HISTOLOGICAL METHODS

*Microscopic Technique in Biology and Medicine.* By E. V. Cowdry, Professor of Anatomy, Washington University, St. Louis. (Pp. 206. 54.00 or 22s.) Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1943.

His new work by E. V. Cowdry is entitled *Microscopic technique in Biology and Medicine*. Except in so far as it deals with the electron microscope, fluorescence microscopy, and other methods of observation or illumination, the book does not, as its title might suggest, concern itself so much with examining material microscopically as with preparing it or examination. It is in fact a very valuable encyclopaedia of histological methods, listing alphabetically stains and other reagents and materials with the appropriate methods for them, each being described succinctly, often with references to original papers for further information. It deals with rather more than histology in the ordinary sense, since a good deal of space is devoted to the direct observation of living tissue, and instructions are also given for demonstrating bacteria, protozoa, fungi, and certain animal parasites not only in tissues but in body fluids. Its scope on the histological side is wide, including several columns on the microscopical location of vitamins, and several pages on the use of radio-active isotopes as tracer substances. Not only methods but a good deal of underlying theory come in for consideration: the qualities of things are explained, and purely technical items are interspersed with sections on such theoretical matters as oxidation-reduction potential. Introductory chapters deal with the choice of methods in a wider sense, with laboratory organization and the standardization of stains.

This should be a very valuable bench book to several kinds of worker: for anyone with a true pride in beautiful microscopical preparations it offers many possibilities which he will be anxious to explore.

## MAXILLO-FACIAL INJURIES

*Supplement to the Dental Treatment of Maxillo-Facial Injuries.* By W. Kelsey Fry, M.R.C.S., L.D.S.; P. Rae Shepherd, L.D.S.; Alan C. McLeod, D.D.S., L.D.S.; and Gilbert J. Parfitt, M.R.C.S., L.D.S. With Section on Fractures of the Middle Third of the Face by A. H. McIndoe, M.S., F.R.C.S., F.A.C.S. (Pp. 494; Illustrated. 21s.) London: Blackwell Scientific Publications Ltd. 1943.

A review of the parent book to this volume appeared in the *Journal* on June 19, 1943. The supplement contains the case histories and many photographs and radiographs of the most instructive of the cases that have been under the care of the team of dental surgeons at the clinic at East Grinstead. These two books present the most comprehensive treatise on the subject of any published work since the war, and praise must be given to the authors not only for their painstaking conduct and treatment of the cases they have looked after but also for the general conclusions and principles of the treatment which they have been able to lay down for the guidance of dental surgeons who are also undertaking this work.

The authors cover a wide field. To the dental surgeon who has not had the opportunity of treating cases arising from the war, but who occasionally sees civilian fractures of the mandible, the most useful contribution is the insistence on the separate cap splint method whenever there is any displacement, and the cases described show the great advantage of this over the more universal method of using the prearranged cap splint. The difficulties of the edentulous posterior fragment are well reviewed, though the methods employed are complicated and require the facilities of a specialized hospital. Mr. McIndoe contributes a section on the fractures of the middle third of the face, and the book ends with cases illustrating first-aid treatment and certain complications.

The whole text is simplified by the really excellent photographs, showing not only the progress of the patients but the details in the construction of the various appliances used.

## Notes on Books

Dr. R. D. LAWRENCE's book *The Diabetic Life*, first published in 1925, has now reached its 13th edition (J. and A. Churchill; 10s. 6d.). A Wartime Supplement, occupying the first thirteen pages of text, deals with the problems and special difficulties concerned with food rationing and distribution of insulin which the war has imposed upon the diabetic and his doctor. In his preface Dr. Lawrence writes: "By constant revision this book had become, I felt, rather a patch-work affair. So now it has been rewritten, and I have pruned much dead wood and ingrafted fresh in this edition. Its main object is still to be a practical guide in the treatment of diabetes, and theory is kept to a minimum."

The first comprehensive set of recommendations on post-war housing was published on March 24 in the Scottish Housing Advisory Committee's report *Planning Our New Homes* (H.M. Stationery Office; 3s.). The committee, under the chairmanship of Mr. Joseph Westwood, M.P., Joint Parliamentary Under-Secretary of State for Scotland, was asked in 1942 by the Secretary of State to report on the design, internal planning, standard of construction, and layout of new houses and on the provision of furniture by local authorities in municipal houses. This report was presented to the Secretary of State in November last, and Government action on a number of urgent recommendations has already begun. The committee recommends a "three-stage" programme to meet the problem of Scotland's housing needs. The bulk of this report is devoted to a long-term post-war housing policy. It recommends radical improvements in standards of living space in houses of all types, and insists that very great care should be taken to make the house comfortable and convenient.

The report on the work of the League of Nations in 1942-3 by the Acting Secretary-General has now become available in London (George Allen and Unwin, 40, Museum Street, W.C.; 2s.). It reviews the manifold activities of the League in wartime and in preparation for the post-war period. It shows the important work being done, even in wartime, by the international organizations. The fact that the headquarters of the League are situated at Geneva has given it the opportunity of observing much of what is taking place in Europe; and its branches at Princeton, U.S.A., and in London bring it into direct relation with a variety of technical questions closely concerned with current events. The work performed and the publications issued in regard to economic and financial questions, refugees, epidemics, health, nutrition, and narcotic drug traffic are of outstanding value.

## Preparations and Appliances

### ANAESTHETIC REQUISITES

Major J. FRAULO, R.A.M.C., writes.

To-day, and even more so in the coming months, the need for speed in the preparation of anaesthetics is obvious. An operating period consisting of numerous short cases can be completed much more quickly and easily if the anaesthetist has all his material ready at hand.

Since pentothal is used in the majority of cases, the devices illustrated herewith were made to facilitate the anaesthetic procedure. They have been in use for over a year, and since they can be made of wood in a short time by any amateur carpenter,

and since they can be used by any trained orderly, it was thought worth while to publish them.

Fig. 1 shows an ordinary block of wood drilled to hold five or six ampoules of pentothal. After filling one ampoule with water, the orderly transfers it to the hinged wooden block shown in Fig. 2. This hinged block should be weighted at the lower end so that the ampoule is normally held in a vertical position. When filling, the ampoule is tilted to the required angle, and the entire content is sucked up with ease. Fig. 3 is merely a wooden rack on which several fully charged syringes are laid.

These devices should be of assistance in any clinic where intravenous therapy is employed—e.g., varicose veins and venereal disease.

## THE OPHTHALMIC SURGEON AND THE OPTICIAN

BY

J. P. SPENCER WALKER, M.A., B.M., B.Ch.

*Hon. Surgeon, Sussex Eye Hospital, etc.*

### The Problem

Owing to circumstances which need not be gone into now, for we must look forward and not back, a curious and difficult situation confronts us. In the care of the eye the public find that there are two main groups who offer their services—namely, the ophthalmic surgeons and the sight-testing opticians. I need not go over once more the well-trodden ground of the rival groups, but will content myself with suggesting that up to now our approach, as medical men, to this problem has been wrong. The vast majority have said, or have not contradicted those who have claimed to be their spokesmen, that they will have nothing to do with the sight-testing optician, and all plans that have been tried or suggested have been framed in opposition to him—for example, the National Eye Service sponsored by the National Ophthalmic Treatment Board. This implacable attitude has got us nowhere. One reply to this attitude has been an attempt by the sight-testing opticians to get the Government to form a Register; and another is that if sight-testing by opticians is abolished, men who have taken considerable trouble to study optics and to work for a diploma will lose their means of livelihood. They have made themselves skilled in one occupation; what are they to do if they may not exercise their skill?

Our problem is therefore, How can we give employment to these men, and at the same time give the best service to the public? Can we produce a plan, which can be used whatever form the medical service of the country may take? I submit a plan for consideration.

### The Plan

The ophthalmic surgeon has his well-defined abilities and duties, and the optician his, and there is no essential need for them to be in opposition; but rather they should be, and really are, complementary to each other. The ophthalmic surgeon is concerned to a large extent with the physiological and pathological defects of the eye, and the optician with the appliances used to correct certain of these defects. Thus in a well-ordered scheme both of them should be able to play their part without trespass.

In the plan which I am putting before you the following persons will have their place: the ophthalmic surgeon, the optician, the orthoptist, and the nurse. First we must consider registration. The ophthalmic surgeon is provided for already in his qualification and registration as a medical practitioner. I suggest that the optician in future should receive a diploma from an "Ophthalmic Opticians' Council," which should be composed of opticians and ophthalmic surgeons (in a proportion to be settled later, when the principle of the plan has been accepted), who will be responsible for the training and examination for the diploma as well as for registration. On receiving his diploma the optician will become a medical auxiliary. At first an optician holding a diploma from a body now in existence would be registered by the "Council," but after the starting of the new plan these bodies would cease, and all new candidates would receive their diplomas from the new Council. The orthoptist trainer or orthoptist already has her diploma granted by the Orthoptic Board, which is composed of orthoptists and ophthalmic surgeons. She becomes a medical auxiliary on registration, and this arrangement need not be altered. The nurse likewise is already provided for in this respect.

Here then is our team. Under this plan a patient will visit an ophthalmic surgeon, who will examine him. The refractive error may be found by either the surgeon or the optician, acting as a refractionist, according to the nature of the case or the direction of the surgeon. In either case the optician will add the frame measurements, etc., to the prescription, and the type of frame selected. The completed prescription will be sent to the manufacturer. The spectacles, when ready, will be sent to the optician, and the patient asked to call for the final fitting and adjustment, thus giving the ophthalmic surgeon an opportunity of checking the glasses as well, if desired.

Should the surgeon wish to have an orthoptic report, or prescribes orthoptic training, his orthoptist is there ready. Or there may be some minor surgical procedure needed, such as the removal of a tarsal cyst; then the nurse is there to assist. I do not wish to go into detail, but to confine myself to the principle and outline of the plan. If the principle is accepted, then the details can be filled in, and the duties of each member of the team assigned.

### Argument in Support

From this brief outline it will at once become apparent that have employed all who are in any way connected with the practice of the treatment of the eye, and have divorced those employed from any commercial interest. I also maintain that, though the optician status will be enhanced, and he will have gained much that he present desires—namely, registration and a true recognition—this we have been accomplished without lowering the position of the ophthalmic surgeon. Not only will such a scheme give employment to ophthalmic surgeons and opticians but it is obvious that the number of each will have to be increased, for everyone who wishes to have his eyes examined will go to them and not to a "shop." This, then, will answer the two problems which have been put forward from time to time—namely, the employment of opticians in the "shop" and sight-testing are abolished, and the relief of the ophthalmic surgeon from that type of work, which some, perhaps erroneously, consider hardly within his province.

Such a scheme will obviously make it necessary to change the accommodation employed at present by most ophthalmic surgeons. But that perhaps will not be a disadvantage. Possibly "clinics" could be formed, where all the local ophthalmic surgeons share a common "waiting-room" and each had his own consulting-room which would provide accommodation for the optician and the orthoptist. If possible these might be a part of, or an annex to existing ophthalmic hospitals, or the eye departments of general hospitals. But such developments should not be considered in the present paper.

The opponents of any form of recognition or employment of opticians say that if we have anything to do with opticians we shall be in the same position as the dentists. This statement is ill-considered, for the position of dentists and ophthalmic surgeons cannot be the same unless, at some future time, the former are compelled to be registered as medical practitioners as well as dentists. Also in this plan the optician will be a medical auxiliary, and will not be absorbed into the ranks of the ophthalmic surgeons, which would be impossible, for he is not, and will not be, a registered medical practitioner. It is a pity that people make this kind of statement without thinking, for they not only prevent themselves from approaching a problem with an unbiased mind but they influence others who accept their statements without due examination.

This attitude of hostility is born of fear—fear of their rival, and fear that their case is weak. It is also born of a reluctance to face facts. Opticians do exist. All this fear is unnecessary, for there is work for all. Let any ophthalmic surgeon count how many opticians of all kinds there are in his own district or town, and let him assume that they make a sufficient income to keep their "shop" open, and then let him remember that under this plan every member of the public needing advice will have to be seen by the "team"; then having done this, I cannot understand how he can say that there will not be enough work for ophthalmic surgeons, the opticians, and the rest; or that his position is "lowered." The orthopaedic surgeon is not lowered by his contact with the masseuse.

Under this plan there will be no dispensing and no sight-testing opticians as at present, but ophthalmic opticians, who will be registered medical auxiliaries; and, as there will be no "shop," the commercial aspect will not rear its ugly head. I maintain that the patient will have at his disposal a service such as he has not had up to now, and that this scheme can be adapted so that it can be used by any form of "National" Medical Service which may be introduced, whether part-time, or whole-time.

Since I started working out this suggested plan, and before its publication, Mr. Frank Heckford of Ryde startled some ophthalmic surgeons with a suggestion very similar to mine. I was in some doubt whether to proceed with "my" plan or not; but I decided that I would, because if two people say the same thing it may carry more weight than if only one says it. I wish therefore to make it quite clear that I do not want to rival him but to assist, and that I do not claim any originality, but merely that my ideas have been evolving for a long time, even before this present war. Mr. Heckford's suggestions have been labelled "revolutionary" as against "evolutionary," but even evolution must at times appear to be revolutionary; to acquire a prehensile nose strikes me as revolutionary, but it was evolved, apparently, in the elephant.

J. W. Howard (*Amer. J. med. Sci.*, 1943, 206, 735) records these cases of carcinoma of the duodenum in men aged 48, 65, and 80, one of whom it was associated with erosion of the superior mesenteric artery. The rarity of the condition is shown by the fact that of 10,340 cases of carcinoma of the intestines the incidence of carcinoma of the small intestine was only 1.47%. Of 163 cases of carcinoma of the small intestine the duodenum was affected in 37%, the jejunum in 35%, and the ileum in 28%. It is generally agreed that duodenal carcinoma does not follow pre-existing ulcer and is seldom associated with polyposis.

## AMOEBIIC DYSENTERY

Frank Hewlett, writing in the *New York Times* of April 1, 1942, on the fall of Bataan, stated: "It was malaria and dysentery—not Japanese tanks and dive-bombers, or bayonets—that told the final story." Such a statement is open to dispute, but there is no doubt that the control of transmissible diseases, and especially of tropical diseases, as in this war, as in many wars of history, affected the results not only of local engagements but of the campaign as a whole by determining the numbers and movements of the troops engaged. The two diseases referred to by Hewlett, malaria and dysentery—or more correctly three diseases, since we must distinguish between amoebic and bacillary dysentery—are often spoken of as the most important of the "tropical diseases." But their ravages extend far beyond the Tropics, and their control is to-day a matter of first importance on almost every front where our troops are engaged. Bacillary dysentery is by no means unimportant on the home front, as the mounting figure of notifications during this war has shown.

The causal micro-organisms and method of spread from man to man have long been known in the case of malaria and bacillary dysentery, and the knowledge thus acquired has been effectively applied. But amoebic dysentery is in a somewhat different case. In 1875 Lösch named an amoeba found in the stools of patients suffering from dysentery *Amoeba coli*, but whether this was the cause of dysentery was discussed inconclusively during the next eight years, largely because of failure to distinguish between the harmless *E. coli* and the pathogenic *E. histolytica*. Koch's discovery, in 1883, of their presence in sections of dysenteric ulcers and in the walls of liver abscess supported the view that at least certain amoebae were pathogenic. In 1886 Kartulis in Egypt found amoebae in 150 cases of dysentery, and in sections of the ulcers from twelve fatal cases. In 1899 Quincke and Roos described the cysts of *E. histolytica*, and found that cats were infected by swallowing the cysts, whereas the vegetative form was infective only when introduced directly into the rectum. The final proof of the transmission to man was supplied in 1915 by Walker and Sellards, whose careful experiments proved that, when cysts of both *E. coli* and *E. histolytica* were swallowed by human volunteers, a high proportion of the volunteers became parasitized; but in no instance did those successfully parasitized with *E. coli* develop dysenteric symptoms, whereas four of the eighteen parasitized with *E. histolytica* eventually did.

The causal organism having been described, and its power to infect man when swallowed in the form of a resistant cyst demonstrated, it remained only to establish how the parasite was conveyed from man to man. This final link has proved surprisingly difficult to establish: water supplies, food and food-handlers, flies, reservoir hosts, and direct transfer have all been suspected; but the organisms have not been found except associated with

flies, reservoir hosts, or man. There is evidence that viable cysts are passed by flies after feeding on infective faeces, and since they have been found thus infected in nature it appears reasonable to believe that they play an important part in the transmission of the disease. Although the disease occurs in dogs, cats, and monkeys, there is no reason to believe that any of these animals are of significance in maintaining the disease, and it is probable that man is the only important reservoir. The difficulty of associating the human carrier with the spread of the infection is probably due to the fact that parasitization is not necessarily associated with the development of dysentery, so that it is often impossible to trace the source of infection in an individual who develops symptoms of the disease months or even years after exposure. It is tempting to conjecture that infection takes place through the swallowing of cysts adhering to uncooked food substances or present in contaminated water, particularly since we have proof that, under favourable conditions, they can survive for a long time in these. We may recall the outbreak of amoebic dysentery in Chicago in 1933, when over a thousand persons became infected apparently through drinking contaminated water. But although much has been written little has been proved regarding the normal method of infection; anything which adds to our knowledge, and so helps to strengthen our control of the disease, is to be welcomed.

During 1940 and 1941 Dr. Grace Ivanhoe<sup>1</sup> undertook a thorough investigation of the continued high incidence of *E. histolytica* infection among some 130 children, aged up to 6 years, living in an infant asylum in New Orleans. The history of the constantly extending amoebiasis in this institution is somewhat remarkable. In 1931 9% of the children were infected. Annual inspections from that date onward showed a progressive, though irregular, rise to the year 1939, when no less than 84% of the children were infected. Examination of the hygiene system adopted in the institution at first brought to light no reason for this persistent parasitization; in all respects the institution appeared to be clean and well kept. The water and sanitary systems were examined by engineers and found to be perfect; the rooms were cleaned with daily dusting and thorough house cleaning once a month; the laundering was done on the premises in a satisfactory manner; and the children's playground and bathing and wading pools appeared clean and well tended. The bed linen was changed almost daily, and night clothes three or four times a week. Underclothes were changed every day, and more often if needed. The children had individual washcloths, towels, and tooth-brushes. The youngest children had individual toilet pots, and the older children small flush-closets. At this stage one or two points regarding hygiene which at first were thought to be satisfactory proved on further investigation to be defective. Thus, in theory all the children were taught the use of toilet paper, and the process of defaecation among the little children was supposed to be under constant supervision. In practice it was found that this supervision was insufficient. Only a small proportion of the children used the toilet paper, and their underwear was often soiled with faeces. Again, it was found that in practice the pyjamas, which were sup-

<sup>1</sup> *Amer. J. Trop. Med.*, 1943, 23, 401.

posed to be changed daily, were changed only twice a week unless grossly soiled, and, acting on the notion that clean pyjamas were issued daily, no arrangements were made for individual possession. Dr. Ivanhoe then went on to discover from what sources the escaped parasites were recoverable. In order to do this two methods were employed: the Foerst centrifuge was used to separate matter from water media, and NIH swabs were used to obtain matter for examination directly from objects. Then followed a laborious and prolonged examination of the material thus obtained. *E. histolytica* cysts were recovered from the hands and from the soiled underwear of the older children, from the dust at the bottom of the laundry chute, from the damp sand in their play-box, from the water in the wading and bathing pools after the children had left them, and from the concrete floors of both wading pools. This intensive survey reaped its just reward. Armed with the knowledge of the source of infection, the sanitary authorities thoroughly cleaned the home by steam spray twice in eight days, and then again after mass treatment of the inhabitants had been completed. "Four weeks after completion of the treatment the examination of one specimen from each of the children by means of the direct faecal film and zinc sulphate centrifugal flotation technique indicated that not a single stool specimen was positive." The author suggests that these results indicate that the use of live steam to sterilize the environment, together with anti-amoebic mass chemotherapy, constitutes a simple and practical means of controlling amoebiasis in institutions.

### UTTERLY MISTAKEN

Speaking on the National Health Services proposals at Birmingham last week, Mr. Willink, Minister of Health, concentrated on what he called "two utterly mistaken ideas." The first was an idea held by doctors that the Government's proposals would end in converting the medical profession "into some sort of State-controlled and regimented service." The second was that these proposals would "ruin the voluntary hospital movement." Mr. Willink straightway said that nothing could be further from the truth, and he personally would not be party to any proposals which would have such an outcome. "I know that variety and professional freedom are the life-blood of any great profession—variety of personality in it and of individual professional method, scope for private enterprise in the best sense of that term. I know that a profession needs these things . . . if it is to attract the right people and to keep on achieving the highest results." In the new service, he said, doctors must be free to do their professional work in their own individual ways. There should be no risk of their becoming units in a machine, but they should "remain individual professional people in individual and personal relationship with those who seek and want their professional care."

As our correspondence columns with mounting emphasis are beginning to show, the medical profession at large is indeed anxious on these points, and, so far as it goes, will welcome the reassuring statement Mr. Willink has made. While our negotiators might reasonably expect to obtain

a sympathetic hearing from a member of a great profession which itself shows no desire to be regimented, must nevertheless face realistically the evidence present to us in the White Paper, and in the pictorial edition of at Charing Cross Underground Station. The prominent feature in the exhibition set up there about three weeks ago is a large-scale model of the health centre, the place where "to-morrow's doctors will work" and, as a diagram, shows, for a salary. But soft words butter no parsnips, and, with all respect to the Minister's assurance, it is not easy to see how in the long run general practitioners of this country can escape regimentation and control by the State in a complete service paid out of the public funds and based upon health centres owned by local authorities. The Minister believes that the good features in private medical practice do not depend upon the charging of fees, and that the freedoms doctors cherish could be kept even though the method of payment is changed. It is not so much a question of fees as against salary—although payment by fees has the virtue of stimulating a man to keep on his toes—as the relationship between the body that pays the salary and the person who accepts it. He who pays the piper calls the tune, and if the paymaster turns out to be a Government Department (or its autocratic Central Medical Board), or a so-called democratic local authority, then doctors rightly tremble for the future of their ancient profession.

Mr. Willink was emphatic in denying that it was the intention of the Government to harm the voluntary hospital movement. "It is," he observed, "the very essence of our proposals for the hospital service that it should rest on both the existing hospital systems carrying on side by side. . . . We are proposing that the voluntary hospital should remain, as they are now, self-governing and independent institutions." The Government did not propose that the voluntary hospitals should be taken over by local authorities. The voluntary hospitals would take part in the new service as free organizations, "entering into a contract with a public authority to perform certain services, for which they would receive payment from both the Exchequer and the local authorities." The Government did not intend to pay the whole of the cost of the services rendered by the voluntary hospitals, because if they did "voluntary support would no longer be needed." Many regretted the disappearance of the contributory schemes, but they could not restrict the "new universal service" to enable these schemes to continue.

The first reaction of many to the White Paper was to give it a cautious welcome, and this we must extend to Mr. Willink's statement last week—but cautiously nevertheless.

### TREATMENT OF SHOCK

Laboratory workers on traumatic shock may study conditions directly related to war or civil injuries in man, such as haemorrhage, burns, or crushing injuries. On the other hand, techniques may be used which have no counterpart in human injury, such as histamine or adrenalin poisoning, intramuscular hypertonic salt injections, etc. The latter indirect techniques serve as valuable controls on the direct methods, and analyses of the results often provide helpful clarification of the nature of various phenomena of wound shock.

Muirhead, Kregel, and Hill<sup>1</sup> produce "shock" by an direct technique. A dog's hind limb is frozen. In three hours after freezing the "permeability" of capillaries is creased locally with gross swelling of the limb due to asma transudation. Haemoconcentration and lowering blood volume result, and the animal dies a few hours ter in "shock." The condition may best be compared ith the early acute stage following burns or crushing juries. Their experimental observations on therapy are chiefly as follows: (1) Amputation of the limb after haemoconcentration has developed, but before hypotension sets in, fails to save life. (2) An infusion of approximately 30 c.cm. three-times concentrated plasma given in divided doses during the fourth hour also fails to prevent a fatal outcome. (3) If amputation is combined with the plasma infusion, haemodilution is achieved and survival usually follows. A simple interpretation of these main findings is easy to suggest. Oligoemia results from plasma transudation in the injured limb. Once haemoconcentration has developed amputation can have little effect in correcting the circulatory state. A single plasma infusion may also exude into the tissues of the injured limb. The same phenomenon may be seen in man in burns and crushing injuries, in which multiple serum or plasma infusions are often required to restore and maintain the blood volume. If the injured limb of the dog is removed the infused plasma is retained, with lasting benefit.

In the animals which died after experiments (1) and (2) the pathological changes were of great interest: hyaline casts in the medullary tubules of the kidneys and centrilobular necrosis of the liver bring to mind the lesions seen in both burns and compression injuries. While the changes in the liver may be explained by the low flow of blood and consequent tissue anoxia of hypotension, the renal damage and other tissue changes, e.g., in lungs and suprarenals cannot be so readily accounted for. There is undoubtedly re-circulation through dead tissue in the frozen limb, and, in addition to loss of plasma, autolytic products diffuse into the general circulation with possible toxic effects on various organs and tissues. This work seems to open up a new method for study of the remote effects of tissue autolysis after necrotizing injury.

Some interpretations by the authors are open to question. When the haemoglobin fails to be diluted as much as expected after plasma injection they interpret this phenomenon as "mobilization of corpuscles." A more rational explanation would be loss of infused plasma from the circulation. The work of Sharpey-Schafer and Wallace<sup>2</sup> on man indicates that quite massive shifts of protein-containing plasma may take place into and out of the circulation with extreme rapidity. The bogey of "trapped" corpuscles in various parts of the circulation in shock is fortunately becoming a rather threadbare shadow of its former self.

### BOOKS FOR PRISONERS OF WAR

Readers who have sent gifts to the Medical War Relief Fund for the special purpose of providing medical books for British doctors who are prisoners of war will be glad to know that the money contributed has not been lying idle. On the contrary, the greater part of it has already been spent, and the time is approaching when the balance remaining will be exhausted. Requests continue to arrive from the prison camps, and the letters from prisoners who have already received gifts of books leave no doubt as to the value of this form of help and the gratitude with which

it is received. The Committee is anxious that the primary object of the Fund—the relief of financial distress—should not suffer through the diversion of money to the special purpose of providing books for prisoners of war, and only specially marked donations are used for the latter purpose. The Committee will be grateful if subscribers, while continuing to support the main object of the Fund, will send additional contributions marked for the provision of books. The need is becoming urgent. Cheques should be made payable to the Medical War Relief Fund and addressed to the Honorary Treasurer of the Fund at B.M.A. House, Tavistock Square, W.C.1.

### ABSENTEEISM AND PREVENTION OF FATIGUE

The second pamphlet published by the Industrial Health Research Board on conditions for industrial health and efficiency<sup>1</sup> is divided into two parts. The first relates to "Absence from Work" and the second to "Prevention of Fatigue." Both subjects are dealt with in a simple but most instructive manner, which can easily be understood by anyone, factory worker no less than factory manager. The pamphlet is attractively produced, like its predecessor (which dealt with "Ventilation, Heating, and Lighting"), and it is likely to command a wide circulation. The information is to some extent based on investigations made in sixty factories, one of them having 25,000 employees, and it is concluded that under wartime conditions the absenteeism is almost certain to be greater than in peacetime, a reasonable absence amounting to 6 to 8% for men and 10 to 15% for women. Factories vary much in their accessibility, some of the large new factories in particular being a long way from the homes of the workers, and transport overcrowded and unreliable. Married women may show three times as much absence as single women, owing to the extra calls on their time for shopping, housework, and the care of children. Health is often affected by factory conditions, mental no less than physical, and these conditions can generally be improved in various directions. The boredom set up by the repetition work on which so many munition workers are employed can be reduced by the introduction of a 10-minute break in the middle of each work spell, and by occasionally relaying lively music; it is also well worth while to try, so far as possible, to see that the job fits the person, and to arouse interest by letting the workers see the finished product they help to make. Health can be improved by the workers, when off colour, seeking advice from the works doctor, and in buying varied and nourishing meals, while women with families should aim at half-time work.

The second half of the pamphlet discusses the relation between boredom and fatigue, and their influence on output. One of the most potent influences is the length of the working week, and the conclusion is reached that the weekly hours of work should not exceed 60 for men and 55 for women. For certain classes of workers, in particular for heavy manual workers and women with home duties, these hours are still too long. A week-end break is important, and working hours should be spaced over a five-day or five-and-a-half-day week. Workers suffering from the effects of cumulative fatigue should be given a rest of a week or fortnight at one of the country houses which have been taken over for this purpose. Thereby illness and breakdown may be avoided. It is stated that at present there are no signs that boredom or fatigue in industrial workers has reached dangerous proportions: but both are increasing, so safeguards ought to be taken.

<sup>1</sup> Arch., Surg., 1943, 47, 255.  
<sup>2</sup> Lancet, 1942, 1, 699.

<sup>1</sup> Conditions for Industrial Health and Efficiency. Pamphlet No. 2 H.M.S.O. 1944. (3d.)

The one adverse criticism we have to make concerns the date of the publication of the pamphlet. It would have been so much more useful if published some two years ago, there being practically nothing in its contents to preclude such a course.

## MEASURING INTELLECTUAL DETERIORATION

Intellectual deterioration is a suspected sequel of many organic cerebral and some purely mental disorders; indeed, it is said by some to be the main cause of maladjustment to life during recovery from a head injury or other cerebral accident. It is, however, by no means easy to determine by ordinary clinical methods the nature and degree of such impairment. If mental tests could give an objective answer to these questions they would be valuable in prescribing treatment and in recommending suitable employment; the progress of a case could be followed and a more accurate prognosis given. Moreover, a quantitative measure of intellectual damage after an injury might be a useful guide in the assessment of claims for compensation and pension. Of the test procedures at present in use for this purpose most require special knowledge and take too long to administer to be of use to the average doctor; on the other hand, it seems unlikely that any single test would give a reliable enough measure of such very complex material. Brevity and simplicity are of prime importance; the results should be capable of quantitative evaluation; and current opinion seems to favour a battery of short and simple tests.

Most of the published work on this subject records the qualitative abnormalities shown by tests of patients suspected on clinical grounds of organic impairment. Such abnormalities may be due to organic deficit, but it is dangerous to assume without statistical backing that all subjects showing similar deviations from the normal are also intellectually impaired. There is in this branch of research a need for carefully planned and controlled experiments; the great variability of normal performance in mental tests, both between different individuals and in the same person under different conditions, makes it more than usually hard to interpret the results of such tests in psychopathological states. Indeed Goldstein,<sup>1</sup> reporting the results of such work in patients with brain injuries after the last war, states that it is not possible to judge the subject's capacities by the end-results of the tests he uses—that it is not what the patient does but how he does it that matters; this may be an extreme view. The basic hypothesis on which most of the quantitative work in this field rests is that a person's vocabulary and other types of rote knowledge is less affected by age and degenerative cerebral conditions than more recently acquired information.<sup>2</sup> If, therefore, there is found to be a discrepancy between the score on a standardized vocabulary test and those on tests of active mentation, this discrepancy is assumed to be due to intellectual deterioration. Using this principle, Lidz, Gay, and Tietze<sup>3</sup> have compared the results of tests of patients suffering from organic deteriorating conditions with those of schizophrenics. As a measure of their subjects' capacity for active mentation they have used the Kohs block test,<sup>4</sup> which, they point out, has the advantage of being a well-standardized performance test singularly free from the influence of past experience. The scores on this test are compared with

those on the Binet vocabulary,<sup>5</sup> and it was found that the Kohs scores were significantly lower than the vocabulary in the organic than in the schizophrenic group. This finding is interpreted as showing that the thinking disorder of schizophrenics ought not to be included in the disabilities following damage to the brain.

The authors draw attention to the fact that their conclusions depend on the assumption that a normal control series would not show this discrepancy. If such prove to be the case, and if emotional factors as a cause of the discrepancies could be ruled out by examining a comparable series of psychoneurotics, the method they advocate might prove a valuable aid in the estimation of organic intellectual deficit.

## THE QUEEN'S NURSE

Charles Booth, in his *Life and Labour of the People of London*, remarked that it was "almost true to say that wherever a nurse enters, the standard of life is raised." Since the Queen's Institute of District Nursing was founded at Queen Victoria's first jubilee, the Queen's nurses have helped to raise the standard of life in a way not generally recognized. The visit of the Queen's nurse is not only effective in what she does for the patient's immediate need but in the atmosphere she brings with her and the example she sets. What the nurse says and instructs to be done is accepted by the patient, and the knowledge is passed on to family and neighbours. This has been a factor in social improvement perhaps more important than some of the other factors to which one commonly attributes the progress of the people towards healthier living. The Queen's nurse is different from the hospital nurse, not merely because the one has a domiciliary field of work and the other an institutional, or because the one is the guest of her patients and the other is the hostess, but because the nurse on the district, in addition to her three years' training in hospital, has spent a further six months in the study of the special problems of home nursing; and if she is the right type, as she generally is, she has great opportunity to give her patients advice beyond the matter of the immediate ailment.

A sixpenny illustrated pamphlet has now been published by the Queen's Institute (57, Lower Belgrave Street, S.W.1) to introduce the district nurse to a public which, though familiar enough with her navy blue uniform and badge, may not know very much about her work. She is organized through county and district nursing associations affiliated to the Queen's Institute. In towns her work is mainly general nursing; but in seventy towns midwifery is also undertaken, and midwifery forms an important part of the work in rural areas. In the midwifery service undertaken by the Queen's nurses in 1942 the maternal mortality rate was only 1.17 per 1,000 births. Some day, perhaps, the heroism of the home-visiting nurse in wartime will be commemorated. One incident is mentioned in this pamphlet. In the devastating air raids on Coventry the nurses' home was completely demolished, and the military authorities—perhaps not expecting to be obeyed—advised the nurse to leave the city. The nurses did nothing of the sort. They stayed on, living in an air-raid shelter and clambering about among the ruins to find their patients. On every housing estate in the replanned Britain there ought to be a nurses' house, as certain to be found there as the office of the estate agent or the manager, where one or more nurses could live. The general practitioner would be the first to welcome such an arrangement.

# AN IMPORTANT LOCAL ANALGESIC

● 'Anethaine' is a local analgesic with unusual and valuable properties, and is used in all forms of local analgesia.

In the effective dosage, the margin of safety is high. It has from 10-18 times more anaesthetic activity than procaine and is used in correspondingly lower concentrations.

Complete analgesic effect is of long duration, lasting from 1½ to 3 hours.

It has the very important property of high activity on surface application, and is thus the most suitable preparation for the anaesthetization of mucous membrane and wound edges prior to operative procedures or instrumentation, and in ophthalmology.

'Anethaine' is available in various packings for surface, infiltrative and spinal analgesia.

Powder ... 1 and 5 grams  
Solution 2% (external) ... 25 cc.  
Solution 1:10 10 x 0.1 gram  
Amprules (Spinal) 1% 6 and 100 x 2 cc.  
Dry Amprules (Spinal) ... 6 and 25 x 10 mg.  
Dry Amprules (Spinal) ... 6 and 25 x 20 mg.  
Infiltrance (Powder) ... 3 and 25 x 100 mg.

# ANETHAINE

BRAND OF AMETHOCAINE HYDROCHLORIDE

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRON 3434

## THE CONTROL OF SEPSIS IN BURNS BY THE IRRIGATION ENVELOPE TREATMENT

*A review of the number and character of war burns treated in various Service and civilian hospitals during the last year, demonstrates an outstanding fact very clearly. This is that sepsis is the bugbear of such burns, and if it can be eliminated then there are few complications which can arise.<sup>1</sup>*

*If more than thirty-six hours have elapsed since injury before the patient reaches hospital, the burned areas are infected and coagulation therapy is no longer safe. Again, apparently clean burns may become grossly septic beneath a pellicle which will be rapidly cast off as a result.<sup>2</sup>*

The IRRIGATION ENVELOPE TREATMENT offers a rational and efficient system of therapy which permits the continued control of infection while introducing at the outset the physiological conditions most favourable to the progress of natural healing.

The efficiency of this treatment derives from the Stannard Irrigation Envelope which occludes the damaged area, thus reducing the possibility of secondary infection to a minimum, and Electrolytic Sodium Hypochlorite which, in the strengths employed for irrigation, provides a non-toxic antiseptic solution with the complementary property of a lytic agent. In the presence of an actually established infection it is this lytic action of hypochlorite which has led to its designation as a 'chemical histoury'.<sup>3</sup> By this action the barrier of necrotic tissue and cell detritus, generally impermeable to bacteriostatic agents, is removed, thereby exposing the site of infection to the further action of the hypochlorite as an antiseptic.

### ELECTROLYTIC SODIUM HYPOCHLORITE

is preferable to chemical hypochlorites which tend to be caustic and are deficient in saline content. MILTON is recommended because it is standardized in strength of hypochlorite (1 per cent.) and stabilized so that it retains its effective strength indefinitely. MILTON is only faintly alkaline in the dilution used for routine irrigations (pH 8.89), and, after its chemical action is complete, leaves a residue of sodium chloride and water.

### STANNARD IRRIGATION ENVELOPES

The Envelopes are made of the finest grades of pure silk coated with synthetic resins by which they are rendered transparent, waterproof, impervious to the action of electrolytic sodium hypochlorite, smooth of surface and soft and supple in texture. They permit the patient to move the limb freely so avoiding the loss of function due to immobilization and without causing irritation or pain from the friction of the dressing. Irrigation envelopes are made in a wide range of styles suited to the varying sites of injury, and in a range of sizes which allows convenient application to all types of patient.

Telephone: Terminus 1361.

Telegrams: "Encigate, Kincross, London."

# DIPHENAN B.D.H.

(*p*-benzylphenylcarbamate)

Diphenan B.D.H. conforms with all the tests for Diphenan B.P.C.; it is an anthelmintic, highly active against threadworms and remarkably free from toxic effects. Some gastric disturbance may occur in a few patients during the first day or two of treatment, but, if administration is continued, tolerance is normally established. For successful treatment, adequate precautions must be taken to prevent reinfestation which readily occurs. The eggs of the parasite are air-borne and, therefore, are likely to be found in the dust throughout the house in which an infested patient lives. It is advisable, therefore, to treat all the occupants of the house and to continue treatment not only until every member of the household is known to be free from parasites, but until any remaining eggs have ceased to be viable.

*Details of dosage and other relevant information will be gladly supplied on request.*

## 'Sodium Amytal'

BRAND

SODIUM ISO-AMYL ETHYL BARBITURATE

## in Psychiatric Conditions

Many years of clinical experience have proved the value of 'Sodium Amytal' in disturbed mental conditions. Patients may receive effective doses with relative safety. Psychotherapy may be successfully employed in the "twilight" state which is induced. This method is recommended for treatment of hospitalized cases, but may be employed in private homes with adequate nursing supervision. Permanently good results may be obtained.

## REHABILITATION OF HEART CASES

MEMORANDUM BY CARDIAC SOCIETY

*The memorandum on the rehabilitation of cardiac patients printed below has been approved by the Council of the Cardiac Society of Great Britain and Ireland. It is signed by the chairman, Sir Maurice Cassidy, and the secretary, Dr. Maurice Campbell.*

Many patients, those with fractures for example, derive great help from efficient rehabilitation. Without it they may be handicapped for long periods; with it most of them may be enabled to undertake all activities and to resume their normal work. The success achieved in this direction has led to the suggestion that similar methods should be used more widely, and the Council of the Cardiac Society felt the time was opportune for expressing their views and bringing forward some questions for wider discussion.

Patients with heart disease are in rather a special category as regards rehabilitation. In the first place any activity, including walking or other forms of physical effort, must automatically increase the work done by the heart. If the patient is going to recover completely—e.g., after some temporary infection—cardiac recovery will often proceed *pari passu* with recovery from the infection and no more than simple graduated exercises may be needed to ensure it; in fact he may need limiting rather than encouraging in his rate of progress. In other cases complete recovery may be impossible and it may be most important that he should not return to his previous work and activity.

Further, the correct diagnosis of the condition of the heart and especially of the heart muscle, and the correct assessment of the cardiac reserve, are of fundamental importance, and harm may be done by too much or by too little activity at any particular stage.

## Limited Scope for Rehabilitation

In our opinion there is only limited scope for rehabilitation, as the term is now being employed, for patients suffering from organic cardiovascular disease. Physiotherapy and graduated exercise are of course useful but must be supervised by a doctor with special knowledge of heart disease. The main problem is the decision as to how much general activity should be allowed, and this depends more on the success of the doctor in charge in diagnosis and assessment of the patient's cardiac reserve than on the availability of skilled assistants in physiotherapy or occupational therapy. The need for suitable convalescent homes is of course generally accepted.

There are, however, cases in which the heart is temporarily under suspicion, which fuller investigation proves to be unjustified—e.g., systolic murmurs which the inexperienced may hesitate to disregard but the experienced are able to label as "insignificant." In many such cases all that is necessary is for an authoritative opinion that the heart is normal and that the patient is, therefore, capable of leading a full active life, but in others rehabilitation may be needed. There is also scope for rehabilitation in the case of effort syndrome, which is at least as common in civil life as under Service conditions, though here it may appear diagnosed as "cardiac anxiety state," "traumatic neuroasthenia," or "post-influenza tachycardia." But we suggest that the rehabilitation of these patients, whether by graduated exercises or by simple psychotherapy, should not be carried out at cardiac clinics, once it has been decided that there is no organic disease.

We suggest, therefore, that there should be more well-staffed and well-equipped out-patient cardiac clinics at general hospitals, preferably under the care of an experienced cardiologist. Here a correct diagnosis could be made, and the patient could be advised about suitable employment and be kept under observation when engaged in such employment. The help of the almoner's department would often be useful. If necessary the patients could receive specialized treatment that experience has shown to be more satisfactory in cardiac clinics, such as the treatment of auricular fibrillation with digitalis or of congestive failure with mercurial diuretics, or the control of symptoms of early angina.

## Work for the Partially Disabled

Special difficulties may arise in finding suitable work for patients with some permanent limitation as a result of heart disease, and this is a problem that should be discussed. Many such persons, especially the younger ones with rheumatic heart disease, are precluded from those occupations which are most appropriate to their condition—e.g., Civil Service, banking, and insurance. They are, therefore, forced to take less suitable work for which no medical examination is necessary and in which their health may break down. Alternatively, they are out of employment and the nation is losing citizens who might give valuable service for a considerable number of years.

We recommend that where a patient is fit for particular work his acceptance should not be impossible because he has valvular disease which precludes his joining an ordinary life assurance scheme; it

should be possible to make special arrangements for accepting such patients in some branches of the Civil Service, banking, etc.

Another difficulty is with the older patient who is beginning to be incapacitated by early signs of failure or angina or by such lesions as hypertension, arteriosclerosis, or myocardial disease which may lead to failure if his previous employment is no longer suitable. Such a patient would often be better at work and would like to be at work, but cannot find anything because he is not fit for the heavy work that he did before.

We recommend that there should be some industrial advisory board or Government Department through which arrangements could be made to ensure that these partially disabled patients could obtain suitable work, after, when necessary, appropriate special training. Often this would not be necessary and the patients' previous employers might be able to carry out the medical recommendations, especially if they were safeguarded against claims against them under the Employers' Liability Act in the event of a breakdown of an employee known to be suffering from heart disease.

The special care of rheumatic children is being dealt with elsewhere in a separate memorandum.

## Nova et Vetera

## EARLY BRITISH PHTHISIOLOGISTS

At the March meeting of the Section of the History of Medicine of the Royal Society of Medicine Prof. S. LYLE CUMMINS read a paper in which he dealt with five British workers who had given to the world epoch-making work on the aetiology, pathology, and treatment of tuberculosis.

Prof. Cummins dealt first with Richard Morton (1637-1698), who published his *Phthisiologia* in 1688. Morton was one of the first to appreciate the importance of phthisis and the necessity for carrying out post-mortem examination on the bodies of such patients. He entered the church as a young man and was ejected from his living in 1662. Thereafter he studied medicine and eventually became a Physician-in-Ordinary to the King. Morton recognized that, in the acute tuberculosis which was common in his day, the lungs might be full not only of ulcers but also of tubercles. In his post-mortem examinations he saw these tubercles in the glandular parts. In describing the symptoms and signs of phthisis Morton noted that the following were early features: The disease is more hereditary than any other; spitting of blood; continued loss of appetite; frequent catarrhs without obvious cause. His views on treatment were essentially rational. He recommended prudence in eating and drinking, early to bed and sound sleep, moderate exercise, an avoidance of strong purges, the maintenance of a cheerful disposition, and the enjoyment of "an open, fresh, kindly air."

Benjamin Marten published his *New Theory of Consumptions* in 1772 and went far to anticipate the subsequent discoveries of Villemin and Koch. Marten brushed aside all theories of causation which depended on the acidity or alkalinity of the humours, and suggested that "the original and essential Cause . . . may possibly be some certain species of Animalcula or wonderfully minute living creature" which are either carried to the lungs by the blood or are generated there from ova. It is important to note his suggestion that these animalcula "are for the most part either conveyed from the Parents to their Offspring or communicated immediately from the diseased Persons to sound ones. . . . The last way, which is properly called Infection, we may conceive to be the more reasonable." This is one of the brilliant flashes of inspiration which were lost in darkness for many years.

In dealing with William Stark (1741-1770) Prof. Cummins noted that, although he was a physician of St. George's Hospital, the hospital has now no record of his work there. Stark studied first in Glasgow and Edinburgh. He was the first to observe in the diseased body the method whereby the tuberculous nodules could cause advanced disease and death. He described the avascularity of the tubercle and made a very minute study of cavities. Small cavities are "quite shut up"; larger ones—which he called "vomicae"—frequently communicated with bronchi. Stark also described the thickening of the pleura over superficial cavities. There is no doubt that his work was of paramount importance in unravelling the pathology of phthisis.

George Bodington (1799-1882) belonged to an old Warwickshire yeoman family, and he settled in practice in the county. In 1836 he became the proprietor of a private asylum, and four years later he published his pamphlet on *The Treatment and Cure of Pulmonary Consumption*. Bodington was the first to suggest open-air treatment. He had a house for the purpose, and his treatment consisted of good fresh air, a sufficiency of wholesome food, and a definite quantity of wine, with a sedative (opium) to ensure sleep and to calm apprehension when necessary. He suggested and practised the specialist treatment of tuberculosis. At the time the medical profession howled Bodington down, but he now stands for the system which is at last tending to control tuberculosis.

Prof. Lyle Cummins also referred to the brilliant suggestion which William Budd of Bristol made, in 1856 that phthisis is a specific zymotic disease which can be disseminated by specific germs in the tuberculous matters of sufferers. Budd did not publish his letter to the *Lancet* on this matter until 1867, and by that time Villemin was following the same trail to a successful issue.

## Reports of Societies

### ANAESTHESIA FOR ABDOMINAL OPERATIONS

A combined meeting of the Sections of Surgery and of Anaesthetics of the Royal Society of Medicine was held on April 5, Sir JAMES WALTON presiding, for a discussion on "Anaesthesia and Analgesia in Abdominal Operations."

Surg. Rear-Adml. G. GORDON-TAYLOR opened by drawing a half-serious, half-humorous picture of the modern anaesthetist, whom for versatility he compared with Leonardo da Vinci and the Admirable Crichton. Besides the large amount of technical knowledge and resourcefulness demanded of him, he was expected to be able to radiate comfort to the patient and to utter words of encouragement in simple language to the surgeon. Anaesthetists, if not a group of supermen, were in his experience as a surgeon the most loyal and delightful of colleagues.

The methods, vehicles, and agents of anaesthesia were legion, and there were few surgeons who had experience and time to evaluate the ever-changing kaleidoscope of anaesthetic activity. The task was not made easier by the absence of any exact criterion for judging the claim of a particular medium to be better or the best. It might have been thought that the figures for operative mortality would provide an index for appraisal of the value of a particular form of anaesthesia, but operative mortality depended on many factors besides the anaesthetic and the mode of its administration. Much had been heard of "balanced anaesthesia," and it might be thought that herein lay the talisman to solve the quest for the best anaesthesia. "Balanced anaesthesia" was certainly a euphonious term, one which must create confidence and expectation in the bosom of the patient, but it was surely only a novel name for an old concept and practice, with this difference, that the pharmacological admixture had now run riot. The former generation of workers was apt to be forgotten. Forty years ago George Crile first toyed with the idea of the shockless operation. Since 1914 the speaker himself had been an adherent of the Crile school, and he continued on the same lines with the loyal co-operation of his anaesthetist colleagues. He would not enter upon a comparison of methods which were perhaps not really comparable, but rather give an account of his own experience in abdominal surgery. Many abdominal operations, especially the surgical treatment of malignant tumours of any size in the abdominal wall, must be extensive, and without regional anaesthesia great shock would be produced. So far as the abdominal wall was concerned, he had contented himself with the rectus block along the outer border of the muscle and the lower costal margin, and thus obtained the degree of relaxation of the abdominal wall that he desired. During the last twenty years he had used novocain almost entirely. Novocain had the disadvantage that its duration was not unlimited (and the average gastrectomy took him an hour and ten minutes). In addition to the regional and solar plexus block he liked to keep his patient slightly under general narcosis with a little ether and chloroform, never getting the patient deeply under. He always had a bias against a mask over the patient's face for any long period. For "bad risks" and cases with severe haematemesis, operation should be carried out under local and splanchnic block without any general narcosis.

Adml. Gordon-Taylor then gave some statistics of various surgeons. He mentioned the figures of Yudin of Moscow for gastro-duodenal resections and acute perforated ulcer, carried out under high spinal anaesthesia, 331 cases, with 21 deaths (6.3%). Duval in Vienna claimed 125 gastric operations for ulcer, and Haas of Munich 250 such operations, in each case with no deaths, regional and splanchnic anaesthesia being employed. H. W. L. Molesworth in this country reported 119 gastric operations (ulcer) under local and splanchnic anaesthesia, with 3 deaths (2.5%); W. J. Ferguson at West Middlesex Hospital, 202 with 7 deaths (3.5%); and Norman Tanner at St. James' Hospital, Balham, just under 100 with 4 deaths, and a later series of 120 with 1 death, which last remarkable record he attributed partly to the prophylactic use of sulpha-

pyridine. Adml. Gordon-Taylor mentioned 794 of his cases over a period of 18 years, in which there had been 52 deaths; he had not thought the death rate was as high as 6.3% until he came to work it out, but he was comforted by the fact that in a later series, 1938-44, of 148 cases including gastric and duodenal ulcer of all types, there had been only 4 deaths (2.7%).

In many regions of the abdomen the question of anaesthesia counted less than other factors. For operations on the gall bladder—simple cholecystectomy—he had never used an anaesthetic except general inhalation and regional. With obstructions of the common duct it was important to avoid ether and chloroform, and he used gas-and-oxygen supplemented by good regional and solar plexus block. In carcinoma of the colon the actual choice of anaesthesia mattered very little; the skill and methods of the surgeon were much more important. Nothing could vie with local anaesthesia in the case of strangulated hernia. He added a few words on anaesthesia in war. An old slogan of his was, "In a man wounded in the belly spinal anaesthesia is certain euthanasia," and he did not depart from that opinion. Conversations with surgeons recently returned from the Mediterranean confirmed their truth in ether. He was a little surprised that the work of Crile during the last war with gas-and-oxygen and regional anaesthesia had not been repeated. Crile's recovery rate in the last war far exceeded that of any other abdominal surgeons on the western front. But the figures from surgeons in the Mediterranean did not fall far short. In the Navy the problem was slightly different. On H.M. ships there was always a risk of explosion, and therefore, in the smaller craft at any rate, ether anaesthesia seemed to be forbidden. Here he acknowledged the help of the Oxford vaporizer machine, which had permitted operations on some of the rescue ships to be successfully performed.

### Abdominal Relaxation

Dr. FRANKIS EVANS said that anaesthesia in abdominal surgery might be considered essentially in terms of relaxation. No surgeon could work properly inside the abdomen unless the muscles were adequately relaxed. As Lord Moynihan used to say, "The surgeon should never need to fight the patient." The anaesthetist's duty was to master the various techniques he might be called upon to use. Abdominal relaxation might be obtained in many ways. The choice of inhalation anaesthetics was far greater now than twenty years ago. Ether was an old friend if a somewhat malodorous one. It had been stated that from 65 to 72% of patients vomited after ether anaesthesia. It was wrong to give ether to a chronic bronchitic. Chloroform was, of course, more toxic than ether. Gas-oxygen alone did not give abdominal relaxation. Where ether was used with gas-oxygen to give relaxation the gas-oxygen was, of course, only the vehicle. Cyclopropane was "the answer to the anaesthetist's prayer," but he had not always been able with cyclopropane to obtain the degree of relaxation required, and had added a little ether—but a little ether went a long way. Describing the technique of the adrenaline drip, he said that this should be in the strength of 1:250,000 in normal saline. It was advisable not to add the adrenaline to the saline until the drip had got going; in other words, one should not start with adrenaline straight away. The average rate of drip was 50 to 60 a minute. The drip should certainly be continued for two hours, perhaps longer. The longest time he had carried out an adrenaline drip was something like 18 hours; the patient was very ill, and the procedure proved satisfactory. Intravenous pentothal had proved of great use, but he did not recommend it for the "desperate risk."

Mr. NORMAN LAKE said that the use of anaesthesia was twofold: to prevent the patient feeling pain, and to enable the surgeon to perform the operation with facility. The modern anaesthetist in his proper desire to achieve the first object had sometimes neglected the second. Many post-operative sequelae laid at the door of the surgeon might be related rather to the anaesthesia. Some complications were said to be due to "rough handling" of the viscera, but it should be inquired why rough handling was necessary. Unsatisfactory anaesthesia with a rigid abdominal wall might be the most important factor necessitating these manoeuvres summed up in the phrase "rough handling." Speaking of the procedure

in the use of spinal anaesthesia, Mr. Lake said that it was a psychological error to ask the patient whether he could feel anything. The anaesthetist should, without such questioning, be fully appreciative of the patient's feelings. The atmosphere should be one of confidence in the anaesthetic and in its safety. This was best obtained by a matter-of-fact attitude on the part of all concerned rather than by repeated reassurances. One disadvantage of spinal anaesthesia was that it permitted the patient to hear all that was said. The walls of the operating theatre should be placarded with warnings against "careless talk." Freedom of speech was all very well in the Atlantic Charter, but it had no place in spinal anaesthesia. He thought the advantages of high spinal anaesthesia outweighed by far its disadvantages. He had used it for years in gastrectomy and similar operations with increasing satisfaction.

The remainder of the discussion was largely a relation by speakers of the details of their particular methods or their modifications of classic methods. Dr. A. H. L. BAKER spoke of the advantages of regional anaesthesia, especially in the better relaxation obtained as compared with general anaesthesia. Dr. ETHERINGTON WILSON said that spinal anaesthesia took a great deal of "getting used to," and the technique must be controlled. He described his own technique, in which he used spinocaine with better results than with nupercaine. Mr. HAROLD DODD and Dr. H. W. L. DALE mentioned modifications which they employed in their practice. Sir JAMES WALTON commented on the slightness of the reference in the discussion to general and complete anaesthesia.

In a general reply Mr. NORMAN LAKE said that on listening to the various speakers he could not help drawing an analogy with our bombing policy in the war. When we wanted to destroy railways in Germany we did not send out individual bombers to cut up a little bit of line here and a little bit of line there, but we sent, in the aggregate, a smaller number of bombers to pinpoint some notorious place such as a marshalling yard. Regional, splanchnic, and local anaesthesia represented a distribution of forces in order to reach the individual railway lines: but with spinal anaesthesia one was actually "bombing the marshalling yards at Hamm."

## PHILOSOPHY OF THE PECKHAM EXPERIMENT

The philosophical basis of the Pioneer Health Centre at Peckham was discussed in a lecture to the Science (Research) Society, a body of young biologists, by Dr. INNES H. PEARSE, one of the medical directors of the Centre.

Dr. Pearse began by pointing out that in the physical or chemical analysis of an organism, which involved the separation of its elements, some quality which she called "liveness" escaped. The pieces of Humpty Dumpty could never really be put together again. The study of the living organism of society demanded a different type of procedure, a creative synthesis, not the cracking of the shell of the egg but the getting of a hen to sit upon it. She mentioned the inseparability of the organism and the environment. All increase in the organism might be said to take place by engulfment of the environment; and once engulfed, a mutual synthesis took place, a shuttle-like process, between the organism and the environment. It was within the range of probability that what was being studied was in fact a mutual evolution of organism and of environment—an environment which was as organismal as the organism itself.

Those who undertook a biological experiment had first to decide what unit to adopt, whether the simplest of organisms—the amoeba—or man; and the Peckham experimenters chose man, for it was the function of the organism they desired to study, and man had the greatest differentiation of function. But they did not take the individual as the basis of observation, they took the mated pair, reaching full maturity in parenthood. Dr. Pearse suggested that in parenthood there was a new creative synthesis, not only in the physical realm but in the whole realm of function which was touched by man and woman. She instanced the parallel of the pair of eyes, each eye in a sense complete and functioning by itself, but having some added aptitude—namely, stereoscopic vision—when functioning as a pair. Something of that kind, she said, might represent the fundamental significance of sex. With this hypothesis, the family—i.e., the mated pair, with or without children

—was chosen at Peckham as the unit for observation of the inherent design in the growth and development of the social organism. The selected environment, for various reasons, could not be the homes or the workplaces, and so the field of leisure was taken, but leisure into which was introduced the greatest diversity of interest and activity, and which brought together people of all ages and of every type of culture and skill. A fairly good cross-section of a suburban community was obtained, and into the midst of this, without disturbance, the observer and his instruments were introduced. A system of periodic health overhauls and family consultations was inaugurated. It was not medical advice which was tendered at such consultations, it was simply a statement of the facts relating to the children and to the parents themselves which had been elicited during the overhau. During the four years of the experiment Dr. Pearse had not heard of one family who, within three months of the consultation, had not in some way acted rationally on what they had been told and had put it right. She described how the subject of pregnancy was approached, and an endeavour made to build up the woman's reserves. The result was that during pregnancy there developed among the Peckham Centre mothers an increase of maturity—a kind of "bloom"—which was quite outside any previous experience of her own in a long medical career. These mothers were in the swimming bath a fortnight before their confinement, they were engaged in the activities of the Centre three hours before they went to hospital, they led a more active life during their pregnancy than at any other time, and from the way in which they carried themselves the casual observer would never have noticed that they were pregnant. Dr. Pearse also described the way in which the "man friend" or "woman friend" of a member of the family was introduced into the Centre, and, as marriage was approached, the procedure of health overhaul and consultation extended to him or her also. The observers further looked for the integration and co-ordination of the families of the Centre with one another so as to form a living society in which all shared. Unhappily, war has interrupted this experiment as so many others.

A joint meeting of the Ulster Medical Society and the Northern Ireland Branch of the B.M.A. was held on Feb. 17 in the Whitha Medical Institute, Belfast, when Lieut.-Col. Ian Fraser spoke on penicillin on the war front. After giving the history of bacteriostatic drugs from 1850 to 1943 he outlined the progress of research on penicillin from Fleming's discovery in 1929. In recording the properties of the drug, he mentioned the trouble produced by it in laboratories, its bad effects on fruits, and its use in the manufacture of valuable by-products. There were 600 varieties of the genus *Penicillium*, the best-known being *glaucum*, *rubrum*, *patulinum*, and *notatum*. Different media were used in its production, the penicillin appearing as a felt on the surface of the medium. As it grew only on the surface, a large surface area was required to produce large quantities. The underlying fluid could be aspirated and replaced by fresh media. It was reduced to the form of a yellowish-brown powder. It was used as a calcium or sodium salt, and was destroyed by acids, alkalis, heavy metals, alcohol, oxidizing agents, heat, rectal contents, *B. coli*, and air organisms. It had no ill effects on white blood cells or fibroblasts. The mode of action was unknown. The most sensitive organism was the gonococcus. With small doses organisms could become resistant just as they did to the sulphonamides. Penicillin was used locally as a calcium salt or as a sodium salt parenterally. Col. Fraser then showed a film illustrating its use on the wounded of the Sicilian and Italian campaigns.

## Effects of Inanition and their Treatment

The Scottish Group of the Nutrition Society met recently in Glasgow to discuss science and post-war relief. Dr. H. E. MAGEE, of the Ministry of Health, in a paper on some effects of inanition and their treatment, pointed out that relief parties going to Europe would not be faced with a host of well-defined deficiency conditions to be corrected by appropriate nutrient concentrates and vitamins. A knowledge of the physiological effects of severe malnutrition would be needed, and in many cases care and discretion in the giving of food. Professional fasters who had survived for as long as 50 days on water only showed changes in body weight, B.M.R., temperature,

and blood volume. Animal experiments had shown that the alimentary canal itself was affected; the mucous membrane atrophied, its protective function decreased, toxins were absorbed more readily, while ulcers were apt to form in the large intestine. The people of Europe would be suffering from varying degrees of partial deprivation, anaemia, hunger oedema, and from neurological and gastrointestinal complications. The last was the most serious of all and in advanced cases recovery was rare. The gums were swollen and inflamed as in scurvy, the tongue red and denuded of epithelium, and the teeth decayed. The stomach was dilated and there was a profuse watery diarrhoea with as many as 30 stools a day. Blood protein fell to a very low level. Death was due to severe diarrhoea with cardiac failure. Mild cases responded rapidly to easily digested food, while cases which came between the two extremes required hospital attention with careful feeding and symptomatic treatment. Opium and potassium permanganate were useful for the diarrhoea. The diet should consist of small quantities of food six times a day—milk, gruels, lean meat, very little fat, with pepsin and hydrochloric acid. Intravenous injections of glucose at frequent intervals helped. Good results had been obtained in many serious cases with intravenous administration of protein hydrolysates. The solution consisted of an acid hydrolysate of casein, tryptophane, cystine or methionine and glucose in Ringer's solution. Up to 4,000 c.cm. of this was given 8 hours out of 24; this yielded 80 g. protein and 1,600 calories. The method was at present under further clinical trial.

Dr. Harriette Chick, of the Lister Institute for Preventive Medicine, who described the famine conditions in Vienna after the last war, thought that the problems would be rather different this time. There would be fewer cases of simple vitamin deficiency, but a great deal of general malnutrition.

## Correspondence

### Hygiene, Morale, and Desert Victory

SIR,—As Assistant Director of Hygiene, Eighth Army, during the relevant period I read Lieut.-Col. H. S. Gear's excellent article, "Hygiene Aspects of the El Alamein Victory," and your leading article thereon in the *B.M.J.*, of March 18 with the greatest interest and, with two exceptions in your leading article, with entire agreement.

The first exception taken is to the first sentence of your leading article, "The conditions that obtained in the Western Desert were so local and exceptional that much of the knowledge that can be distilled from the experiences of the Eighth Army therein cannot be applied directly in plans for military enterprises elsewhere." I submit that this is a disastrous viewpoint—a viewpoint that is unfortunately held too generally, with the consequence that many of the valuable lessons learned there are being overlooked. Warfare to-day is a matter of movement, rapid and over long distances, interspersed with long periods of inactivity while stores are being built up and short periods of pitched battles. Events on all fronts bear out this contention. The problems of administration and organization will be the same in any theatre of war. What hygiene or technical considerations that arose in the Western Desert will not arise in other theatres? The gross water shortage and to some extent the desert sore are the only conditions that are localized to that campaign. Every other problem will arise in some degree in other theatres of war, and no other is likely to be so easy to deal with hygienically and to be so generally healthy. What great need therefore is there for us not to forget those lessons we learnt, particularly those in connexion with organization, when fighting in other places where we may meet all the same difficulties plus many more?

Secondly, you say that the Army at El Alamein was "dispirited." They were physically exhausted and perhaps bitterly disappointed, but never dispirited. Dispirited men could never have fought as did those tired troops between the sea and the Qatara depression during the early part of July, 1942. The leadership of the commanders of those days, such as the late "Straffer" Gott and "Dan" Pienaar and many others who are still living, never allowed the troops to become dispirited, and the morale of the Eighth Army during July, 1942, was never higher.—I am, etc.,

R. LEANING,  
Lieut.-Col., R.A.M.C.

Army School of Hygiene, Mytchett.

### The Prisoner-of-War Mentality

SIR,—I was greatly interested in Major P. H. Newman's article (Jan. 1) and feel that he has done the prisoners a service. I hope that interest in the prisoners of war will be sustained throughout the post-war years, and that this time some sympathetic action will be taken. The cause of the prisoner will need the powerful advocacy of Press and people, and the *B.M.J.* could play a leading part.

Major Newman discusses the officer prisoner. The large majority of our prisoners are N.C.O.s and men, and the conditions will be sharply different from that experienced by officers. I feel that Major Newman is too optimistic about early recovery. I agree with Dr. B. R. Billings (Jan. 15) that the very large majority of our returned prisoners of war will be problems for their lifetime. The men on return will find the war over and be bewildered and hurt by public reaction and indifference. They should not be demobilized but offered a period of reasonable financial security. The alternative of attempting to assess disability and granting a pension will have to be considered.

The establishment of prisoner-of-war clubs is likely, in my opinion, to retard rehabilitation. The returned prisoner should be encouraged to mix with others who have not suffered similar experiences and to merge as soon as possible into normal service or civil society. I hope Major Newman will continue with his most excellent work, and trust that the question of the prisoner of war and his future care will be kept constantly in mind.—I am, etc.,

India,

JOHN HARKNESS.

### Health and Nutrition

SIR,—What's in a name? A name is a direction: a misnomer is a misdirection. Is "health centre" a misnomer? "Health" means whole (A.S. *heilō* = "health," from *hāl*, whole: M.E. *hole*). A mental deficient is not whole. A thyroid-short person is not whole. A malnourished child wants something and is not whole. Food of the needed quality is the major factor in building up a wholesome people. Patients only come to us for their defects and deficiencies to be recognized and remedied. "Thou canst make me whole" was the cry that met the Healer. (A.S. *hēlan*, to "make whole," = "to heal," is from the same word *hāl*, "whole.") The centre the White Paper sketches is a communal surgery, nothing more: a place for the work of healing.

But we are told our service is to be "directed towards the achievement of positive health" (Medical Planning Commission). That is to be our first and principal objective; and indeed it is the only aim of a true national health service. What means are we to use? The documents, White Paper and all, are silent. The means, however, will, upon reflection, be seen to be nine-tenths nutritional. To engender a people sound and complete in every attribute, with dynamic vigour, in very truth with positive health, the means is a sound nutrition, the yield of a fertile soil, the yield of the sea—which is always fertile—those, or the first at least, are prerequisites.

One paragraph in the White Paper (p. 8) states the problem with a candour which, in view of the complete failure of the document to attempt a solution, is astonishing.

"Much of present custom and habit still centres on the idea that the doctor and the hospital and the clinic are the means of mending ill-health rather than of increasing good health and the sense of well-being . . . the plain fact remains that there are many men, women and children who could be and ought to be enjoying sense of health and physical well-being which they do not in fact enjoy. . . . These deficiencies . . . a comprehensive service should seek to make good."

That is the paragraph.

The seeker (the comprehensive service of doctors, hospital and clinical facilities, all for remedial medicine) will never "make good these deficiencies." The service may provide a surgeon to remove a toxic goitre; but to prevent it is beyond the scope. The comprehensive medical services cannot wash the banks of estuaries with iodine-containing mud, they cannot carry inland seaweed by the 100 tons. A Nutrition Minister, Col. Llewellyn, perhaps, if he could engulf Mr. Willink and Mr. Hudson with the powers of Agriculture and Forestry, could make a real impression on the great nutrition problems.

Our people are grand material. A plentiful poor-quality dietary stultifies them. Aware that something is missing, they know not what, they may be discontent. Strikes often mean unrecognized dietary deficiencies. But the ethnic threads woven into the texture of our folk are of high quality. They were tested by invasion, by battle; and two or three thousand years have not weakened the germ plasma. What of the other factor? The cattle-breeder's jest, "Half the pedigree goes in at the mouth," speaks a true thing. The show-ring awards go to the well bred that are well fed. Our people are well bred. The germ plasma is all right. Not so their nutrition. A primary quality in feeding stuffs is freshness. "Alive or nearly alive" is the motto. Apply that to our tables and the gulf between what should be and what is appears. The industrial revolution has cast its blight on the farms; and the food which was used fresh in the old static days now in this age of transport in *excelsis* reaches us from afar, processed in factories or frozen in the Antipodes or autoclaved and tinned or fragmented in the mill, so that we get the shot of the food cartridge without the powder, treated in a thousand ways with skill and chemical mastery; but dead.

Yes, the title of the White Paper, "A National Health Service," is a misnomer and a misdirection. So is the expression "health centre." Healing, not health, is what they deal with. For that purpose we can claim that the doctor's work under the N.H.I. has, to a point, succeeded. To the "cure of sickness" the lowered death rate speaks. It is common ground that that medical work should be extended to the mothers and children. It is common ground that better access to the special departments of treatment is needed. I question whether the machinery of the White Paper and of Sir William Beveridge's report is necessary—except to safeguard the finance of the scheme, which seems the overt reason for the medical section of his proposals (Sect. 437 of Sir William Beveridge's report, last 3 lines). All-beneficent extension of the Act could have been made without this shattering disruption of our age-old profession. Extension is desirable, indeed necessary; but it will not create health. Positive health does not need doctoring: "They that are whole need not a physician"; it is nine-tenths a matter of nutrition, and to be engendered by the fresh product of sea and soil. When Health, Food, and Agriculture and Fisheries are bracketed, so as to minister to the nutrition of our people, we shall have a National Health Service worthy the name.—I am, etc.,

Holmes Chapel.

LIONEL JAS. PICTON.

### The Effects of Cold

SIR,—If you can spare me a little of your restricted space I should like to try to clear up a misunderstanding which I think I detect in Dr. Raymond Greene's letter of April 1 (p. 466).

I hope I have not stressed solidification as a necessary cause of immediate death of tissues when exposed to cold, for, as we all know, the skin can be solidified by the ethyl chloride spray for a very short period without necrosis ensuing. A slight prolongation of the exposure, however, produces subsequent sloughing. Yet individual cells *in vitro* always die when their cytoplasm is solidified, and so the evidence leads to a dilemma. It must be recognized, however, that a whole tissue in the body is composed of more than cytoplasm; there are, for instance, the tissue (intercellular) fluids, which may freeze without the cells themselves being solidified; in other tissues—e.g., bones, tendons, skin, etc.—the main mass is composed of material which is the product of cellular activity, the cells constituting but a small part of the total. This is particularly so in the case of the tails of such animals as rats and mice, which are often used experimentally. Solidification of a tissue, therefore, does not of necessity mean that the cytoplasm of the contained cells has been frozen: indeed the invariable display of supercooling in cytoplasm introduces a time factor which saves the cells in short exposures; hence the common experience with ethyl chloride.

Possibly the pathology of the cryopathies is best considered on a cellular rather than a tissue basis. In this sense I still think that there is a critical temperature (about  $-5^{\circ}\text{C}.$ ) below which immediate cellular death occurs, this being the basic

pathology of true frost-bite; while above this temperature the individual cells are very little affected and the subsequent changes (gaogrene, etc.) are secondary to reactive vascular and other phenomena, this being the essential pathology of trench foot, immersion foot, and similar conditions. Naturally in severe exposures both states will be present, since the temperature fall must vary, depending upon the depth of the tissue from the surface (temperature gradient); the clinical picture is thus rendered obscure by this superimposition of pathologies, and it is unwise to draw deductions therefrom.

The distinction between the two conditions is of much more than academic interest, for if the cells are destroyed during the exposure there is no hope of saving the part, whereas when the cells are alive there is hope that some treatment may be devised which will prevent their subsequent death from secondary causes.—I am, etc.,

London, W.1.

NORMAN C. LAKE.

### Epidemic Jaundice

SIR,—I have noticed for some considerable time reports in the *Journal* of an epidemic, or series of epidemics, of infectious jaundice which have appeared in various parts of England. It is of interest to me because for some months there has been an epidemic in my district in South-Western New South Wales. There may have been a wider distribution, but I cannot say with certainty.

I have noticed on one or two other occasions that we have had epidemics here, almost coincident with similar epidemics abroad, which cannot be explained merely on a basis of contact. I refer particularly to the 1937-9 epidemic of poliomyelitis: I believe that about then there were also epidemics in England, Germany, and the U.S.A. One is reminded of the theory that there is a periodic increase in the virulence of micro-organisms which is almost world-wide.

Clinically the cases are mild, both children and adults being affected. There appear to be a large number of cases which are so mild as to escape medical attention. The symptoms and onset are similar to those described in the *Journal*. I have been struck by the hunger which occurs as soon as the more acute symptoms pass off. So far as physical signs go, they are also similar to those reported but rather milder. Liver tenderness seems very common. The incubation period is hard to investigate, but one gets the impression that it varies from at least three weeks to a longer period. The epidemic has now been in progress since autumn last, or nearly a year.

This is a part of the State where medical practice embraces large farming areas. Sporadic cases are occurring in both small towns and farms remote from towns.

There have been no serious cases and no complications.—I am, etc.,

Ardlethan, New South Wales.

R. A. MCGREGOR.

### Toxic Effects of Sulphaguanidine

SIR,—In an article by Dr. H. G. Smith in the *Journal* of Feb. 26 the effects of sulphaguanidine on the skin are stressed, and in a letter published on March 11 Dr. J. H. S. Whyte draws attention to what he considers to be renal damage after treatment of dysentery with this drug. As neither skin rashes nor renal complications are commonly described by those who have had extensive experience of the drug in countries where dysentery is a serious problem, I feel it necessary to allay the fears of doctors who might be deterred from using sulphaguanidine in their occasional dysentery cases. It would be regrettable if patients were to be deprived of the use of a specific drug, or if the dosage were to be reduced below what is usually recommended—underdosage gives bad results.

In a hospital in the Middle East my colleagues and I had very considerable experience of this drug; we worked under conditions which would increase the risk of renal complications, and certainly would not diminish the effects on the skin. Yet "of the 323 cases treated with sulphaguanidine, often with very large doses up to 350 g., very few examples of toxicity have been found; the drug does not upset the patient any more than does kaolin: in four cases there have been rubelliform rashes about the tenth day, and there has been only one serious complication, a 'sulphaguanidine kidney,' which cleared up rapidly after the intravenous administration

of 2 pints of 4.285% sodium sulphate" (Bulmer, E., and Priest, W. M., *Lancet*, July 17, 1943, p. 69). The average dose was 100 g., and this was often greatly exceeded. I think an explanation must be sought for Dr. Smith's very high incidence of skin rashes (21 out of 44 patients); there may have been some variation in the sample of the drug he used, but he has certainly had an experience with which I am unfamiliar. Even if skin rashes were common, it is very doubtful whether they would matter.

Dr. Whyte's letter raises another hare: he suggests daily urinary examinations for crystals and red blood cells during treatment with this drug because he found them to be present in 14 out of 25 patients whom he treated with quite small doses—51 g. "Sulphaguanidine kidney," the only serious renal complication, is almost unknown, and mine was, so far as I know, the only one reported in the Middle East. Crystals may indeed be found in the urine, and sometimes acetylated compounds of sulphaguanidine will occur, but less frequently than with the other sulphonamide drugs; the presence of a few red blood cells is not unusual in the urines of healthy people.

May I, therefore, register my plea that sulphaguanidine be used in dysentery in full doses, without raising bogies about renal damage or skin rashes?—I am, etc.,

ERNEST BULMER,  
Brigadier.

### Cause of Silicosis

SIR,—Mr. Blacktin's letter in your issue of April 1 invites criticism, if only because the unsolved problem of the true cause of silicosis is so serious that misleading comment on it is to be deplored; and I fear that his remarks are of this kind.

When first considering the study of the action of dusts on weevils I had some hope that it might throw light on silicosis, partly because silica chanced to be practically the only "inert-dust" insecticide known at that time. The hard facts of experiment soon showed, however, that the two problems had little else in common. It is an accepted fact that in silicosis silica (in some form) is the causative agent. In contrast, any finely divided hard sharp substance can act as an insecticide, including calcined alumina, which is extensively used in the potteries as a safe substitute for silica. Further, dusts act on weevils by breaking down an invisible waxy waterproofing on the insect's shell (which, incidentally, is rigid and not subject to movement), causing abnormal water loss and eventual death by desiccation. Assuming that Mr. Blacktin has really read my *Cantor Lectures*, it is a little difficult to follow his reasoning, since there is in fact no shred of evidence that any connexion exists between the causation of silicosis and the action of insecticidal dusts.

Incidentally, I would remark that there is no real reason to suppose that a sharp particle will lacerate a soft surface on which it lies. The best lining in a ball-mill used for grinding hard material is rubber, because it is not abraded even under extreme conditions of movement under pressure.—I am, etc.,

Royal College of Science, London, S.W.7.

H. V. A. BRISCOE.

### Electrocution: Revival by Rocking

SIR,—This case will interest specially the many doctors who teach resuscitation to their first-aid classes.

A youth was electrocuted at his work, respiration ceased entirely, he was pulseless, livid, ears very blue. Div. Supt. F. Dowell promptly performed Schafer's method for 10 minutes without response. By that time Amb. Officer C. B. Cole and Sergt. W. S. Hill had extemporized for the stretcher a fulcrum of concrete blocks 3 feet high, on which Eve's rocking method was performed a dozen times a minute through an angle of 45 degrees each way. (This angle was verified and obtained with the handles conveniently a foot from the ground.) After 20 minutes of rocking, respiration was completely restored.

To save time the wrists and ankles were not bound to the stretcher handles. This was found unnecessary as it was an A.R.P. stretcher of which the wire mesh had bulged from use. The patient did not slip or need support. Blankets had been placed above and below, as in A.R.P. handbook No. 10.

Respiration again failed in the ambulance on the way to the hospital, but soon responded to Schafer's method, and recovery was complete.

Supt. Dowell has supplied me with the above careful details of this fine piece of first-aid work at Leicester recently. He adds:

"The rocking method certainly ventilated the lungs better than Schafer's method, and we are all convinced that rocking saved this youth's life. All the members of this Division have previously been rocked and agree that it makes you inhale and exhale better than Schafer's method."

This case also provides a complete answer to the criticism of Dr. Lloyd Davies's letter in the *Journal* of Jan. 29. He is a firm believer in the rocking method provided the patient is fastened by straps above the shoulders and under the perineum. But his electrocuted girl was so limp that he maintains she would—if fastened only by wrists and ankles to the stretcher-handles—have been shot off the canvas stretcher when tilted at 45 degrees, with peril of fractures of neck or limbs.

The method I prefer is to start Schafer's (or Silvester's) method at once on the ground (blanketed). The stretcher and trestle are brought to him there, he is rolled on to the stretcher and Schafer's method continued while the ankles and wrists are quickly bandaged to the handles. Then, without fumbling, the stretcher is placed on the trestle and rocking started by a full head-down tilt of 45 degrees. The feet-down tilt is not started until fluid from the lungs or stomach has ceased to flow. Rocking is continued at 10 double-rocks a minute—i.e., 4 seconds head down, 2 seconds feet down. Warmth is essential.—I am, etc.,

Holt.

F. C. EVE, M.D., F.R.C.P.

### Chronic Pulmonary Catarrh in Childhood

SIR,—Many readers of Dr. A. Bryan Taylor's thoughtful paper upon this subject (April 1, p. 453) will feel indebted to him for focusing their attention on an important and somewhat neglected problem in children's medicine. Repeated respiratory infection is common among children in ordinary practice, and, of course, very many examples are seen in an out-patient department. Some of these patients are "wheezy" in the attacks and may be sent up by their doctors because asthma is suspected. Infection certainly plays a large part in many cases of asthma, but all that wheezes is not asthma, and differentiation is no simple matter. Dr. Taylor would have us follow the example of Leys, who used the label "chronic pulmonary catarrh"; this surely is a term to be avoided, for, like "chronic bronchitis," it is by no means precise and apt to be loosely applied. Moreover, "chronic pulmonary catarrh" does not describe these cases really well, because they usually suffer from repeated respiratory infection, the brunt of which falls on the upper respiratory tract, seldom so much affecting the alveoli of the lung, except when the pneumococcus or some pneumonia-producing virus is responsible.

Certainly we should avoid any label tending to discourage the search for underlying causes. We need to elucidate the background of the so-called chronic bronchitis or pulmonary catarrh, so that treatment can be planned on a rational basis, and a broad consideration of the factors governing both infection and the patient's resistance is the only proper way of ascertaining the causes of these repeated respiratory attacks.

**Infection.**—The reason for the recurring infections may be discovered on entering the home. Perhaps the most elementary rules of ventilation are being ignored, or no harm seen in the presence of somebody with an acute respiratory infection in a room crowded with children. In a recent patient of mine the school-room was overcrowded and badly ventilated, so that the children were always getting colds.

**Resistance.**—When we turn to questions of resistance we are so in deep water through lack of accurate knowledge. Probably there is a group in which defective diet is important (too much carbohydrate or too little of protective foods). Age and constitutional or inherited factors, as well as hygienic ones such as fresh air and clothing, also play a part which is somewhat undetermined.

Experience shows that a large proportion of these patients have nasopharyngeal abnormalities: there are, for example, the children who are seldom free from nasal discharge from October to March, indicating recurrent or persistent sinusitis; and sometimes there is disease of the tonsils, or perhaps they or the adenoids have been

unskillfully removed, for this is one of the worst-performed operations in surgery.

As Dr. Taylor rightly says, allergic asthma as well as local disease in the lungs has to be excluded, and his emphasis on the need to remedy faulty breathing is also welcome, but his paper does not sufficiently emphasize that treatment depends on accurate diagnosis. It is true that a change of climate may check the sequence of repeated respiratory infections, but most of these children need to be helped without taking them from their homes, and we should first discover what is the matter with them. Clinical and social medicine should here co-operate in diagnosis and treatment, which implies team work between physician, radiologist, nose-and-throat surgeon, physiotherapist, and health visitor.—I am, etc.,

London, W.1.

REGINALD LIGHTWOOD.

SIR,—I have read this article by Dr. Brian Taylor (*Journal*, April 1, p. 453) with great interest, but would beg to disagree with some of his statements: first, that when "recurrent colds and upper respiratory catarrhs were followed by generalized pulmonary effects—coughing, tight chest, wheeziness, and more or less 'asthma'"—they have no true allergic basis; secondly, that "textbooks and the like do not appear to recognize this common and troublesome condition"; and, thirdly, that "skin-testing may show sensitivity to proteins, but these are usually so varied as to make the knowledge of little value."

In many discussions and writings on asthma in childhood (e.g., Garrod, Batten, Thursfield, and Paterson, *Diseases of Children*, 1934, 3rd edition) I have described this "lung damage type," classifying it as such in order to stress the role of upper and lower respiratory infections and the pulmonary complications of the infectious fevers in childhood in the precipitation of the initial wheezy attack, and the part of each subsequent infection in causing a recurrence of the cough, tightness, or wheeziness. A vicious circle seems to be present: the body appears to have very little resistance to even low-grade infections, and if the mucous membranes are constantly irritated by some air-borne allergen an oedematous state is maintained to produce a more fertile field for the growth of any roving bacteria. On the germs taking up their residence the catarrhal symptoms increase, the child is put to bed, propped up with ample pillows, kept in an under-ventilated and over-heated room, and its digestion overtaxed with milk, sops, and cereals. Obviously the difficult breathing that ensues is an allergic manifestation, and surely the knowledge of skin tests which showed a sensitivity to certain proteins—usually feathers, down, horsehair, dust, milk, or cereals—is now of great value in therapeutics. During the infection the body's general resistance is lowered, and the available protective adrenaline production is reduced or used up more quickly; contact with the irritant bedding is increased from 10 hours to 24 hours a day; the dust content of the room is increased by rendering ventilation inadequate in attempts to avoid draughts; the temperature of the room is increased so that the natural evaporation of moisture from the mucous membranes is impeded and their swelling and clogging augmented. In fact, the child is saturated to excess with various potent allergens when resistance is at its lowest ebb.

The deleterious effect of air-raised shelters on these children is the result of adrenaline exhaustion consequent on prolonged fear; greater liability to infection from chilling, overcrowding, and the lack of ventilation and the disinfectant action of any sun's rays; and the greater concentration of allergens—dusts, moulds, eiderdowns, pillows, rugs, and even animals in a very confined space.

Surely the tightness of the chest, cough, or wheeziness in such cases is just as much allergic in origin as the aggravation of an infantile eczema by administering egg-white or fish? If the usual irritants are avoided in these cases of "chronic pulmonary catarrh" constantly—the bedding freed from all feathers, down, horsehair, and dusty substances; the bedroom maintained with a minimum of ledges, curtains, carpets, or other dust-holding surfaces; and the forcing of large quantities of milk and cereal foods is forbidden, especially during infections—the agreed very beneficial effects of changes of climate, breathing exercises, and general hygiene can be greatly augmented and any neuropathic tendency discountenanced.

Dr. Taylor seems to suggest that the criteria of a true allergic asthma are the previous occurrence of infantile eczema, a direct relation between the attacks and foreign proteins, freedom from respiratory symptoms and signs between attacks, and a greater frequency of symptoms in the summer months. In my experience only one child asthmatic in three has had infantile eczema; as severe asthmatic attacks can be produced by aspirin as by any foreign protein; the majority of asthmatics have a blocked or runny nose even between attacks; and with the exception of pollen-sensitive cases most asthmatics are worse in the winter.

Finally, most of the cases described will respond to adrenaline if, first, it is adequately given—small doses being frequently repeated at short intervals and the injections continued for hours after the apparent lessening of the spasm—and, secondly, the sensitizing substances have also been thoroughly removed—the irritant bedding changed and over-alimentation avoided, however "valueless" the skin reactions may have appeared in the free interval.—I am, etc.,

London, W.1.

GEORGE BRAY.

### Pregnancy and Pulmonary Tuberculosis

SIR.—There appears to be something connected with the mysteries of childbirth in the tuberculous woman which, according to Dr. Logg (April 1, p. 468) and Dr. McDade (Jan. 15, p. 97), renders one particularly liable to censure by presenting conclusions which conflict with prevailing opinion. It appears that I have even gone so far as to formulate conclusions contrary to those reached by a B.M.A. conference which sat at Oxford in 1936. May I, through your columns, respectfully remind these gentlemen that we are members of a scientific profession, and deductions based on research should not be influenced by the opinion of others, however eminent the individual or august the gathering. The Black Notley cases have all been treated by myself, or under my supervision, and I maintain that, based on these, my conclusions are logical ones and are definitely not precluded by Dr. Logg's rather dogmatic statements, for which he produces no evidence other than expressions of opinion.

Dr. Logg states that my deductions are not supported by "latest work elsewhere," but he gives no references. I do not know of any comparable recent work, but Jameson at Saranac Lake Sanatorium (*Gynecological and Obstetrical Tuberculosis*, Montreal, 1935, p. 134) reported similar good results in 1935. I am not familiar with the facilities in London for the care of pregnant tuberculous women, but so far as I am aware Black Notley is the only sanatorium in this country which provides the special facilities described in my paper. In this respect at least Dr. Logg must grant London's inferiority to Essex. With reference to Dr. Logg's six "prominent facts," I would like to say:

1. While it is true that some tuberculous women date their illness from a confinement, the number of similar cases in which this cannot be shown must be vastly greater. (I have no figures—neither, apparently, has Dr. Logg.)

2. I have not claimed that pregnancy is likely to benefit the lungs of a tuberculous woman, but I am not alone in noting the improvement that does sometimes occur, and we must remember that many factors in the immunology of tuberculosis are still not yet understood. It may be that, as suggested by my colleague Dr. M. C. Wilkinson, the endocrinal changes which take place in pregnancy have an influence on tuberculosis.

3. Seventy out of 75 quiescent and arrested cases passing through pregnancy and labour without harm is more than a "proportion," and even Dr. Logg must admit this is a significant figure.

4. The usual length of stay after confinement at Black Notley is, for quiescent cases, 1 month under wartime conditions, but was previously 3 months. "Active" cases are retained as long as necessary for treatment. The number of the latter cases was admittedly small (25), but all were under careful observation for periods varying from 2 months to 3 years, and the fact that 18 of them were ultimately discharged either quiescent (8), improved (4), or unchanged (6), does not support Dr. Logg's assertion that "the large majority of active cases tend to deteriorate appreciably during pregnancy or within a few weeks of labour."

5. Combined obstetrical and tuberculosis treatment is precisely what is provided at Black Notley.

6. Reference to my paper (*Journal*, Dec. 18, 1943) will show that I agree with Dr. Logg in that therapeutic abortion is indicated in some cases, and possibly more frequently so when the facilities I

described are not available; but I had hoped that the article, incomplete though it was owing to space restrictions, would have at least suggested that many pregnancies in tuberculous women are unnecessarily terminated.

I feel that it is very seldom safe to be dogmatic in dealing with tuberculosis, and while presenting this letter to refute Dr. Logg's accusation of "precipitate deductions," venture to commend "cautious comment" to him in subjects where much research still remains to be done.—I am, etc.,

Brintree.

R. C. COHEN.

### Anaesthetics, Old and New

SIR,—Recent publications in the *Journal* tend to revive the impression that all is not yet well in the world of anaesthesia. May I, who have been a teacher of anaesthetics for over thirty years, be permitted to express my views on this subject.

Dr. Spoor (March 11, p. 374) writes: "The G.P. uses chloroform and will continue to use chloroform until something equally powerful, convenient, pleasant, and withal less toxic is discovered." I hope not, and I know that the many students I have taught will not. Dr. Spoor's letter has been ably answered by Dr. Dale (March 25, p. 434), but if Dr. Spoor would like to have further information as to why chloroform is condemned he might be interested to read "The Present Position of Chloroform" (*Lancet*, June 12, 1926). In 1925 it was agreed at a meeting of the Scottish Society of Anaesthetists that "in the light of our knowledge of the properties of chloroform, to proceed to induce full surgical anaesthesia supplied only with the means of administering chloroform is unjustifiable." To-day that opinion holds good.

Dr. Kemp, in his article on the aetiology and treatment of convulsions during anaesthesia (April 1, p. 447), suggests that a convulsion during anaesthesia is due to interference with cell respiration in the brain resulting from a condition of anoxaemia. So far, indeed, it is the only acceptable explanation of this phenomenon. Dr. Kemp, however, fails to explain (1) why there were no recorded cases before 1924, and (2) why cases occur with a certain frequency in the records of some administrators and not at all in those of others. These two facts definitely support the view that recent methods and manner of employing anaesthetics are important factors in causing convulsions.

Open ether is not a very recent method, and, as a matter of fact, is relatively rarely the method employed when ether convulsions occur. In a series of over 20,000 cases of open ether I have not seen a case of ether convulsions. Yet Dr. Kemp states that "prophylactic treatment consists in avoiding open and semi-open administration of ether." What meant by "semi-open" I do not know. Open ether, as I understand it, is a perhalation method with mask and drop-bottle and no limitation of atmospheric air. His first case of convulsions (Case 1, 1924) is reported as occurring during 'anaesthesia with ether vapour, with oxygen and semi-open technique with mask and damp towels.' I could well believe that damp towels, suitably employed, could be depended upon to bring about a condition of anoxaemia and convulsions. His Case 4 (1943) is typical of the complications and risks associated with modern methods: "pentothal-intratracheal nitrous oxide-ether . . . closed filter circuit . . . patient in second plane of third stage of anaesthesia . . . pulse 110, colour dusky." All this for a skin-graft operation requiring a simple gas-oxygen administration, and perfectly illustrating the manner in which the misuse of the modern machine leads to anoxaemia and convulsions.

What exactly is the value to the patient of the technique adopted in the above case? It is a method, too, which corresponds to that employed in many other places—e.g., cranial nerve palsies following general anaesthesia (see Humphrey and McClelland, and Carden, March 4, pp. 315 and 319). Dr. Carden refers to the closed-circuit carbon dioxide absorption technique as being almost a routine practice of most anaesthetists, its outstanding advantage being that a quiet operation field is ensured by the diminished respiratory excursions. This is certainly an indirect advantage to the patient, for the surgeon is able to operate more swiftly and with less trauma. I am not aware of any other advantages to the patient, and have not infrequently observed profuse sweating and con-

sequent dehydration. I look upon the closed circuit as an unfortunate necessity when cyclopropane is indicated as the anaesthetic agent to be employed. One must not forget, too, that surgical shock is associated with a low blood pressure due to a falling-off of the cardiac output. The cardiac output depends upon the venous return, and the venous return is greatly assisted by the respiratory excursions. Sufficiently quiet respirations can be assured by appropriate premedication.

It is very difficult to assess the value to the patient of any particular anaesthetic technique, so much must depend upon the skill and experience of the administrator. A method which saves time and trouble, entertains the administrator, and satisfies the surgeon, may not be the best for the immediate and post-operative welfare of the patient.—I am, etc.,

Dundee.

ARTHUR MILLS.

### Medical Research

SIR,—May I add my voice to that of Mr. Malcolm Donaldson, who in the *Journal* of April 8 makes a plea for medical research as a career, and clamours for better conditions and some encouragement for those who show aptitude and interest and a bent for research work.

Various agencies have been set up in the course of time for the cultivation or encouragement of medical research—academies under Government patronage, learned and professional societies formed by interested individuals, special endowment funds the trustees of which distribute income in the form of subventions, and, finally, research professorships occupied by individuals who enjoy the advantages of university associations while freed from ordinary university routine. The final phase in the development of research was the outright institute for medical research established for the express purpose of expediting the increase of knowledge in the field of medicine.

In the past, as Mr. Donaldson points out, recently qualified men with a bent for research too often had to give up hope of developing it for lack of means of support during an apprenticeship. Later came the epoch when grants were obtainable from various sources, but their acceptance usually implied some obligation to collect observations or experimental results for publication. It is now realized that the time spent on immature effort of this kind can be better applied, and that allowance for an unproductive period may yield far better fruit in the long run.

With this view in mind the Government in 1920 set up under the jurisdiction of the Privy Council the Medical Research Council, through which young research workers are maintained in various laboratories and clinics throughout the United Kingdom. In most places where active investigation is going on the beneficent and intelligent co-operation of the Medical Research Council may be discovered. In addition to its distribution of subventions to research workers in universities, hospitals, and kindred institutions throughout Great Britain, the Council with part of its modest funds runs the National Institute for Medical Research at Hampstead. There are very few medical men who are familiar with the manifold activities of the M.R.C. or with the mechanism and general principles guiding its actions. These are set out at some length in the *Lancet* (Aug. 6, 1938), and anybody interested in medical research should make a point of becoming familiar with the workings of the M.R.C.

The financial side of medical research, however, is unsatisfactory. The annual grant from the State Treasury to the M.R.C. is now £215,000. In addition to its public funds, the Council are in a position to help directly or indirectly by advice in the disposal of private endowments for medical research. These they receive from various sources. At present the State provides but meagre financial support for medical research, and though the country is still conservatively inclined, British medicine is moving towards the larger conception of scientific medicine. Now is the time for the profession to organize and clamour for more money with which to conduct research work. A mere £215,000 is, of course, inadequate, and the Government can afford a much larger sum.—I am, etc.,

G. R. W. N. LUNTZ.

It should be added that it was in 1920 that the Medical Research Council received its present title and constitution. The move to provide public money for research was made in

1911, in Mr. Lloyd George's National Health Insurance Scheme. It was in 1913 that the Medical Research Committee (continued in 1920 as the M.R. Council) was established to administer the funds for medical research provided under the National Health Insurance Act.—Ed. *B.M.J.*

### Babies in Glass Cages

SIR,—I was careful in my previous letter not to express a personal opinion regarding the use of glass cubicles, and merely recorded what I had been told in Vienna, where the idea originated. This was that the idea had been abandoned because it gave poor results owing to the children being lonely. It appears that Dr. Baar wants my opinion, so he shall have it. First, he states that the use of cubicles had been abandoned in Vienna because von Pirquet was dead. Surely this is a fantastic point of view. Has insulin been abandoned since Banting's death? Has the use of the arsenicals been given up since Ehrlich died? If ideas are good they do not die with their originator. Again, he states that "the majority of patients in babies' wards are not yet at a sociable age." My dictionary states that "sociable" means "disposed to associate with others." Are not babies disposed to associate with their mothers and others? Do not young mammals crowd together or press close to their mothers? This is so universal that it might be considered instinctual. Separation must be intolerable to a child—more so than to the adult. It might be said with truth that never again will the child be so sociable as it is in its babyhood. To place it in solitary confinement in a glass cubicle seems contrary to its instinctual reactions and is likely to produce harmful results.—I am, etc.,

London, W.I.

CLIFFORD ALLEN.

### Medical Boarding for the Merchant Navy

SIR,—I have read with complete agreement and much satisfaction the letters on the above subject by Dr. H. M. Royds Jones (Dec. 25, 1943, p. 831) and Dr. E. L. Caldwell Smith (Jan. 15, p. 96).

My own experience of the Merchant Navy is of a mere three years' duration, but in that short time I have found that one rapidly gets to know the more permanent members of one's crew, and even though some are not all their departures from positive health are known and can be dealt with. Such men constitute no problem; but every new man may have a chronic duodenal ulcer or a progressive suppurative otitis media—to quote but two types of recent headache—and in existing circumstances, when a busy "signing-on" day permits of only cursory examination, the condition can and will be discovered only when the sufferer reports sick—after sailing.

Until I read Dr. Caldwell Smith's letter I was not aware that the "Pool" kept medical records of any sort, but in view of this fact I think that the procedure which I have recently adopted in dealing with the genuinely sick men may recommend itself to Dr. Royds Jones and many other ship surgeons who find themselves faced with the same problem.

My procedure is to notify the Pool medical officer by personal letter at the end of each voyage of the names and ratings of all men who in my opinion are unfit for sea—e.g., epileptics, peptic ulcers, etc.—and at the same time to refer them to their own doctors, telling the men of all the steps taken. In this way a man cannot complain of high-handed treatment by the ship surgeon, as he comes into the care of his own doctor; or, if he has no doctor, he can be referred directly to the hospital of his choice for investigation and treatment. Thus, in theory at least, the Pool knows the men who should not be permitted to sign on again without careful overhaul, and as a central organization should be able positively to prevent known unfit cases from going to sea. This scheme will not prevent unfit men getting to sea once, but should prevent recurrences. Without prejudice, I must add that I have never yet received any acknowledgment of my communications from the Pool; so whether they are at all appreciated I do not know.

One man referred in the above way some six months ago recently rejoined my ship a much fitter specimen altogether—he was clinically a duodenal ulcer—and he tells me that

he spent three weeks in hospital, but in confirmation or negation of my diagnosis I have had no word. I am prompted, therefore, to the following plea: that the same procedure be adopted in dealing with ship surgeons' as with G.P.s' cases, and a note of the diagnosis and treatment sent by the hospital or doctor concerned. As such patients may apply for a position in the ship at a later date the information is of great importance. I do not imply that such notes are never sent, but their absence is a noticeable feature. A record card which should accompany each man from ship to ship is a necessity, but in the meantime the suggestions made above may be of some help.

So much for ships carrying a surgeon. But what about the greater number that sail without? Would it be possible for the Pool to supply a questionnaire as to the health of the crew, which would be filled in at the end of each voyage by the surgeon if carried, or by the chief officer (the cargo-ship "surgeon") if not, in which leading questions as to men with symptoms of the commoner incapacitating complaints would provide answers whereby the "Pool" medical officer could investigate more thoroughly any suspicious cases?—I am, etc.,

A. E. K. SALVI,  
Ship Surgeon

### Pavlov's Theories

SIR,—May I comment upon your two recent leading articles dealing with Pavlovian physiology and neurosis—namely, "Pavlovian Physiology and War Neurosis" (*Journal*, Aug. 14, 1943, p. 205) and "Behaviour and Neurosis" (Oct. 16, 1943, p. 487). These articles make the criticism that Pavlov's concepts of cortical function and their application to the problems of human behaviour and neurosis are vitiated by his failure to "think in terms of the meaning of stimuli," in "psychological" as well as "physiological" terms, and describes this failure as unscientific and biased.

If brain be the physical organ of mind, then either psychological and physiological phenomena are related precisely and interdependently or their relationship is non-existent, doubtful, or variable. Physiological experiment and deduction in the first case need take no special separate cognizance of the parallel phenomena of consciousness. In the second place, confusion of psychological concepts, definitions, and phenomena must surely be rigidly avoided. It would seem that it is the attitude of your leading article, and not that adopted by Pavlov which is "hardly in the spirit of science."

The statement that Pavlov refused to admit that the behaviour of experimental animals might be determined largely by physiological needs, aversions, conflicts, or other internal motivations is most misleading. He specifically noted that intrusion of strangers, hunger, satiety, desire for micturition, fear, neurosis, confinement, and external distraction profoundly modified his results, and not the least admirable feature of his work is the technique introduced to cope with these complications. Masserman's experiments are apparently made under less rigid conditions in which "the animal is not placed in complete isolation and isolated from every stimulus but the experimental one." The inference drawn that his experiments and conclusions are therefore more scientifically valid is difficult to follow.

It is stated in reference to the application of Pavlovian principles to social phenomena that "this may be good physiology but as a contribution to the all-round understanding of life this kind of wild analogy is a step backward into the materialistic abyss." If it is good physiology honest men must take that step; if not, then disproof will be on scientific grounds and not upon threats of an abyss or criticism of Pavlov's philosophy of life. Surely at this stage of scientific thought the fear that spiritual or psychological realities may be destroyed by demonstration of physical and chemical mechanisms for vital phenomena can be dismissed as mere vulgar error. One may deny in Pavlov's work the accuracy of his experiments, his scientific probity, the correctness of his generalizations, or their applicability to human affairs. One should, however, demonstrate grounds for so doing. To state that his speculations as to the cortical processes of Christian martyrs reach "the zenith of absurdity" without demonstration of the absurdity of fact or logic involved is simply to

darken wisdom. Scientific criticism must be divorced from confusion of terms, from preconceived dogma, and from emotion. Otherwise it can only mislead, misinform, and delay.

"Love," it is stated, "is more than an appetite, and war neurosis more than a stimulation of the fear reflex." One must assume, then, that either they are voluntary psychological acts or that they are independent of physical, neurological, and hormonal mechanisms. Otherwise it is difficult to see how they are to be distinguished from reflexes except in terms of complexity.—I am, etc.,

Brisbane, Queensland.

HAROLD R. LOVE.

### Shock Treatment of Mental Disorder

SIR,—I think the answer to the editorial question appended to my letter (April 15, p. 537) might be put thus: The psychiatrist does not provide "material cells, tissues, or secretions" with "a sane outlook." But so long as these are sufficiently capable of transmitting to the sufferer's mind the explanations and advice of the psychiatrist the sufferer may be able to appreciate and to some extent overcome the handicap of such of his material cells, tissues, or secretions as are not, for some as yet undiscovered reason, functioning normally. If his material cells, tissues, or secretions are in such a condition that they cannot transmit these explanations and advice, or enable the sufferer's mind to interpret them, the mind remains, of course, inaccessible, but not necessarily—or at any rate probably—in itself diseased.—I am, etc.,

London, E.C.1.

H. H. BASHFORD.

### Service Medicine

SIR,—We feel that the anonymous letter published in your issue of April 1, under the heading of "Service Medicine?" demands a reply, if only to correct the statement that it "so accurately" expresses the views of many serving members of our profession. As members of the staff of two teaching hospitals who have been in one of the Services since the outbreak of the war we feel that we have had exceptional opportunities of seeing "Service medicine" and of comparing it with the conditions of pre-war civilian practice, both hospital and private.

Experience over nearly five years has convinced us that Service patients, whether officers or other ranks, get better medical attention as regards diagnosis, treatment, rehabilitation, and after-care, than do civilians, even in peacetime. Those who, like ourselves, have been in consulting practice are all-too-familiar with the carcinoma of the rectum treated with kaolin for months, or the advanced case of phthisis missed through failure to examine the sputum or x-ray the chest. This type of catastrophe very rarely occurs in the Services.

It is of course true that in the Services fuller and more accurate clinical notes are kept, and that administrative arrangements are such that a full medical history is available whenever a Service patient falls ill. Such a system is essential not only from the point of view of continuity of treatment but safeguards the interests of the patient in connexion with the attributability of his illness and subsequent pension, both of which may depend on accurate records; these incidentally will be of great value at a later date from the point of view of medical statistics and their bearing on public health. In our experience the primary factor which overrides all others is what is best for the individual patient.

As regards equipment, that in the Service hospitals we have visited is as good as in the teaching hospitals and better than in the majority of the voluntary hospitals. No piece of equipment asked for and needed for the good of the patients is refused if justifiable and available. When special treatment, such as deep x-ray, is required for which no Service facilities are available the patient is promptly transferred to an Emergency Medical Service bed where the required services are available. Even in sick quarters the equipment and the supply of drugs are better than most practitioners are likely to carry in their consulting rooms.

Your correspondent complains that he has not enough work to occupy his time. Obviously in any Service in wartime circumstances over which the medical authorities have no control may temporarily increase or diminish the stress of work. It has, however, been our experience that in the rare cases

in which we have heard this complaint from medical officers the officer is either lazy and incompetent or else he is one of those disgruntled persons who is primarily interested in his own comfort and career rather than in his contribution to the war effort. If there is to be a State Medical Service it can only be hoped that your correspondent will see his way to remain out of it.—We are, etc.,

London, W.1.

STANFORD CADE,  
J. J. CONYBEARE.

## Obituary

J. C. DUNLOP, M.D., F.R.C.P.Ed.

We regret to announce that Dr. James Craufurd Dunlop, formerly Registrar-General for Scotland, died at Drumbug, North Berwick, on April 10.

Born on Sept. 3, 1865, the son of a Glasgow merchant, he was educated at Christ's Hospital and the University of Edinburgh, graduating M.B., C.M. in 1887 and proceeding M.D. in 1895; he also took the M.R.C.P.Ed. and M.R.C.S.Eng. diplomas, and was elected a Fellow of the Royal College of Physicians of Edinburgh in 1891, afterwards serving as vice-president. Dr. Dunlop went to Strasburg, Vienna, and Paris for postgraduate study; on his return to Edinburgh he served for five years as an extra physician to the Royal Hospital for Sick Children, and was then appointed medical superintendent of statistics at the Registrar-General's office. In 1914 he went temporarily to the War Office in London as Director of Statistics in the Department of the Surveyor-General of Supply. In 1921 he became Registrar-General for Scotland and was responsible for the Census of that year; he retired from the post in 1931 on reaching the age limit.

James Dunlop was a statistician of international repute; the Faculty of Actuaries of Scotland made him an Honorary Fellow and he was a member of the International Statistical Institute. Unofficially he was responsible for the only two life tables compiled for Scotland—one based on the 1911 Census and the other on the 1921 Census. Among other public services he worked as a member of the Royal Commission on the Care and Control of the Feeble-minded. He had been inspector under the Inebriate (Scotland) Acts, and assisted for some years the medical adviser to the Scottish Prison Commissioners. A keen sportsman and lover of open-air pursuits, he took particular pride in his appointment as a member of the King's Bodyguard for Scotland (the Royal Company of Archers).

R. J. COULTER, F.R.C.S.I., D.O.

We announce with regret the death on Easter Sunday at the Royal Gwent Hospital, Newport, Mon., of Mr. Robert James Coulter, consulting ophthalmic surgeon to that and other hospitals and formerly honorary treasurer of the Oxford Ophthalmological Congress.

He studied medicine at Trinity College, Dublin, graduating B.A. in 1891, M.B., B.Ch., B.A.O. in the following year, and M.A. in 1907; he obtained the F.R.C.S.I. in 1899 and the Oxford Diploma in Ophthalmology in 1911. His first appointments were as house-surgeon at the National Eye and Ear Infirmary, Dublin, and at the Bristol Eye Hospital, and thence forward he devoted himself to ophthalmology, working in South Wales and Monmouthshire on the visiting staff of the Royal Gwent Hospital, the Newport and Pontypool Hospital, the Blaina Hospital, the Woolaston House Infirmary, and the Abertillery and Ebbw Vale Hospitals. He was a member of the Ophthalmological Society of the United Kingdom and of the Société Française d'Ophthalmologie; and among other writings on his specialty he contributed the section on injuries to the eye to W. J. Greer's *Industrial Diseases and Accidents*.

Mr. Coulter had a long record of service in the British Medical Association, which he joined in 1894. He was active in the local work of the Monmouth Division, president of the South Wales and Monmouthshire Branch in 1925-6, and a treasurer from 1933. At headquarters in London he was a member of the Ophthalmic Committee from 1923. At the Annual Meeting of the Association in Birmingham in 1911

he was secretary of the Section of Ophthalmology, and he held office again as vice-president of that section at Bradford in 1924 and at the Edinburgh Meeting in 1928, the year in which he gave the Montgomery Lecture.

#### SIR HENRY MAUDSLEY

Sir THOMAS DUNHILL, who was house-physician to the late Sir Henry Maudsley at the Royal Melbourne Hospital in 1904, sends the following appreciation:

Maudsley was the first to begin the teaching of modern neurology at the Royal Melbourne Hospital. That does not imply any dearth of good—or great—clinical teachers before him, but it is no criticism of those men to say that a patient with disease of the central nervous system received less attention than the condition merited. In the days when those teachers had graduated travel to the home country was not so usual as it became later, and neurology was comparatively young. Maudsley had grown up under the influence of his uncle and namesake who founded the Maudsley Hospital for mental diseases; he had the inquiring mind and he was student and house-physician with Victor Horsley, who for many years to come was working out the centres and tracts of the central nervous system. Maudsley was appointed to the teaching staff of the Royal Melbourne Hospital in 1904; before then he had been, for some years, on the staff of the Alfred Hospital, at that time not a teaching hospital. To him every neurological case was a fascinating problem, a spiritual adventure. One recalls his excited face, the tenseness in his well-groomed erect figure as he approached the patient; his "Now, now, now?" to one and another of his students as he unravelled the symptoms in his orderly way, correlating their knowledge of anatomy and physiology with the clinical picture. We saw the essentials shaping themselves in his mind. We learnt to see, to think, and to integrate as the signs were elicited and the picture built up—all this was new to us, and marked not a renaissance but the birth of neurology in Melbourne. A year or two afterwards the late Richard Stawell, who had been physician to the children's hospital, was appointed to the out-patient department of the Royal Melbourne Hospital. There is no subsequent graduate of this hospital who is not deeply indebted to these two men; each adopted the Socratic method of teaching, and together they started the second era of medicine in Melbourne. After them, succeeding generations of physicians and surgeons have played their part in advances in this department of medicine.

Maudsley was equally able in other branches of medicine. Specialization had not at that time reached the stage it holds to-day. Nor must his personal and human side be passed without some comment. Whenever something new appeared in the medical journals that gave promise of being an important advance, he would seek out a young graduate and say, "You are young, you have the time, you must work this out in the University laboratories, and see if it is true, and if it is of value."

Mr. ARTHUR DOUGLAS COWBURN, M.R.C.S., formerly coroner for South London, who died on March 27, was born at Queensferry in November, 1869, son of Capt. Arthur Cowburn, R.N. From Charterhouse he went to study medicine at St. Thomas's Hospital and qualified in 1897. After being called to the Bar in 1903 and taking the D.P.H., he was for a number of years M.O.H. to the Inner and Middle Temples. In 1912 he became deputy coroner for the Western and several other districts of London. He served in the R.N.V.R. during the last war, mainly at sea, and reached the rank of surgeon captain; after demobilization he became deputy coroner for the North-East London district and in 1924 coroner for the Southern district, from which post he retired in 1939. Cowburn held office as secretary of the Section of State Medicine and Industrial Diseases at the Birmingham Meeting of the B.M.A. in 1911; in 1935 he was elected president of the Coroners' Society; he had also been a member of the council of the Medico-Legal Society for a long period. When he took up his duties as coroner in South-West London he organized in co-operation with King's College Hospital a panel of pathologists to make post-mortem examinations, and he was instrumental in reforming the mortuaries within his district. His kindly consideration for the bereaved was much appreciated by all who attended inquests held by him.

The death of Dr. PERCY JAKINS at the age of 58 has left an honoured memory in the minds of those who can recall him as a member of the active staff of the Royal National Throat, Nose & Ear Hospital, and especially in the minds of those of his surviving colleagues at that hospital, which he served so well and with such complete unselfishness for over 30 years. Jakins came on the staff in 1885 and retired at the age limit shortly after the outbreak of the last war. He remained at his post during the difficult war years until 1918.

His help during that time was invaluable. He was a man of kind and genial temper, simple in manner, and easy of approach. He was very human, and his lively sense of humour endeared him to all with whom he came into contact, whatever their rank in life. He took a particularly close interest in the welfare of the nursing and other staff of the hospital, and they all had a warm affection for him. In his professional work Jakins was of a sound sense and excellent judgment. Trained as a physician, he had, in the main, the physician's outlook, but became a deft, confident, and successful operator, especially in the surgery of the temporal bone. He never attempted too much. He knew what he could not do, but he knew with equal clearness what he *could* do, and that he did right well. Little influenced by new theory or by the bright promise of novel ideas, his eyes, in the field of surgery, were not out upon the horizon, but committed to here and now. For him was no "brave music of a distant drum." His patients were sincerely attached to him, and for a man to be held in such affectionate regard by such large numbers is no mean tribute; this tribute Jakins indeed had in overflowing measure. With him passes one of the pioneers of otology and laryngology and one of those early workers who helped to found the name and repute of the Royal National Throat, Nose & Ear Hospital.—A. R.

Dr. NORMAN MACNAIR died on April 5 after a long and painful illness, borne with much fortitude and courage. He had a serious heart attack about seven years ago, followed soon after by a cerebral embolism, which curtailed his mental activities and made him almost totally bed-ridden. Dr. Macnair was educated at the Glasgow Academy and the University of Glasgow, afterwards continuing his education as a postgraduate in Vienna. He was a distinguished student, and at an early age obtained many degrees and diplomas, which were to assist him in his work as a practitioner in the West End of Glasgow. He took the B.Sc. of Glasgow University in 1894, M.B., C.M. (with commendation) 1897, M.D. 1899, M.R.C.S., L.R.C.P. London 1897, F.R.F.P.S.G. in 1902. He was house-physician, and afterwards assistant physician, in the Royal Infirmary, where he was closely associated with his teacher Dr. George S. Middleton, for whom he had the greatest respect. He was for a time assistant surgeon to the Glasgow Ear Hospital, where he learned much that proved of great value to him in his practice. He was also house-physician and assistant physician to the Royal Hospital for Sick Children—a position which he almost cherished most, as it brought him in contact with children, to whom he was devoted. With all this experience and preparation, it was not surprising that when he started in general practice he very soon had a large number of patients. As his practice grew, he became associated with the late Dr. Berkeley Robertson, who died a few years ago. His success, however, depended greatly on the man himself. He had a retiring and gentle disposition, and was at his best with his patients and with his medical friends. He avoided publicity, and took little part in public affairs and medical politics. In his earlier years he was a keen golfer and played a good game, but in his latter years, owing to ill-health, he interested himself in gardening. He built a small bungalow on the top of a hill among the green-topped hills of Lanarkshire, and for many years spent almost every week-end in his delightful home, with a garden full of alpine plants and heather. For the last few years after his enforced retirement he has lived there completely, enjoying as much as possible the secrets of Nature. He was fond of music, playing the violin at one time, but mostly devoting himself to singing. He had a beautiful clear soft tenor voice that gave great pleasure to his many friends at home and at medical dinners. He was a gentleman to the backbone, and his loss will be greatly deplored by all who knew him. Our sincere sympathy goes out to his wife, who helped to nurse him during these last seven trying years.—J. S. McK.

Dr. JAMES ROBERT NICOLL died on Oct. 24, 1943, at his residence, Toowoomba, Queensland, at the age of 85. He was born at Rhynie, Aberdeenshire, where the Nicoll Hospital has been erected in memory of his parents, the Rev. Alexander and Mrs. Nicoll. He was educated at Rhynie and Aberdeen Grammar School and graduated M.A. in 1878, M.B., Ch.M. in 1882 at the University of Aberdeen. In the following year he went to Queensland, where he held posts as health inspector at Brisbane and Mackay and as assistant medical superintendent at Goodua Mental Hospital, and in 1897 became medical superintendent at the Willowburn Mental Hospital. His work there during 30 years became well and favourably known throughout Queensland. Retiring at the age of 70 he lived at Southport, Brisbane, and later at Toowoomba. He was a generous supporter of all good causes and was held in high esteem. A tribute from a colleague of many years said of him: "Dr. Nicoll will long be remembered with affection by all those who knew him." Inquiries and expressions of sympathy were many,

during his illness, from old hands at Willowburn, both staff and patients. His long years of faithful and humane service endeared him to all who came in contact with him. One envied many of his qualities, his unflinching kindness, equable temper, remarkable memory and all-seeing eye, a physician, a scholar, and a gentleman! Truly one of the "old school."

Dr. W. E. Rutledge writes: It is many years ago that a suggestion was made to the Rev. SAMUEL HANNA that, being interested in theology and medicine, a medical degree was the only solution of his desire to understand more of the workings of the body as well as the soul. I was a medical student then, and made this suggestion. A few weeks later this idea was taken up, and thenceforth the then Presbyterian minister was on his way not only to get new ideas for his sermons but to becoming what he desired above all, a greater influence for good in the world, by being able to work in a dual capacity. After qualifying at Queen's University, Belfast, Hanna practised medicine in his spare time, and continued his work in the Church. Indeed, for a long time there were few churches in the city that could boast of the overflow of congregations eager to hear one of such outstanding personality, who was practising as a doctor and spiritual adviser at the same time. This man of strong opinions and kindness of heart, whom I have known as a personal friend for many years, must have surely been unique in the medical world. One interesting incident in his postgraduate career is worth reporting. While doing a locum for a country doctor, one of his patients died. At the request of the local clergyman he took part in the service at the graveside. Those present at the funeral looked in amazement at a doctor so joining in the service.

## Universities and Colleges

### UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated:

M.D.—J. Benn.  
FINAL M.B., Ch.B.—Part II: F. E. Aaron, V. Altman, W. Boyes, Joan S. Brierley, Joyce M. F. Briggs, G. H. Briggs, J. L. Capper, Barbara E. Clapham, H. F. Claye, H. H. Collins, S. Cope, Betty Craig, T. Debnay, J. Exley, G. W. Knight, E. Lyons, R. H. Merrick, Margaret D. Oakley, W. H. Oesterlein, D. E. H. Robertson, N. V. Sapler, Sheila F. Schofield, R. H. Seville, P. M. Smith-Moorhouse, G. A. Stanton, S. B. Tomlinson, E. Wolffenstein, C. J. E. Wright.

### UNIVERSITY OF WALES

#### WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates have satisfied the examiners at the examination indicated:

M.B., B.Ch.—Medicine: I. F. Barwell-Clarke, E. R. Edmunds, A. J. Evans, A. D. Evans, Marguerite J. Hennelly, J. C. Hughes, D. C. W. Jenkins, \*D. I. Jenkins, C. R. Jones, C. C. Lewis, D. A. Macfarlane, Mary W. Owen, Winifred S. Phillips, I. Rees-Mathews, F. W. Richards, E. G. Roberts, T. H. L. Rosser, L. P. Thomas. Pathology and Bacteriology: D. Anthony, W. H. Beasley, B. L. Crystal, L. G. G. Davies, J. H. Edworthy, E. M. L. Evans, Hannah P. Evans, L. A. J. Evans, Myrddin Evans, Joan Guy, J. C. Ham, B. E. Heard, I. D. Jacobs, P. G. Jagger, Jane W. James, W. J. Jenkins, J. G. Jones, D. O. Lewis, D. R. Lewis, W. T. Lloyd, Joy A. Macgregor, \*Gara D. S. Marshall, Isobel F. A. Mitchell, Margaret Owen, D. B. Price, \*A. Reed, E. G. Rees, R. M. E. Seal, D. R. Thomas, D. V. Thomas, \*M. S. Thomas, D. Tooms, L. L. R. White, Cairn M. Williams, D. M. Williams, P. R. J. Williams. Surgery: Joan Collins, D. M. Davies, S. W. V. Davies, T. K. Davies, Eileen J. Evans, H. J. Fisher, J. C. Hughes, R. G. Hughes, D. I. Jenkins, H. O. Jones, Alice M. A. Lee, D. A. Macfarlane, Eury Morgan, Isabella M. Pinkerton, G. D. Powell, D. B. Richards, P. W. Richards, W. Stevenson, Gertrude G. Thomas, L. P. Thomas, Vivien V. Tracey, Mary L. Williams.

\* With distinction.

### UNIVERSITY OF ST. ANDREWS

The following medical degrees were conferred at a graduation ceremony on April 6:

M.D.—Sheila T. E. Callender (with honours for thesis and University Gold Medal). J. Sims.

Ch.M.—H. A. Haxton.

M.B., Ch.B.—Minnie K. Herring, \*L. Frain-Bell, \*S. Bayne, \*H. B. Goodall, \*N. K. Smith, \*Margaret B. Noble, \*J. E. Hilton, \*J. M. Johnstone, \*R. M. Milne, \*Janet E. Beattie, J. M. Anderson, Eilice A. Baird, Jeanne M. Bower, D. M. Caird, J. C. Campbell, Margaret A. Curr, C. Fleming, M. Fletcher, H. G. Ford, J. C. Forfar, I. M. Grant, T. P. Grant, Dorothy A. J. Hamilton, Beryl R. Law, T. R. Macdonald, J. L. Mackenzie, W. J. McLaren, K. Milne, J. T. Paton, Margaret S. Purvis, Patricia J. S. Robertson, Winifred M. Ross, E. H. Russell, A. M. Stalker, J. Stohner, M. D. Thomson, T. P. Venning, A. G. Watson, H. E. R. Wem, Elizabeth R. Younger.

Prizes were awarded as follows:

Low Memorial Prize for the Most Distinguished Graduate: Minnie K. Herring.  
Royde's Memorial Prize in Medicine and Pathology: H. B. Goodall.  
MacEwan Prize in Surgery: I. M. Grant.

\* With distinction. \* With commendation.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

At the meeting of the Royal College of Physicians of London held on April 3 Lord Moran was re-elected President of the College.

## Medical Notes in Parliament

### Ensuring Cleanliness of School-children

During the Committee stage of the Education Bill in the House of Commons on April 4 Mr. EDE moved a new clause (Power to Ensure Cleanliness). The clause provided that if in the opinion of a medical officer of a local education authority there was reasonable cause to suspect that the person or clothing of a pupil was infested with vermin or in a foul condition, he might cause an examination to be made, and if the person or clothing was found to be so infested, etc., a notice requiring the person and clothing to be cleansed might be served on the parent or pupil. The clause also provided that no girl should be examined or cleansed under the powers conferred by the clause except by a duly qualified medical practitioner or by a woman authorized for that purpose by a local education authority.

The clause was added to the Bill.

### Casualties of British Empire

Mr. CHURCHILL announced on April 4 that during the first four years of war casualties to all ranks of British Empire Forces, excluding deaths from natural causes, were: killed 158,741, wounded 159,219. For the United Kingdom the casualties in the Forces were: killed 120,958, wounded 93,622. Civilian casualties in the United Kingdom during the first four years of war were: killed 49,730, injured and detained in hospital 59,371. These latter figures did not include civilian casualties at sea. Casualties to merchant seamen on British ships during the same four years included 26,317 deaths.

### Smallpox at Mount Vernon Hospital

Mr. VIANT asked on April 5 whether the Secretary for War knew that a soldier who had been successfully vaccinated in infancy and again two years ago introduced smallpox into the Mount Vernon Hospital and spread the infection to 11 other people; and whether, in view of the fact that vaccinated soldiers contracted smallpox during this war, he would either stop all leave of troops to any part of the country where smallpox cases occurred, or make no distinction between vaccinated and unvaccinated men. Sir JAMES GRIGG said he knew that this soldier had been vaccinated successfully in infancy and again in 1942. Owing to the protection thus given him he had a mild attack of smallpox in spite of the fact that the strain was a virulent one. Experience showed that in the interests of the health of the troops it was necessary to maintain the policy he had previously outlined.

### Northern Ireland Parliament

The Government of Northern Ireland has acted promptly on the recommendation of the Select Committee on Health Services by introducing into Parliament a Bill for the setting up of a Ministry of Health and Local Government. The chairman of the committee was Mr. Howard Stevenson, F.R.C.S., who is also one of the Members of Parliament for Queen's University. Moving the second reading of the Bill on April 4 the Prime Minister, Sir BASIL BROOKE, said it gave effect to the main recommendation of the Select Committee on Health Services. The Government were in full agreement with the committee that the time had come to concentrate all these services in one Department under a Minister specially charged with their supervision. He expressed the Government's appreciation of the comprehensive way in which the whole field of health services had been reviewed by the committee. The Prime Minister explained that under Clause 1 of the Bill the proposed Ministry would be responsible for the administration of health, housing, and local government services. The health services could not be divorced from housing conditions.

"We fully recognize," Sir Basil Brooke proceeded, "that the most up-to-date methods for the prevention and cure of illness must be made available to the greatest extent possible for those who require medical attention, and to this end the new Ministry will apply itself. The only method by which the general standard of health can be improved and maintained is by the provision of better housing conditions. These two important matters are closely linked with our system of local government. All these services are interdependent, and the Government consider that the responsibility for health, housing, and local government should rest with one Department. I feel sure that this measure will mark an important stage in our progress towards the creation of better conditions of health and housing and that it will commend itself to the House as a whole."

In the course of the debate Dr. LYLE (Mr. Howard Stevenson's co-member for Queen's University) strongly urged that the new Ministry should include all health services, including health insurance and the inspection and treatment of school-children.

## BUTOBARBITONE

is firmly established as the most generally useful hypnotic. There are occasions when even butobarbitone proves to be inadequate and when recourse to a morphine preparation is deemed necessary but in the majority of cases this product can be fully relied upon as the treatment for those many types of insomnia encountered in general practice. It is because of its proved excellence that 'Soneryl' is frequently described as THE CLASSIC HYPNOTIC.

## ***Insulin A.B.***

Over 20 years ago Allen & Hanburys Ltd. and The British Drug Houses Ltd. decided to pool their resources in regard to the manufacture of Insulin. The object was to make available as quickly as possible, a supply of Insulin in this country.

Insulin A.B. was the result.

It was one of the first British Insulins to be offered commercially to the medical profession and was sold in 5 c.c. vials (20 units per c.c.) at 25/- per vial. Through constant research and improvement in the manufacturing process, the same high quality and quantity of Insulin A.B. is now sold at 1/3. Insulin A.B. conforms to every test and combines the high reputations of two famous British manufacturing houses.

*Joint Licensees and Manufacturers:*

ALLEN & HANBURYS LTD.

THE BRITISH DRUG HOUSES LTD.

## The Services

Surg. Lieut.-Cmdr. W. F. Viret, R.N., and Temp. Surg. Lieut. R. Rhydyen, R.N.V.R., have been awarded the D.S.C., and Acting Surg. Lieut.-Cmdr. B. F. Jackson, R.N.V.R., has been mentioned in dispatches. These names appear in a list of awards published by the *London Gazette* for undaunted courage, determination, and endurance in certain of H.M. ships in many sweeps against enemy shipping in the Aegean under fierce and constant attack from the air, and in maintaining supplies to the islands of Kos and Leros until they fell to superior enemy forces.

The *London Gazette* has announced the appointment as M.B.E. (Military Division) of Capt. W. R. Hart, I.M.S., in recognition of gallant conduct in carrying out hazardous work in a very brave manner.

Capt. (Temp. Major) J. Swinney, R.A.M.C., has been awarded the M.C. in recognition of gallant and distinguished services in Italy.

Surg. Lieut.-Cmdrs. J. F. M. Milner and T. Colver, R.N.V.R., have been awarded the R.N.V.R. Officers' Decoration.

### CASUALTIES IN THE MEDICAL SERVICES

*Wounded*.—War Subs. Capt. W. Foster and J. Wilson, R.A.M.C. *Prisoners of war*.—Lieut.-Col. J. W. Craven, M.C., T.D., R.A.M.C.; Temp. Major M. T. Read, M.C., R.A.M.C.; Acting Major V. Bennett, R.A.M.C.; War Subs. Capt. D. F. Rees and W. P. Wallace, R.A.M.C.; Lieuts. W. Donaldson and T. Wilson, R.A.M.C.

*Missing, presumed killed*.—Acting Surg. Lieut.-Cmdr. B. F. Jackson, R.N.V.R.; Temp. Surg. Lieuts. H. C. Llewellyn and J. H. Wainwright, R.N.V.R.

*Killed in action*.—Capt. C. Greenwood-Penny, R.A.M.C. *Died on active service*.—Surg. Lieut. M. J. Hood, R.N.V.R. *Died at a Casualty Reception Station*.—Capt. E. A. Walker, M.C., R.A.M.C.

## Medical News

The second of the film shows arranged by the Leeds Division of the B.M.A. with the co-operation of the Ministry of Information will be given at the Majestic Cinema, Leeds, on Sunday, April 23, at 3 p.m. The programme will include "Of One Blood," "Man Wounded," and "Plastic Surgery" (in technicolour). All doctors in the area are cordially invited.

Lord Moran, P.R.C.P., will speak on "The Future of Medical Education" to the members of the Polish Medical Association and their guests on Tuesday, April 25, at 4.30 p.m. in the Great Hall, B.M.A. House, Tavistock Square, W.C. Dr. George de Swiet (Hon. President) will take the chair. After discussion the vote of thanks will be proposed by Prof. A. Jurasz, F.R.C.S.(Hon.), Dean of the Polish Medical School, Edinburgh. Medical men and women of all nationalities are welcome.

H.R.H. the Duchess of Kent will attend a special meeting of the National Council for Mental Hygiene at Manson House, 26, Portland Place, W., on Wednesday, April 26, at 3.30 p.m., with Lord Alness in the chair. Dr. Helen Boyle will give an address, followed by the showing of a film.

The annual meeting of the Central Council for the Care of Cripples will be held on Thursday, April 27, in the Cowdray Hall, Henrietta Place, London, W.1, at 2.45 p.m., when Col. Rex Diveley, senior consultant orthopaedic surgeon to the United States Army, will speak on "The Care of Cripples in the United States." Tickets of admission may be had from the Secretary, C.C.C.C., 34, Eccleston Square, S.W.1.

Under the auspices of the British Council and the Ministry of Information a film entitled "Surgery in Chest Diseases" was shown in the Great Hall of Queen's University, Belfast, on March 13. The audience was a large one and included, in addition to the local medical fraternity, many American medical officers and senior medical students.

The William Blair Bell Memorial Lecture will be given at the Royal College of Obstetricians and Gynaecologists, 58, Queen Anne Street, London, W.1, on Saturday, April 29, at 3 p.m., by Dr. H. R. MacLennan. His subject is "Contracted Pelvis in Childbirth." Medical practitioners are invited to attend.

Dr. C. H. Best, F.R.S., professor of physiology in the University of Toronto, has been elected a member of the Athenaeum under the rule for special elections.

The Ministry of Labour and National Service, St. James's Square, S.W.1, has issued a leaflet on the training and resettlement of disabled soldiers, with an appendix on training courses in industrial and other occupations. The various facilities now available for disabled persons are briefly described.

At a meeting of the Medical Society for the Study of Venereal Diseases to be held at 11, Chandos Street, Cavendish Square, W., on Saturday, April 29, at 2.30 p.m., Major D. I. Williams, Major C. S. Nicol, and Lieut.-Col. A. J. King, R.A.M.C., will give a review of experience during the past four years in sulphonamide treatment of gonorrhoea in the male. On Saturday, May 20, Prof. A. Fleming will give an address on penicillin.

The Delhi correspondent of the *Times* reports that Prof. A. V. Hill, M.P., Secretary of the Royal Society, who will return to England soon after a stay of five months in India, has spoken to newspaper correspondents about a forthcoming visit of Indian scientists to England. The delegation will include Col. H. L. Batra, deputy director of the Indian Medical Service, Sir S. S. Bhatnagar, F.R.S., director of the Advisory Board of Scientific and Industrial Research, Sir J. C. Ghosh, director of the Indian Institute of Science, Bangalore, and Professors S. K. Mitra and M. M. Sar, of Calcutta.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In England and Wales the notifications for scarlet fever, diphtheria, and dysentery exceeded those of the previous week by 61, 48, and 35 respectively, but those for measles and whooping-cough were lower by 114 and 113.

The returns for diphtheria were the largest for nine weeks, there being a slight rise throughout the country. The local trends of whooping-cough fluctuated, the drop being most pronounced in the south, and the largest rise in Lancashire 36. After mounting continuously for eleven weeks, the incidence of measles fell, particularly in Kent, the Isle of Wight, and London, where notifications were 81, 69, and 63 respectively fewer than in the previous week. In contrast to the general trend, a rise of 157 in the notifications of measles was reported from Lancashire, Liverpool C.B. recording 40 more cases than last week, Manchester C.B. 23, Abertown U.D. 51, and Golborne U.D. 20.

The incidence of dysentery, which has been at a high level this year, rose by 35, and the total—309—is the largest for any week during the past six months. Since the outbreak of war there has been a rise in the endemic level of this disease. It is probable that many cases escape notification, and consequently the amount of ill-health due to dysentery is much larger than the returns indicate. Centres of infection during the week were: London 55 (Lewisham 22); Lancashire 53 (Blackburn R.D. 31); Surrey 41 (Wimbledon M.B. 25); Northants 30 (Kettering M.B. 27); Middlesex 18; Staffordshire 14.

In Scotland notifications of measles showed a rise of 59 over last week's total, diphtheria a rise of 27, cerebrospinal fever of 22, and whooping-cough of 12, but notifications for scarlet fever dropped by 38, and those of dysentery by 33. The only local increases of note were in the City of Glasgow, where measles notifications mounted by 86 cases, and those of cerebrospinal fever by 19. The largest returns for dysentery were: Lanark County 19, Glasgow 18, Edinburgh 14, Dundee 10.

In Eire the notifications of measles were 32 higher than last week, and those of diphtheria were 12. Diphtheria is widespread, involving forty registration districts. Over half of the cases of measles and nearly half of the cases of whooping-cough were notified in Dublin C.B. One case of typhus was notified in Galway, Oughterard R.D.

In Northern Ireland there was little change in the trend of infectious diseases. 43 of the 78 cases of scarlet fever were reported from Belfast C.B.

### Quarterly Returns for Eire

The birth rate during the last quarter of 1943 was 20.7 per 1,000, being 0.6 below the rate for the December quarter of 1942, but 2.2 above the average for the corresponding quarters of 1938-42. Infant mortality was 81 per 1,000 registered births, and was 9 above the average for the five preceding fourth quarters. The general death rate was 14.8 per 1,000, being 1.6 above the five-year average. Deaths from pulmonary tuberculosis numbered 690, and other forms of tuberculosis 178, respectively 65 and 2 fewer than in the preceding fourth quarter, but 68 and 16 above the five-year average.

The summary for the whole of 1943 is included in the report. The birth rate during the year was 22.3, being the same value as recorded in 1942. The infant mortality per 1,000 registered births was 80; during the preceding five years the rate had varied between 66 and 74. A general death rate of 14.7 per 1,000 was recorded, this being 0.6 greater than in the preceding year and than the five-year average. Deaths from pulmonary tuberculosis numbered 3,366, a decrease of 146 from the total of the preceding year but 484 above the average for 1938-42. 854 deaths were attributed to other forms of tuberculosis, an increase of 19 on the preceding year and 85 above the five-year

average. Deaths from the principal infectious diseases were 1,912, an increase of 237 on the preceding year and 596 in excess of the average of 1938-42. Almost two-thirds (1,191) of the deaths in this classification were due to diarrhoea and enteritis under 2 years; the number registered in Dublin C.B. was 609. The number of deaths from whooping-cough was 297 and from diphtheria 309, these being in excess of the average of the five preceding years by 120 and 75 respectively. 28 deaths were attributed to measles; during the five preceding years the deaths had fluctuated between 77 and 102.

#### Week Ending April 8

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 2,089, whooping-cough 1,558, diphtheria 554, measles 2,343, acute pneumonia 1,003, cerebrospinal fever 78, dysentery 250, smallpox 1, paratyphoid 2, typhoid 9.

#### Where to Treat Scarlet Fever

We have received from Dr. W. A. Bullough, County M.O. for Essex, a memorandum on scarlet fever issued by the Essex Epidemiological Committee for the guidance of practitioners in that county. The memo points out that the mildness of scarlet fever makes the former administrative control largely unnecessary. Scarlet fever is only one of the many manifestations of infection with Group A haemolytic streptococci; there is therefore no justification for isolating in hospital individuals with streptococcal sore throat and a rash, and not those with a similar sore throat and no rash. To do so does not protect the community. But it is impracticable to remove to hospital all with streptococcal sore throats. Whether or not hospital treatment should be given must be decided by the needs of the patient. Cross-infection, largely responsible for the complications of scarlet fever, does not occur if the patient is nursed at home; this is one of the main reasons for advocating home treatment wherever possible.

The possibility of the spread of infection by milk or foods consumed uncooked cannot be ignored, nor can the risk of infecting a woman in the later stages of pregnancy. A case of scarlet fever in a household containing a food-handler or a woman approaching confinement should therefore not be nursed at home. Admission of cases of scarlet fever to hospital should be determined by: (1) the severity of the disease; (2) the home nursing facilities; (3) the employment of another member of the household in the preparation or distribution of food for public consumption; and (4) the approaching confinement, say within one month, of any female in the patient's home.

#### Comment

The memorandum on scarlet fever summarized above is a useful move in tackling the complex problem of streptococcal infection. The occurrence of scarlet fever in an individual requires at least three components: a toxigenic haemolytic streptococcus, a low antistreptococcal immunity which allows the local throat infection, and a lack of antitoxin to the erythrogenic toxin which causes the rash. If antitoxic, but not antibacterial, resistance is present, streptococcal tonsillitis without rash will result. Thus in the same household or school a streptococcal outbreak will be manifested by patients with scarlet fever, others with tonsillitis, and still others who are symptomless carriers of the organism; so that from the point of view of controlling spread of the infection there is little to be gained by isolating the case or cases of scarlet fever and leaving the others at large. The severity of scarlet fever in the past meant that hospitalization was necessary for the proper care and nursing of affected patients. In recent years, with scarlet fever a relatively benign infection and with the realization of the greater need for hospital care of children with measles and pertussis, many local authorities have increased the accommodation for the latter at the expense of scarlet fever. But tradition dies hard, and too many medical men, as well as the lay public, still believe that scarlet fever is a dangerous disease and ought to be nursed in an isolation hospital. In hospital the patient with scarlet fever is usually nursed in an open ward along with other cases of the same disease. Although all have scarlet fever, the infection is caused by half a dozen or more different serological types of the haemolytic streptococcus, and recent work has shown that many of the secondary complications of scarlet fever—e.g., adenitis, otitis media, and relapse—are due to cross-infection with a different serological type of the organism from that causing the original infection. Another drawback to hospital treatment is that the patient frequently acquires a new type of streptococcus which he carries home to infect other members of the family. Thus Forbes (*Lancet*, 1936, 2, 1438) in Brighton has shown that, although home nursing of scarlet fever increased the incidence of secondary cases among household contacts, "return" cases were greatly in excess in the hospital-treated series, and the total incidence of infected contacts was about the same in the two groups.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 1.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1944					1943 (Corresponding Week)

### ANY QUESTIONS?

#### Ending Lactation

**Q.**—Nineteen days ago a woman began a ten-day course of stilboestrol to end lactation. The flow of milk has ceased, but it is still possible to express a drop of milk from the nipples. How long should it be before the breasts dry up completely?

**A.**—If the breasts are not stimulated by attempts at expression, suction, or other local interference, production of milk will probably cease completely within a few weeks. A definite period of time cannot be stated, since it is known that in some women milk, or at least some fluid secretion, can be expressed from the nipples for many years after breast-feeding has been discontinued.

#### Recurrent Ulcers on Tongue

**Q.**—A married woman aged 35, with one child, has had small ulcers on her tongue and buccal mucous membrane for about eighteen months. No septic focus can be found. The teeth are normal; Wassermann negative; fractional test meal and blood count normal. These ulcers occur in crops about every 10 to 14 days, last about a week, and then there is a period of freedom for about a fortnight. When the patient was at the seaside for about a month the lesions disappeared. The diet is good and she is having vitamin C and nicotinic acid. How should I treat the condition?

**A.**—A series of questions on this topic has been answered since this column was opened, and it is obvious that this type of stomatitis is both common and intractable. It is probably due to infection by the virus of herpes simplex, and like other manifestations of this disease it may be aggravated by local irritation, systemic disease, or emotional upsets. The lessening of work and worry probably accounts for the relief at the seaside. A mixture containing 10 gr. of potassium chlorate and 10 minims of tincture of perchloride of iron per dose is an old-fashioned remedy which may be given every four hours to abort an attack when the premonitory symptoms occur. A simple alkaline antiseptic mouth-wash may also be useful. If the ulcers are very painful they may be painted with silver nitrate or gentian violet, or powdered with orthoform in a mixture of chlorbutol and boric acid. To prevent recurrence, vaccination of the subject on the skin of the limbs or buttocks has been recommended, either with the clear fluid obtained from the vesicles or with ordinary vaccinia lymph. It would be wise to consult a virus pathologist before embarking on the former of these procedures, to avoid the risk of transmitting some other infection.

#### Early Closure of Fontanelle

**Q.**—A female infant 15 weeks old has her anterior fontanelle completely closed. Since this is unusual, can you give me any further information on the subject?

**A.**—Early closure of the fontanelle always raises the unfortunate suspicion of microcephaly. Hence it is important to measure the skull carefully and at intervals to make sure growth is taking place. On the other hand, although uncommon, this early closure is apparently quite consistent with a perfectly normal development of brain and skull. If the child is attempting to hold up her head, and otherwise seems normal, the fontanelle closure can be ignored.

#### Veneral Diseases Listed

**Q.**—How many venereal diseases are there? I can name gonorrhoea, syphilis, paradenitis venerea, soft sore, scabies, pediculosis pubis, herpes praeputialis, granuloma venereum. What is soft sore, and where is it described? What connexion, if any, has Ducrey's bacillus with the above?

**A.**—How many venereal diseases there are depends on the definition; officially there are three: syphilis, gonorrhoea, and soft chancre. Many people regard any disease arising directly as a result of

promiscuous sexual intercourse as venereal. The list given seems fairly comprehensive, and the only additions suggested are condylomata acuminata (warts), gangrenous balanitis, and bacterial urethritis (non-gonococcal in origin).

Soft sore is another name for ulcus molle, soft chancre, or chancroid. A description of it will be found in any good textbook of venereal disease. It is an acute localized auto-inoculable genito-infectious disease, characterized clinically by necrotizing ulceration at the site of inoculation; the ulcerations are commonly accompanied by inflammation of the regional lymphatic glands, which show a marked tendency to suppurate. The condition is generally held to be caused by an organism known as *Haemophilus ducreyi*, which is a short bacillus growing in chains (streptobacillus).

#### Keloid Vaccination Scar

**Q.**—I was called to see a baby whose arm I had vaccinated 9 months previously. On the site of vaccination I found a raised pink keloid type of scar instead of the usual somewhat depressed and whitened type. The mother thinks that this may be getting redder and larger. The vaccination ran a normal course at the time without any complications. In ordinary wound healing one associates this type of scar with the so-called "tuberculous diathesis," but there is no history of this. But lymph is associated with calves, calves with cows, and cows with bovine tuberculosis. I have been vaccinating a good number of years now, but have not seen this before.

**A.**—The suggestion that keloid is associated with a tuberculous diathesis has no foundation in fact. Overgrowth of fibrous tissue after trauma or inflammation seems to be an individual idiosyncrasy, and may follow healing by first intention as well as by granulation after infection. The chances of acquiring tuberculous infection by vaccination with calf lymph must be millions-to-one against. The 1928 Report of the Committee on Vaccination states that between 1911 and 1925 no deaths attributable to tuberculosis occurred among 5½ million vaccinated babies, who incidentally would be very susceptible to tuberculous infection. Great precautions are taken against the risk of contaminating vaccine lymph by pathogenic bacteria or viruses. Thus, every animal is examined post mortem after the lymph has been harvested, and the batch is rejected if there is any evidence of tuberculosis or other disease. Again, while the Government Establishment lymph is from calves, other brands—e.g., that of the Lister Institute—are prepared in sheep, which are practically immune to tuberculosis. Keloid is perhaps best treated by radium or x rays, although surgical excision need not give rise to fresh keloid.

#### Primogeniture in Multiple Births

**Q.**—There has been some argument in this part of the world (Deccan, India) as to who is considered legally the elder in a case of twins or triplets. Is it the one that is born first or last? An Indian lawyer of repute is said to have proved to a jury that the last-born is the elder. He produced in court a narrow bottle and two ping-pong balls. He placed them one after the other in the narrow bottle. Then they were "reproduced." The ball that had gone in first was the one that came out last. From this he argued that the last-born was the first conceived, and so the elder.

**A.**—All enduring legal rules are based on practical experience and possibility of proof. Whereas the exact moment of conception is still a matter of guesswork, the exact moment of birth can nearly always be fixed by evidence. Primogeniture is therefore a satisfactory test of seniority in many systems of law apart from ours, without doubt also in that of the ingenious advocate's forefathers.

#### Size of Penis

**Q.**—I have been asked by several patients during the past year or two whether "sex-gland treatment" will increase the size of the penis. In most instances potency has been normal, but the patient has the impression that the penis is abnormally small. Has the male hormone any effect in such cases?

**A.**—The size of the penis varies considerably among normal men. It is therefore probably determined genetically, as well as endocrinologically, and it is well known that, in addition to the concentration of hormones in the blood, the intrinsic responsiveness of the tissues, or organ, determines the final result of the hormone stimulation. In these circumstances, therefore, it is unlikely that the administration of testosterone would have any effect.

Quite apart from the reality of the dimensions, many men suffer from an inferiority complex, especially in relation to the genitals, and imagine that their penis is smaller than it should be. In the presence of normal potency reassurance on this point, with some explanation of the psychological mechanism, is often sufficient. Where potency is psychologically impaired, more extended psychotherapy is necessary. Where the penis is small because of hypogonadism, testosterone therapy is of benefit. It may be administered by injection of 25 mg. testosterone propionate three times weekly, or by methyl testosterone tablets, 5 mg., dissolved under the tongue t.d.s., both procedures to be carried out for some months; or by

the subcutaneous implantation, under local anaesthesia, of 6 tablets of 100 mg. testosterone, the effect lasting six to twelve months. This treatment, however, will not increase the size of the testes and may even diminish them by pituitary inhibition. Should, therefore, the endocrine disorder be due to a primary pituitary deficiency, the testosterone treatment should be followed by, or combined with, gonadotrophic therapy.

## INCOME TAX

### Sale of Property: Tax on Civilian Earnings

M. G. recently sold a house, making £300 profit on the sale. Is this liable to income tax? Should he be paying tax on civilian earnings up to June, 1942?

\*\* Assuming that the house was not bought with the intention of selling it to make a business profit out of it, the £300 represents a "capital" profit and is *not* taxable. Apparently the civilian earnings ceased at June, 1942; if so no tax would be payable thereon for a subsequent period, but M. G. would normally be liable to discharge any tax due for the period to that date, and there might be some delay on the part of the authorities in applying for the payment. If, however, tax on civilian earnings remains unpaid, M. G. should ask for it to be held over as he would seem to have a claim under Section 6 of the Income Tax (Offices and Employments) Act, 1944, for relief to the extent of the unpaid tax.

### Rent for Consulting Rooms

"DELTA" started a consulting practice a year ago, living in temporary accommodation at £2 2s. to begin with and subsequently renting a furnished house at £5 15s. 6d., as a fixed address and telephone number were essential. What rent can be set against his professional receipts?

\*\* The normal basis of calculation is to apply the ratio of private to professional use, and "Delta" would find it difficult to avoid that basis even on appeal. So much depends on the facts of the case that any general rule would tend to mislead. We can only advise him to divide the rent according to the number and value of the rooms used respectively for private and professional purposes—remembering that the ground floor front is the most valuable part of the premises.

### "Pay as you Earn"

A. R. asks whether a medical man acting as an assistant on a monthly salary comes within "pay as you earn."

\*\* Yes.

### "Pay as you Earn": War Bonus.

M. S. has received an increase in remuneration to salary £550 plus £100 allowance and £49 11s. war bonus, total £699 11s., as from March, 1944.

\*\* He comes within the "pay-as-you-earn" arrangements as from April 5, 1944; the £600 limit under the 1943 Act was removed by the Act passed last month. The war bonus is liable to tax in the same way as the salary.

## LETTERS, NOTES, ETC.

### A "Super" Vitamin: Disclaimer

Sir FREDERICK GOWLAND HOPKINS, O.M., F.R.S., writes: During last few days a statement has been made in certain organs of Press that I am devoting my remaining years to the study of a "super" vitamin. This statement has implications which are not justified, and has caused me some distress. I should be most grateful if you could spare space in your columns to say that it is entirely untrue.

### Erythema Nodosum

Dr. H. GUY DAIN (Birmingham) writes: In "Any Questions?" of April 1 (p. 481), under the heading "Erythema Nodosum," is the statement that "by the time the skin lesion appears it is too late to use sulphonamide treatment." This is contrary to my experience that in many cases of streptococcal origin almost dramatic cures have been obtained by the use of the original sulphonamide. It is only fair to say that the course of other cases has not appeared to be influenced.

### Argyrol and Ephedrine in Saline

RONA LABORATORIES Ltd. (London, N.W.2) write: In your issue of March 11 Messrs. E. W. Barstow and T. D. Whittet, writing on the mixture of argyrol and ephedrine in normal saline, refer to "the proprietary article." This obviously means our nasal drop "argotone," and we ask the courtesy of your column to comment on their statement. Anyone who has read the communication from Messrs. Barstow and Whittet might well be under the impression that the mixture prepared according to their own process and the proprietary article are "indistinguishable." If, however, one reads carefully a subsequent article signed by the same authors and published in the *Pharmaceutical Journal* of March 25 (p. 121), it can

be seen that the preparation made according to their process shows a precipitate after six weeks. It is therefore obvious that their preparation is not chemically and therapeutically speaking "indistinguishable" from "argotone," for which we claim, stability for many months under conditions not nearly as good as those prevailing in the Charing Cross Hospital.

### Urinary Damage due to Sodium Bicarbonate?

Dr. E. G. COHEN writes: Mr. J. T. Rice Edwards's letter (Jan. 22) on suppression of urine in a case of partial gastrectomy was interesting. The patient had 14½ g. sulphathiazole (the odd tablet number seems erroneous with even tablet dosage) and presumably 12 to 15 drachms of sodium bicarbonate. On Dec. 2 this patient had, in my opinion, extrarenal uraemia with suppression of urine. No mention is made of delayed shock owing to fluid imbalance, so I take it this factor can be ruled out. The pH of the urine, and whether any debris or crystals were passed in the first specimen, are not mentioned. In the absence of these observations, I would point to a similar occurrence—viz., alkalosis—and with it uraemia as gauged by high blood urea levels—for example, 300 mg. %—in cases of peptic ulcer taking sodium bicarbonate indiscriminately. A normal person requires to ingest some 4 to 5 g. of sodium bicarbonate before passing alkaline urine. In this case the total dosage was about 50 g. over three days. The mechanism of the coincident uraemia is ill understood; I certainly have had no satisfying explanation from the biochemists. Sulphathiazole is the most soluble of the "sulpha" drugs, and though it may have been responsible for urinary damage on a dose of 14½ g., I am of the opinion that the sodium bicarbonate was to blame. The treatment by hydration of the patient was excellent therapeutically.

### Prenatal Examination

In the *Journal* of March 4 (p. 347) a question was asked about prenatal examination. A correspondent draws our attention to the pamphlets issued by the Eugenics Society (69, Eccleston Square, London, S.W.1). One pamphlet is entitled "Health Examination before Marriage," which is addressed "to those about to get married; also to their parents." Notes are issued, too, for the doctor who conducts the pre-nuptial examination, and a schedule is provided, part of which is to be completed by the applicant, and part of it is to be filled up by the examining doctor. The society will issue the schedule to doctors only—not to patients—at a price of 1s. (including the notes for the examining doctor).

### Baptism of Non-viable Infants

Dr. A. PINEY (London, W.1) writes: It is not correct to state that in the Roman Church baptism "may be performed in case of emergency by any adult lay communicant" (April 8, p. 511). The position is that the infant can be validly baptized by any adult who intends to do as the Church does: the question whether the adult be a communicant or not is irrelevant, as are all his (or her) other beliefs and habits. All that is required is the performance of the rite in its bare essentials, together with the proper intention. Furthermore, there is nothing to restrict this power to adults: prudent adolescents—e.g., probationer nurses—can baptize validly. The baptism of premature infants, either *sub conditione* or absolutely, is not covered by a rule as simple as you suggest. It is safe to say: if the child is obviously alive, it can be baptized absolutely, but if there is any doubt, baptism must be conditional—i.e., "If you are alive, I baptize you, etc." May I refer those who wish for accurate information on this and similar matters to *The Catholic Doctor*, by Father A. Bonnar, O.F.M.

The Rev. A. WILSON (Newcastle-upon-Tyne) writes: I have read with interest the reply given under "Any Questions?" on the subject of advice to be given as to baptism in the case of non-viable infants (April 8, p. 510). The reply is, I think, in some respects inaccurate, and perhaps doctors who are interested in this point might like to know Anglican and Roman teaching on the point. (1) From the standpoint of moral theology the separate existence of the child is not judged by whether it "gave signs of life after being completely free from the mother," but from the moment of the infusion of the rational soul, generally held to be at, or shortly after, conception. Therefore not only must baptism be given, if necessary, before actual birth (in this case by the doctor or midwife), but also to any prematurely delivered product of conception. (2) In case of emergency baptism may be given not only by "any adult lay communicant," but by anyone, not even necessarily himself baptized, so long as he has sufficient use of reason, and employs the right matter and form. It is, of course, *preferably* to be given by a cleric before a lay person, and preferably by a baptized person before an unbaptized.

### Corrigendum

The visual angles described in Mr. H. C. Weston's letter on characteristics of vision in fine work (April 15, p. 539) should have been given in seconds (""). The correct references are: 3.125" (secs.), 24.14", 3.39", 24", and 25".

LONDON SATURDAY APRIL 29 1944

## WARTIME INCIDENCE OF AND MORTALITY FROM RESPIRATORY TUBERCULOSIS

BY

PERCY STOCKS, M.D., D.P.H.

(General Register Office)

AND

E. LEWIS-FANING, B.Sc.Econ., Ph.D.

(Medical Research Council)

It is now possible to reach certain tentative conclusions about the sources of the increase in deaths from respiratory tuberculosis which occurred in 1940-1, although some years must lapse before statistical data are available to complete the picture. It may indeed transpire that other disturbing factors come so complex that we must remain content with such an incomplete answer as can now be given.

Until recently it was difficult to link together the statistics of notifications and deaths in order to estimate the rate at which new cases of respiratory tuberculosis subsequently proved fatal. One of us (Lewis-Faning, 1943) has now published some data of the durations between notification and death for patients who died of the disease in the County of Middlesex in the periods 1937-9 and 1940-1, by means of which the rates of dying in the immediate pre-war period can be estimated. Another helpful analysis of the survival rates of patients from whom tubercle bacilli were found has been published by C. Thompson (1943). In the notes which follow we have endeavoured to draw from the data at present available such conclusions as seem possible about incidence and mortality from respiratory tuberculosis during the first four years of the war. Throughout the discussion the term "notifications" means the formal notifications during life, and excludes the deaths of persons who had not previously been notified and answers from one area to another.

declined continuously from 1925 to 1939, except in two of the "influenza" years, 1931 and 1937. Deaths declined less regularly, interruptions occurring in 1924, 1927, 1929, 1931, 1933, and 1937, when influenza was epidemic. The ratio of deaths to the notifications of the year preceding showed no consistent change between 1922 and 1939, ranging between 0.46 and 0.54. With the ratio based upon a simple weighted summation of the notifications in the current and three preceding years the variation was still smaller (0.473 to 0.527 in the period from 1922 to 1939). It is evident from this that more reliance can be placed on the statistics from 1922 onwards than was the case in the early days of tuberculosis notification, and that they are reasonably consistent with those of deaths. A sudden increase in these ratios occurred in 1940, to 0.61 and 0.59 respectively, followed in 1942 by a fall below the normal range of values, to 0.47 and 0.48, somewhat greater than that which occurred in the years following influenza epidemics. A further fall in the ratios in 1943 is indicated by the provisional figures. It may be that the ratios will not return to the pre-war level owing to the effects of selection for national service on the one hand and radiography on the other in bringing sligher cases into the notification net.

The Middlesex deaths from respiratory tuberculosis in 1937-9 of persons who had been notified at some time and were known to the local authority were found to be distributed according to duration since notification as follows: Less than 1 year, 42%; 1 year but less than 5, 45%; 5 years but less than 10, 10½%; 10 years and over, 2½%. Assuming the 60,443 deaths of notified persons in England and Wales in those years to have had the same proportionate distribution, they can be related to the numbers of notifications from which they were derived if we also make the simplifying assumption that the durations of 10 years and over were all included within the range 10-15 years. The latter assumption cannot introduce an appreciable error owing to the small frequencies after 15 years and the form of the frequency curve. The results of this calculation are shown in Table II.

TABLE II.—Rates of Dying from Respiratory Tuberculosis after Notification in Four Duration Groups (1937-9 data)

Years from Notification	Deaths of Notified Persons, 1937-9		No of Notified Persons from Whom Derived†	Death Rates per 100 Originally Notified	No Dead of Respiratory Tuberculosis at End of Interval out of 100
	Middlesex*	England and Wales

\* Provisional estimates.

† Estimated as 90% of total deaths, the proportion in 1929-33.

‡ (Current year + twice preceding year + sum of 2nd and 3rd years back)

Table I shows the numbers of notifications and of deaths of notified persons in England and Wales in each year 1923 to 1942, and provisional figures for 1943. The notifications

Fitting a smooth curve to the numbers of notified persons dead of the disease at the end of 1, 5, 10, and 15 years, the "trial" rates in column 1 of Table III were obtained. These rates were then applied to each year separately, as in Table IV, and the resulting deaths in 1937, 1938, and 1939 were aggregated at the four age groups and compared with the numbers required by the Middlesex proportions. The curve was then slightly adjusted so as to produce the exact aggregates required in 1937-9, the adjusted rates being as shown in columns 2 and 4.

TABLE III.—*Rates of Dying from Respiratory Tuberculosis in Each Year After Notification (1937-9 data)*

Interval After Notification (years)	Estimated No. Dead of the Disease at End of Interval Specified out of 100			No. Expected to Die of the Disease during Each Successive Year out of 100 originally Notified
	England and Wales		Middlesex	
	(1) Trial	(2) Adjusted	(3) Adjusted	
0-..	22.2	22.2	18.5	22.2
1-..	31.2	31.2	26.5	9.0
2-..	37.2	37.5	32.1	6.3
3-..	41.5	41.8	35.9	4.3
4-..	44.2	44.5	38.3	2.7
5-..	45.7	46.0	39.8	1.5
6-..	46.8	47.1	40.9	1.1
7-..	47.6	47.9	41.7	0.8
8-..	48.2	48.5	42.3	0.6
9-..	48.6	48.9	42.7	0.4
10-..	48.9	49.2	43.0	0.3
11-..	49.1	49.4	43.2	0.2
12-..	49.3	49.6	43.4	0.2
13-..	49.4	49.8	43.5	0.2
14-..	49.5	49.9	43.6	0.1

The rates indicate that in the pre-war period about 22% of persons with respiratory tuberculosis died of the disease within a year of being notified, 44½% within 5 years, and 49% within 10 years; and that 50% died eventually of the disease. With this may be compared the survival rate of about one-seventh for sputum-positive patients after 10 years as found by Thompson (1943).

As a check on this result the same process was carried out for the County of Middlesex. In 1938-9 deaths of notified persons formed 91% of the total deaths of residents from respiratory tuberculosis, this being the same proportion as in England and Wales; it was assumed, therefore, that in the period 1922-37 the national proportions applied also to the county. Since the county population was growing rapidly in that period the notified persons from whom the deaths in 1937-9 were derived had not all been notified within the county, and it was assumed that the immigrant population had experienced in each year the notification rates of England and Wales less Middlesex. The result of this calculation is shown in column 3 of Table III. As might be expected in this southern county, whose standardized death rates in 1931-5 were only 85% of the national rate at ages 15-35 and 87% at ages 35 and over (Registrar-General, 1935), the rates of dying after notification were consistently lower than for England and Wales by about one-seventh, though the form of the two curves was very similar. Within 5 years 38% died of the disease in Middlesex compared with 44½%; and 43½% died of it eventually instead of 50%. It seems probable from this comparison that local variations in mortality are largely due to fatality differences and not necessarily to differential incidence. If the data were available for similar calculations in Wales, Liverpool, Tyneside, and other areas of high standardized mortality, the resulting fatality rates would no doubt be found to be greater than the national figures, which represent averages for the whole country.

On the assumption that the deaths which occurred in England and Wales in each year 1935 to 1942 were related to the numbers notified in the successive periods mid-1925 to mid-1926, etc., in accordance with the adjusted rates of dying in Table III, the expected deaths would have compared with the numbers of deaths of notified persons actually registered as shown in Table IV. Provisional data are also given for 1943.

The last line but one in the table shows that there was an excess of about 440 deaths in 1937 over the expected number, followed by a deficiency of about 770 in 1938, due in all probability to the earlier deaths of many tuberculous persons brought about by the "influenza" epidemic at the beginning

TABLE IV.—*Estimated Numbers of Deaths of Notified Persons from Respiratory Tuberculosis expected at each Duration and of all Durations, 1935 to 1943, compared with Total Annual Deaths Registered*

Interval After Notification (years)	No. of Deaths (in Hundreds) expected from Pre-war Rates of Dying, in

Deaths of unnotified persons, ..	21.3	22.4	20.4	18.1	17.5	21.8	27.8	25.2	(25.0)	

of 1937. Had there been no war and had notifications continued to fall at the same rate as between 1933-5 and 1937-9, the numbers in successive years 1940 to 1943 would have been 35.0, 33.8, 32.6, and 31.4 thousands instead of the number shown in Table I. The resulting deaths would then have been as follows, instead of the expected numbers shown in Table IV:

Interval after Notification	Deaths (in Hundreds) Expected if Downward Trend of Notifications had Continued			
	1940	1941	1942	1943
0-..	77.6	76.4	73.7	71.0
1-..	32.8	31.5	31.0	29.9
2-..	24.4	22.9	22.0	21.7
3-..	17.0	16.7	15.7	15.0
4-..	10.6	10.7	10.5	9.8
5-..	19.5	18.5	17.9	17.5
10 and over	5.3	5.2	4.9	4.9
Total	187.2	181.9	175.7	169.8
Deficiency below deaths expected from actual notifications	-4.4	-7.7	-18.9	-29.7

This shows that if the rate of dying from the disease after notification remained unchanged, the extra incidence of respiratory tuberculosis brought about by war conditions must have resulted in about 1,200 deaths in 1940-1, about 1,900 in 1942, and about 3,000 in 1943, a total of 6,000 in excess of the number which would have resulted had the pre-war trend of notifications continued undisturbed. The increased fatality during 1940-1 would not affect this number considerably, since the bulk of the increase in incidence occurred later. While it is probably true that part of the increase in notifications has been merely due to a roping in of people suffering from the disease who would in normal times have escaped notification, there has been no compensating fall in the deaths of unnotified persons during the war, but rather a rise, as shown at the foot of Table IV. The reason for this may be that more immigrants have come into England and Wales from countries where tuberculosis incidence is high, and also that excessive movement of the population from place to place has led to more people escaping notification.

In addition to the 6,000 deaths attributable to excessive wartime incidence of new cases, Table IV shows that an excess of deaths over the numbers expected from the actual notifications occurred in 1940-1 amounting to 4,210, and this was followed by a deficiency in 1942-3 amounting to 2,200. The

only satisfactory explanation of this happening (which was anticipated, since it has been seen before in lesser degree in years with influenza epidemics and cold winters) is that the rate of dying of patients already notified was temporarily enhanced by the hard conditions of 1940-1. By this shortening of the normal survival period at least 2,200 notified patients apparently died of the disease during 1940-1 who under normal conditions would have not died of it until 1942-3. Probably the number was several hundreds greater than this, for tuberculosis deaths in the December quarter of 1943 were considerably increased by the influenza epidemic of November-December, thereby neutralizing part of the deficiency which would otherwise have been apparent for 1943 as a whole. That a considerable temporary increase in the short-term fatality rate did occur in 1940-1 and that it was followed by a compensating fall below the ordinary level in 1942-3 is shown by the last column of Table I. From 0.51 in 1936-9 the ratio increased to 0.59 in 1940 and 0.56 in 1941, falling to 0.48 in 1942 and 0.47 in 1943.

In the work on Middlesex deaths by one of us (Lewis-Faning, 1943) it was found that in 1940-1 1,610 deaths from respiratory tuberculosis of notified persons were distributed according to the interval since notification as follows: 701 under 1 year, 665 after 1 but less than 5 years, and 244 after 5 or more years. If all the deaths of notified persons in England and Wales during 1940-1 were similarly distributed the composition of the excess of 4,210 deaths according to interval since notification must have been as shown below.

	Under 1 Year	1-4 Years	5 Years or more	All Durations
Actual deaths 1940-1 in Middlesex proportions	18,430	17,480	6,420	42,330
Expected deaths (Table IV)	16,440	16,830	4,850	38,120
Excess over expectation	1,990	650	1,570	4,210

These figures are quite consistent with the supposition that some 2,500 patients died in 1940-1 instead of in 1942-3. Table IV shows that there must have been at least 10,000 patients notified less than a year living in 1940-1 who were expected to die in 1942-3, and 1,990 of them might well have died earlier; similarly there must have been at least 7,000 patients notified 1 to 4 years living in the first period who were expected to die in the second, and 650 of them might have died earlier as a result of the severities of 1940-1. This would more than account for the transfer of 2,200 deaths; and the rest of the increase could be explained by breakdown of patients in whom the disease had become quiescent and who in normal conditions would not have died of the disease at all, or not in this country. It is not to be supposed that in the disturbances of 1940-1 the Middlesex proportions were exactly representative of those in the country as a whole and that what happened was precisely as suggested above. The purpose of quoting the Middlesex 1940-1 data is mainly to correct an impression given by the paper in which they were analysed that they seemed inconsistent with the view that any considerable part of the increase in tuberculosis deaths in the early part of the war was attributable to shortening of life of patients who already had the disease. One would hesitate to proceed further than Table III in applying the method of analysis used here to those data, owing to the disturbed state of residence of the population of that county in 1940-1. But this more comprehensive analysis, based as it is on data for the whole country (where the objection does not apply) suggests that about 2,500 of the deaths in 1940-1, or three-quarters of the excess over the 1938-9 total, were accounted for by shortened duration.

#### Summary

In the period 1923-39, despite the rapid fall in the numbers of notifications of and deaths from respiratory tuberculosis, the average expectation, for a person just notified, of eventually dying of the disease remained remarkably constant at approximately one-half in England and Wales as a whole.

Immediately before the war the average expectation of dying within a year of notification was about 22%, and within 5 years about 44%. For Middlesex County the curve showing the rate of dying after notification was similar to that for the country as a whole, but at a lower level—43% eventually dying of the disease

instead of 50%. This lower fatality corresponds with the lower standardized death rates in the county as found for 1931-5.

Had the incidence of new cases continued to decline as in the pre-war period, instead of increasing, some 6,000 fewer deaths would have occurred during 1940-3 under normal conditions.

Owing to a temporary rise in short-term fatality during the severe conditions of 1940-1 some 2,500 notified patients probably died in those years instead of in 1942-3. Another 1,500 notified persons and about 1,000 unnotified persons who in normal circumstances would not have died of the disease at all in this country must have died of respiratory tuberculosis during 1940-1.

## THE RELATION OF DERMATOLOGY TO PSYCHIATRY\*

BY

F. F. HELIER, M.D., F.R.C.P.

Lieut.-Col., R.A.M.C.; Command Dermatologist

The expansion of psychiatry in the Army has provided opportunities for liaison with other branches of medicine such as have never been available before, and, under the controlled and standardized conditions of Army life, the importance of the personality factor in all diseases is being more and more appreciated. It was therefore with great pleasure that I accepted an invitation to present the dermatologist's point of view to a gathering of psychiatrists; nor is this inappropriate, as, embryologically speaking at least, psychiatry is an offshoot of dermatology, and a fundamental association persists into adult life.

#### The Hypersensitive Subject

L. Brocq divided skin conditions into two groups—skin diseases proper and skin reactions. The former usually have a specific aetiological agent which produces a characteristic lesion in anyone affected. Thus the *Spirochaeta pallida* causes the same kind of chancre in any uninfected person, and prolonged exposure to spinning-oil a classical epithelioma. When these lesions are treated adequately the condition is finished with and there is no increased likelihood of a fresh attack. In contradistinction to this, a skin "reaction" depends for its characteristic type on the make-up of the patient and not on the specificity of the external factor. Whealing may be produced in one patient by tinned salmon, in others by getting warm or cold or rubbing the skin, and in another because he is upset psychologically, but most people do not develop wheals at all under normal conditions. Here the personality of the patient is all-important; only if he is made in a special way will he produce a wheal with his characteristic stimulus, otherwise it will have no effect at all. A reaction may be simple, like flushing, or more complicated, like eczema or psoriasis, but all behave in essentially the same way. Thus one patient may develop psoriasis whenever he has a sore throat; another if his skin is injured by a scratch; another whenever he undergoes a period of stress, as instanced by one man I recall whose rash recurred every time he took a medical examination. The eczema patient similarly reacts badly to adverse circumstances. Soon after quitting the protection of the womb and meeting the troubles of the world for the first time, he develops infantile eczema. He may adjust himself to his environment, but the rash is likely to return at puberty, at the menopause, and in old age, or at any other time when things go against him. Just as some people react to stress with indigestion, headache, or asthma, so this patient reacts with an attack of eczema and his fellow patient with psoriasis or urticaria; they do so because they are made that way. It is an old gibe that "it is nice to be a dermatologist, because your patients never die, they never get you up in the night, and they never get better." This latter is only too true in many instances, because you can't cure a man of his own personality.

\* Based on a talk given to a meeting of psychiatrists.

### Eczema

Are there any indications of such an abnormal constitution apart from the appearance of a rash? Undoubtedly there are, and they are well illustrated in patients with eczema. The hypersensitivity of the skin of eczema patients is only one aspect of a generally hypersensitive make-up. Such patients are above the average intelligence, but admit to being highly strung, over-conscientious, and worriers; they possess terrific drive, and are very active, both mentally and physically. They have a tremulous tongue and bright eyes almost suggesting exophthalmos in marked cases, they move quickly, and when asked to undress do so with great speed, only hampered by the marked tremor of their hands. They have been well described as 100-horse-power engines in 60-horse-power bodices. Even in infancy the picture is typical. The child is obviously intelligent, full of unbounded energy, but rather irritable; a familiar trio in the dermatologist's room is the worn-out, over-anxious mother, the worried short-of-sleep father who is continuously retrieving his restless son and telling him not to scratch, and the child who is the picture of health apart from his scratched face and his resentment at being interfered with. The following description by a psychologist portrays just such a child, though actually it is describing the child with asthma:

"He has an intelligence much above the average; he is irritable and aggressive, quick to respond; he is over-anxious, insecure, un-selfconfident. As a result of his insecurity he often appears at first sight repressed and submissive, but even then there is generally an air of subdued tension about him, and, given the opportunity for freer and more confident self-expression, he becomes aggressive and domineering. He is, in fact, the type of child who makes more demands upon his parents, particularly his mother, than almost any other. He is an intelligent individual who twists her round his finger, aggressive enough to get his own way and anxious enough to demand her continual attention." (Rogerson, 1943.)

### The Problem of Treatment

The recognition of the type of patient is easy, but how can one help him? The application of ointments and x rays will literally only touch the surface of the condition; if we are to obtain permanent benefit we must tackle the patient as a whole and consider his personality and environment. The problem may be divided into two parts: the discovery of the immediate factor which caused the present attack, and the wider aspect of the adjustment of the patient's attitude to life and his skin condition. The former is often surprisingly simple; the patient is only too willing to pour forth his troubles to a sympathetic listener, and, helped by a few judicious questions, soon reveals marital or financial worries, a period of strain, or some emotional shock which seems to bear a direct relation to the current attack and which the patient is ready to accept as such. The solution to these problems is often possible, using common sense and a little persuasion. More difficult is the problem of altering the patient's outlook and mode of existence so that he may be protected from stresses and strains which his hypersensitive make-up cannot support. One aims at giving the patient insight into his condition, reassuring him that it can be controlled if he goes about it the right way, and modifying his environment. In many cases this common-sense psychology will succeed; but in others one is faced with a severe anxiety state, and it is sensed that there are hidden stresses in the patient's mind that one has failed to expose. One is often reduced to giving these patients bromide—a confession of failure—and it is in such cases that one turns for help to the trained psychiatrist.

I would here refer to an experiment in rehabilitation which the Army has started and which I have been privileged to supervise. An auxiliary hospital has been set aside for chronic skin cases which have failed to stand up to Army life. The object of the scheme is twofold: first, the men have a set routine of work of at least five hours a day doing domestic work, workshop jobs, gardening, harvesting, etc. This is to keep their minds occupied so that they do not sit and brood all day over their skins. Secondly, they do fairly strenuous work, including P.T., which keeps them physically fit and gives them confidence that their skin will stand up to exercise, even though it may make them sweat; and thus the man returns to his unit unafraid of the consequence, and the shock of the transition

from the shielded atmosphere of the hospital to active life is graduated. I err on the side of risk rather than caution, and let eczema patients bathe and seborrheic sweat; if I would rather have a man break down in hospital, if he is going to do so, than when he has got back to his unit. The experiment is only in its infancy, but so far the results seem to justify it.

While discussing eczema I must mention one important symptom—itching. If anyone doubts that itching can be produced purely by psychological factors, he has only to observe a class of students to whom one has demonstrated a head full of lice. It is significant that the word "itch" also means "desire," and that a patient will often say that he has had "lovely scratch"; such phrases derive from the pleasurable element in scratching, which may weigh heavily against the patient's expressed desire to get better. In severe cases of itching the patient may work himself into a fury of scratching utterly uncontrollable and increasing until finally he falls into an exhausted languor, the whole process clearly justifying the description of an orgasm of scratching, with all that this implies psychologically. Certain sites are peculiarly prone to itch, especially the anus and vulva. Part of the reason for this is that these areas are moist from sweat and soiled with irritating faeces or glycosuria, etc.; once irritation has started in an area the threshold for stimuli is lowered because the patient's attention is concentrated on the part, and this leads to further scratching, which in turn increases the itching. I need not, however, emphasize the psychological significance of these sites and the problems associated with the patient's absorption in them.

### Nervous and Emotional Factors

Rosacea is a condition which demonstrates very clearly the importance of nervous factors in the development of skin manifestations. Rosacea has been described as pathological flushing, and any factor which increases the redness of the face may precipitate or aggravate the condition in a predisposed person. Such factors are the excessive intake of alcohol or tea, often with an associated gastritis; the menopause and pelvic disorders; local sepsis in teeth or antra; and exposure to extremes of heat and cold, especially when the latter is combined with wind. One or more of these are usually emphasized in discussions on the cause of rosacea, but the most important factor—the psychological one—is often neglected, though it is obvious that blushing is closely bound up with emotional reaction. Actually, investigation of rosacea patients rarely fails to reveal an abnormal personality. They are usually of the shy retiring type, unwilling to make social contacts, self-conscious, and sensitive about their appearance, so that as the condition progresses they tend to retire more and more into their shells. The commonest type of patient with rosacea in my experience is the unmarried schoolmistress from 35 to 45 years old. Klaber and Wittkower (1939) investigated a series of 50 cases of rosacea and found that "35 of the cases (in contrast to 11 of the control group) described themselves as quiet, reserved, and serious-minded children. They disliked parties, games, and group activities; preferred to play alone, and were fond of reading and thinking. They made few friends. . . . 15 rosacea patients, in contrast to 39 controls, described themselves as lively, sociable, and care-free children. . . . The onset of rosacea was preceded in 13 cases by an acute emotional trauma, serious enough to be regarded as a precipitating factor, and in 20 cases by prolonged emotional stresses." The following case of mine illustrates the importance of the psychological approach:

Miss A. (35), a schoolmistress, is one of four sisters. The other three are married, but she had to break off her engagement in order to look after her father and mother. She lived with her parents in a large old house which was very inconvenient to run, but her father refused to leave it; Miss A. had to do all the housework when she returned home from school in the evenings. Her sisters traded on her self-sacrifice—particularly one, a first-class hysteric, who periodically came home and went to bed for a week. Miss A. has gradually had to abandon all her social activities, including church work, because of her home ties. Three months ago her father became ill and she sat up every night with him, on top of all her other duties. After six weeks he died, and within two days she developed a fierce rosacea. The outbreak was attributed to the strain of nursing her father.

I suggest that the true explanation is that her father was a great burden to her, and subconsciously she must have desired his death, though, with characteristic overcompensation, she sat up every night during his illness. When he died the fulfilment of her suppressed wish produced a sense of guilt lest she had in some way contributed to his death, and as a result she developed a guilty flush—i.e., rosacea. I explained all this to her and told her that she must live more for herself and move with her mother into a small easily run cottage; this, together with some local treatment, produced a dramatic improvement. It has been suggested that the emotional factor acts upon the face only indirectly through its influence on gastric tone, which has been shown to be related to rosacea (Eastwood, 1934). I do not think that it is necessary to introduce this complication when one remembers how directly flushing of the face is related to nervous influences; and, anyhow, the important thing is that all cases of rosacea should be considered from the psychological aspect.

That worry makes the hair fall out is a popular conception. I would go further and say that all cases of alopecia areata are nervous in origin and that all successes claimed for local treatment are due to suggestion or spontaneous improvement, though I admit that the actual speed of growth of hair is increased by hyperaemia. One could give endless instances of acute or chronic psychological factors causing alopecia, and there is a type of patient who reacts to adversity by losing his hair and is likely to do so repeatedly whenever things go against him. The following case, which was under the care of Dr. Ingram for several years, and which he has allowed me to quote, is a good illustration of the effect of nervous influences.

A. B., an only boy, suffered from alopecia totalis from about 7 years old. He was given a great variety of treatment at the General Infirmary at Leeds, including ultra-violet light, x rays, hormones, etc., without result. The parents, who lived in an isolated house, kept an anxious watch on the boy's scalp, but each morning failed to reveal any growth even to the closest scrutiny. Finally, after several years of treatment, Dr. Ingram insisted that the boy, who was now 14, should be sent away from home. After his first term at boarding school he returned home with a complete head of hair.

Another condition in which a sudden shock or a definite period of strain plays an obvious part is lichen planus. The onset of this disease is often dramatic; one patient of mine had a sudden attack of haematuria and developed lichen planus two days later, while another broke out the next day after answering the telephone and being told that her best friend had been killed. In these and similar cases the emotional factor is the trigger that sets the condition going, and the case is often rapidly cured; when, however, the rash develops after a period of worry or nervous strain, it may require considerable readjustment in the patient's mode of living before a cure can be effected.

#### Hyperidrosis; Warts

Hyperidrosis is a problem of some magnitude in the Army. The usual sufferer is of the active, highly strung type with tremor of his hands and feet—often a good soldier, but relegated to a low category because of his feet. The condition is almost incurable by ordinary means, though it can be controlled to some extent by foot toilet, sodium hexametaphosphate, etc. An indication of the real cause of the condition is given by the following patient of mine:

Cpl. X., a first-class soldier, but Category C because of severe hyperidrosis, had never had any trouble with his feet until 1940, when he was evacuated from Dunkirk. Since then he has had sweaty feet, which he attributed to wearing boots and marching continuously for five days. Examination showed his feet to be offensive, with the characteristic livid hue over the ball and outer side of the feet and heels, "honeycomb" maceration of the soles, and sodden skin between the toes (this latter is often wrongly diagnosed as ringworm). The hands are sweaty and tremulous.

The explanation is obvious: the experience at Dunkirk made him sweat and tremble with fear, and this emotion has persisted in his subconscious and is responsible for the persistence of his symptoms. Here is a real line of attack on this incapacitating condition, but in most cases it is by no means a simple psychological problem even for the trained psychiatrist.

One final condition might be of interest to the psychiatrist—the common wart. Warts are due to a virus, and are transmitted from one person to another by injecting an encysted wart tissue. Despite this, Bruno Bloch maintained that he could cure 75% of warts by suggestion. My own experience confirms this possibility, and everyone will recall instances of warts being cured by methods which border on the magical. We have here apparently a remarkable instance of the course of an infection being modified by a psychological process, though I doubt if the psychiatrists would appreciate being sent all the patients with warts who crowd the skin clinics.

#### Conclusion

This paper is by no means exhaustive, but I hope it will indicate the importance of the psychological approach to dermatology and the close liaison there should be between the dermatologist and the psychiatrist. In the Army there is now ample provision of psychiatrists, and Army specialists of all kinds, having got accustomed to co-operating with them, will surely demand a similar service when they return to civil practice. Unfortunately exigencies of the Service tend to stress the diagnostic aspect. When we return to civil life we shall no longer be able to dispose of our difficult cases by boarding them to Category E, and it is among these that in the future I hope to see the psychiatrist playing a large part in dermatology.

## SICKNESS RECORDS OF NURSES IN A GENERAL HOSPITAL

BY

JOYCE WRIGHT, D.M.

(University College Hospital Medical School, London)

The attention of hospital administrators in various countries has from time to time been directed to the health of nurses and to the protection of hospital personnel from the occupational hazards of their work. While considerable interest has been shown in the occurrence and prevention of tuberculosis among nurses, comparatively few investigations are recorded on the nature and incidence of other ailments.

"The Maintenance of High Standards of Health in the Nursing Community" was discussed at the Congress of the International Council of Nurses in 1937. Pietzcker (1937) gave the interim two-year report of the Health Statistics Committee, whose research work comprised a five-year plan, starting in 1934. Questionnaires were sent to the best-known nursing schools in 32 countries. They were evidently having educational value, for a 44% return was made in 1935, compared with 22% for the previous year; and hospitals were found to be introducing new measures with regard to staff health.

The United States National League of Nursing Education (1938) in its *Study of the Incidence and Costs of Illness among Nurses* published the results of a survey on the illnesses of student and graduate nurses. Two hundred and twenty-three nursing schools, comprising 17,364 student nurses and 8,794 graduate nurses, returned reports for the year 1937-8. The Study disclosed certain significant facts, among them the following:

- (a) In the country as a whole student nurses had more illness than graduate staff nurses; the annual average number of days of illness per student nurse was 8.3 and per graduate nurse 6.6.
- (b) Clinical students were ill more than preclinical students. The annual average number of days of illness per clinical student was 9.2 and per preclinical student 5.2.
- (c) Students on the paediatric service or on the communicable diseases service had a higher illness rate than clinical students on all other services.
- (d) Average days of illness for both students and graduates were highest in January, February, and March.
- (e) The annual financial cost of hospital treatment for student and graduate nurses was estimated at 3 to 4 million dollars.
- (f) Health records of graduate and student nurses, as measured by days off for illness, were not so favourable as those of college students and of women in the clerical, industrial, and teaching fields.

A comparative study of the health of student nurses and girl college students was made by Diehl (1935), who kept records of minor and disabling illnesses among both groups during one school year. He included only those illnesses which were occasioned by acute infections or by other conditions which might be related to the work. Illnesses incurred by nurses during college vacations were not counted. After allowing for certain factors which might give rise to differences in the sickness rates of the "Nurse Group" and the "College Group," Diehl concluded that the incidence and severity of illness among the student nurses was distinctly greater than among college girls living in a comparable environment. He found that respiratory infections were 2.8 times as frequent among student nurses as among college girls, and superficial pyogenic infections 5.2 times as frequent. He attributed this to the fact that the nurses were more exposed to infection, both cutaneous and respiratory, than other students; that they had longer hours of duty; and that they were deterred from reporting minor illnesses immediately, since they had to make up time lost.

Among nurses at Cook County Hospital, Rhoads and Afremow (1938) found that acute throat infection was the greatest single cause of illness. They followed one class through its period of training and found that, on the average, each nurse was off duty for sickness for 75.5 days (7% of total training time) and that about 27% of this absence was attributable to upper respiratory tract infection. They analysed also the ward distribution of the nurses with sore throat, and discovered that where exposure to infectious diseases was greatest—i.e., the Children's Hospital and the Contagious Diseases Hospital—the incidence of throat infection was highest.

In a recent article Court (1943) reported that among the nurses of an E.M.S. sector hospital respiratory infection took first place both in days lost and in numbers of staff involved. The percentage incidence of staff so affected was 38 in 1941 and 45 in 1942, and was higher among nursing auxiliaries and assistants than among the professional group of trained and student nurses. He regarded the prevention of respiratory infection among hospital personnel as an urgent and important problem.

Sickness figures for a general hospital are given by Branson (1933) in his report on the health of nurses at St. Bartholomew's Hospital for 1922 to 1931. As an index of health he regarded the total independent attacks of illness occurring annually (especially when related to the number of nurses at risk) as more reliable than the figure for "nurse-days" lost. He found that the infections comprised by the terms "sepsis," "catarrhal disease," and "sore throat" provided, in a

### Sickness Records of Nursing Staff in a London General Hospital

In order to obtain more detailed information the sickness records of the nursing personnel at University College Hospital (London), a general hospital with a training school, have been reviewed for the years 1936, 1937, and 1938. More recent data could not satisfactorily be analysed owing to the various administrative changes brought about by the war. About 80 student nurses entered the school each year; on entry all had a medical examination and a radiograph taken of the chest, and were immunized against diphtheria. Including resident masseuses, radiographers, dietitians, etc., and all grades of nurses, the numbers "at risk" were 410 for 1936, 475 for 1937 and 500 for 1938. The analysis was made from the "day book" of the resident medical officer and the home sister who see sick staff each day, and from case records of those who were admitted to the hospital wards. In addition, data were obtained in some cases from infectious diseases hospital and sanatoria to which nurses had been sent for treatment.

TABLE 1.—Number of Attacks and of Days Off Duty for Sicknesses lasting Less than 100 Days

Nature of Sickness	1936		1937		1938	
	No. of Nurses at Risk		No. of Nurses at Risk		No. of Nurses at Risk

descending scale of contribution, about 60% of the nurses' illnesses. The heading "sepsis" covered an ill-defined but large group of septic skin conditions—"septic fingers," similar lesions of the feet, and boils. A considerable majority of these cases were "septic fingers," and apparently a good many resulted from safety-pin pricks. In a fair number the disablement lasted for a long time. The term "catarrhal disease" described the miscellany of respiratory infections, such as "colds," "influenza," and their complications; the peak period for these attacks was in the early months of the year, and accounted at times for a considerable depletion of the available staff.

Tables I and II show in summary form the results of the analysis. Only sicknesses which involved absence from duty are recorded. These are divided into two parts—Table I, those of less than 100 days' duration; and Table II, those of more than 100 days' duration. This time-division is arbitrary, and serves merely to give an indication of the long illnesses of each year.

Table I shows that, taking the three-year period as a whole, pyogenic infections—i.e., boils, styes, whitlows, etc.—took first place both as regards number of attacks and number of days off duty. Of a total of 1,117 attacks, 328 (29.4%) were due to pyogenic infections; and of a total of 14,861 sickness-days, 3,765 (25.3%) were due to this cause. Whitlows accounted for 130 (39.6%) of the attacks of pyogenic infection and for 1,743 (46.3%) of the sickness-days.

days due to it. During the three years who were responsible for 11.6% of all sicknesses and for 11.7% of all sickness-days.

With figures only slightly lower than those for pyogenic infections followed the group of upper respiratory tract infections—"colds," "influenza," and sore throat—with 316 attacks (28.3% of all sicknesses) and 3,598 sickness-days (24.2% of the total). Taken together, therefore, respiratory and pyogenic infections accounted, as in Branson's figures, for nearly 60% of all illnesses and for half the number of days off duty.

Under the heading "gastro-enteritis" are included diarrhoea and/or vomiting. This condition tended to occur in outbreaks of two or three cases within a few days, or in larger outbreaks such as those of Nov.-Dec., 1937, and March-April, 1938, when 32 and 25 nurses respectively were affected. The nurses were scattered in different wards, suggesting that they had been infected from a common source—possibly in the home rather than in the hospital itself. (It is interesting to note that one of the nurses in the 1937 outbreak apparently introduced the infection to a children's ward, in which 7 children developed dysentery. From this nurse, and from 4 of the affected children, *Bact. sonnei* was isolated.)

The common infectious diseases (including scarlet fever, which might alternatively be classified as sore throat with rash) numbered 12 in 1936, 37 in 1937 (22 of which were rubella), and 3 in 1938. One case of diphtheria occurred in 1936 and 3 in 1937. The common infectious diseases were important on account of the number of days lost rather than of the number of attacks; during the 3 years they accounted for 4.7% of the total number of illnesses, but for 11.9% of the total sickness-days.

Injuries, including burns and scalds, amounted to 7.6% of all sicknesses and to 5.3% of all sickness-days. Whether or not they were due to hospital mishaps or accidents was not recorded, though in the few instances of lysol burns these were presumably incurred on duty.

Respiratory infection played a predominant part as a cause of the 22 "long illnesses" tabulated in Table II. Four of these were due to upper respiratory tract infections and their sequelae, two to influenza followed by pleurisy or pneumonia, and one to unresolved pneumonia. During the three years 7 of the nurses who suffered from long illnesses left the hospital; of these, 4 had developed pulmonary tuberculosis and 1 tuberculosis of the ileum. Another nurse, who suffered from pulmonary tuberculosis, returned after an absence of 11 months. The figures presented here are too few to form the basis for a discussion on the incidence of tuberculosis among nurses. A growing realization of the tuberculosis risk in hospitals has led to investigations by numerous workers, particularly in Norway and the United States. Soper and Amberson (1939) summarize the situation by stating that prevailing opinion strongly suggests that the incidence of tuberculosis is higher among student nurses than among females of similar age groups in the general population. Tuberculin tests almost without exception indicate year by year an increase of infection out of proportion to that of the general population. These authors advocate certain minimum precautions and stress the importance of case-finding among patients, for they consider that unrecognized cases of open tuberculosis are a serious menace in general hospitals.

### Standards for the Maintenance of Nurses' Health

The Ministry of Health Interdepartmental Committee on Nursing Services (Interim Report, 1939) discussed the question of the care of nurses' health and the provision of medical attention, in the form both of medical inspection and of attention during sickness. The report stated that medical inspection of entrants seemed to be general, though not universal, but that apparently in most hospitals no further inspection was made during training. It recommended the practice of thorough medical examination, with a chest radiograph, four times during the training period and again on appointment to the staff.

Pietzcker (1937) tabulates the international figures derived from her questionnaire on the subject of medical inspections, chest radiography, immunization, etc. Her figures for seven countries, including Great Britain, are shown in Table III.

At the 1937 Congress of the International Council of Nurses Lambie of New Zealand emphasized the need for standards of health and service which could be followed in every training school. The following measures which she proposed are in many ways similar to those of the numerous American Health Programmes for Nurses, of which Fuld (1937) and Davies and Frost (1940) have described examples, and to the recommendations set out more recently in this country by the King Edward's Hospital Fund for London (1943) and by Court (1943).

1. General Health Measures.—(a) Adequate living conditions, individual rooms and good recreation-rooms. (b) Three balanced and regular meals each day or night. (c) A carefully sidered programme of work, recreation, outdoor exercise, and sleep. (d) Regular leave and off-duty time.

2. Physical Examinations, etc.—(a) Medical and dental examinations on entry. (b) Radiograph of chest on entry. (c) Diagnostic skin tests, and immunization against diphtheria and enteric fevers. (In some hospitals immunization against smallpox and scarlet fever is also the rule.) (d) Repetition of medical and dental examination, and of chest radiograph, at intervals of 6 to 12 months. (e) Repetition of tuberculin test six-monthly in negative reactors. (f) Monthly weight chart for each nurse. (g) Correction of physical defects, if any.

3. Care of Sick Nurses.—(a) Opportunity to report sick at any time without fear of rebuke. (b) Encouragement to report minor disturbances of health immediately. (c) Direct access to medical advice. (d) A properly equipped minor ailments surgery. (e) Adequate sick-room accommodation.

4. Aseptic nursing procedures which should be carried out in the light of modern bacteriological information and which should be kept up to date with new advances.

5. Education of the nurses as to the value of a health programme, and the development of their interest in preventive medicine and "positive health."

6. Research as to the effects of hospital service upon the health of nurses, as shown by the incidence, nature, and predisposing causes of their ailments.

TABLE III.—Figures regarding Medical Examination, Immunization, etc., of Nurses in Various Countries. (From Pietzcker, 1937.)

Country	G.B.	U.S.A.	Canada	New Zealand	France	Norway	Rumania
No. of hospitals taking part	20	27	38	26	31	9	4

Percentage of hospitals checking weight of nursing students monthly or quarterly	5	85	82	100	77	22	100

### Discussion

While there has been considerable interest in the occurrence and prevention of tuberculosis among nurses, little information is available concerning the nature and incidence of other illnesses. Certain American workers have found that student nurses are more subject to illness than college girls; and Diehl (1935) observed that this higher morbidity rate was mainly due to cutaneous and upper respiratory tract infections. This fact he attributed to the nurses' occupational hazards; and data collected by the National League of Nursing Education in the United States confirm his findings. Its survey indicated that student nurses on their clinical course had a higher sickness rate than those who, on their preclinical course, were not in contact with ward work; and, further, that among nurses undertaking duties where exposure to infectious diseases was greatest—as on the paediatric and communicable diseases service—sickness rates were higher than elsewhere.

The figures presented here from the records of University College Hospital for 1936 to 1938 confirm those of Branson

of St. Bartholomew's Hospital for an earlier date, in that nearly 60% of all attacks of sickness were due to pyogenic and respiratory tract infections. In both series sepsis took first place, both for number of attacks and for number of days of sickness. In this they differed from the figures of Rhoads and Afremow and of Court, who found that respiratory tract infections were the main cause of absence through sickness. The high rate of whitlows among nurses is worth mentioning. Branson found that this condition was responsible for a considerable majority of the cases of sepsis; and at University College Hospital it accounted for 11.6% of all attacks of illness and of all days lost through sickness. Spooner (1941) observed that septic fingers and hands among the nurses of a surgical ward seriously interfered with the work; and the present investigation was, in fact, encouraged by the frequency of whitlows among the nurses of a war-wounds ward.

The many cross-infection studies of the last few years have shown that nurses not infrequently acquire infections from their patients. Okell and Elliott (1936), for example, working in an ear-nose-and-throat hospital, found that nurses were implicated in nearly half the ward outbreaks of haemolytic streptococcal infection, and that the nurses' infections were associated with the same types of haemolytic streptococci as those which cross-infected the patients. While aseptic techniques have been regarded mainly from the angle of protecting the patient from the nurse, their function is dual: they should also serve to protect the nurse from the patient. This aspect of nursing technique has been stressed more in sanatoria for tuberculosis than in other types of hospital.

The present scanty information regarding the predisposing causes of the illnesses to which nurses are prone indicates that there is scope for further investigation on the matter. That infection rates may vary considerably from one group of nurses to another within the same hospital is to be seen from the figures tabulated by Court. He found, for example, that respiratory infections during 1942 varied from a 23% incidence among student nurses to a 68% incidence among assistant nurses, and that, while septic fingers developed among 13% of the latter group, they occurred among only 1.6% of the trained staff. It would be interesting to know if the operating-theatre staff, who are protected by masking, gowning, and a meticulous aseptic technique, have a more favourable health record than nurses on ward duty.

To gain more knowledge of nurses' sicknesses and their causes careful recording and analysis would be required with regard to age, years of service, ward assignment, nature of duties, and day and night schedule; and also to the clinical character and duration of each sickness, and the length of sick-leave. In addition, accurate records of the number of nurses at risk in each circumstance would be needed for the determination of the comparative sickness rates. An investigation of this kind should throw light on the reasons for the generally recognized high rate of skin and respiratory tract infections among nurses; and the information gained would be a necessary preliminary to the introduction of special measures for their prevention.

### Summary

An analysis is made of the nature and incidence of sickness among the nursing personnel at University College Hospital during the three years 1936 to 1938. More recent figures could not be used because of the various administrative changes brought about by the war.

Among the causes of sickness and days lost through sickness, pyogenic infection took first place, closely followed by upper respiratory tract infection. The two infections taken together accounted for nearly 60% of all sicknesses.

Whitlows were responsible for 40% of the pyogenic infections, and for 11.6% of all sicknesses and of all days lost.

Common infectious diseases were important for the number of days lost rather than for the number of nurses involved.

Of 22 long illnesses (more than 100 days), 6 were due to tuberculosis (5 pulmonary and 1 of the ileum); 7 other long illnesses were caused by complications resulting from respiratory infection.

The importance of nurses' sickness in relation to cross-infection problems is discussed, and stress is put upon the need to investigate further the predisposing causes of infection among nurses, as a preliminary to prevention.

I am indebted to the Matron, Assistant Matron, and Home Sister of University College Hospital for their assistance with this work to the Nursing Committee of the hospital for permission to publish the figures; to Prof. A. A. Miles for his help and advice; and to the Medical Research Council for a personal grant.

## CYCLOPROPANE FOR DENTAL SURGERY IN CHILDREN\*

BY

K. B. PINSON, M.B., Ch.B., M.R.C.S., D.A.  
*Anaesthetist to the Manchester Royal Infirmary*

School-children, a few younger pre-school children, and expectant and nursing mothers attend the Stretford Borough clinics for dental treatment. Roughly 65% of those offered treatment accept it. It being desirable that this percentage should rise, any necessary anaesthesia should be as pleasant and as free from distress as possible. I am indebted to Mr. Ronald Bradbury, L.D.S., now serving as a dental surgeon in the Army, to Miss A. M. Paterson, L.D.S., and to Miss P. E. Pendlebury, L.D.S., for their co-operation. A short account, by Mr. Bradbury and myself, of the first 75 cases with cyclopropane appeared in the *British Dental Journal* on June 3, 1943, and these cases are included in this series because, although the method was afterwards altered somewhat, the essence of it remained the same. Follow-up observation was impracticable, and so of only a small proportion is there any information as to progress at home.

The method is simple, and so is the apparatus required. This simplicity is made possible by the slowness with which CO<sub>2</sub> accumulates in a breathing-bag in the case of children, so that its removal by soda-lime absorption, which generally is a *sine qua non* in cyclopropane anaesthesia, is not necessary. For older children and longer operations than the extraction of teeth the method is thus unsuitable. The technique is almost rule of thumb. Cyclopropane is a most potent gas, but if given by an anaesthetist of experience there appears to be only one risk which he will have to bear in mind. As will be seen, its origin is salivation. Other anxieties are conspicuous by their absence. In roughly a quarter of these cases the administration was by students.

Cyclopropane recommends itself for this work because it combines the following desirable qualities, variously present in other agents: an attractive induction, rapid and smooth; ample time and ample depth of anaesthesia; freedom from untoward effects such as blueness, breath-holding, movement, spasm, difficulty of administration owing to mouth-breathing or attainment of a correct mixture or insufficiency. It also has one advantage over all others—the degree of jaw relaxation. Early relaxation of muscles is a characteristic of cyclopropane, but of the jaw muscles it is a peculiarity. As a rule the mouth gag is not used—a benefit by no means trivial. There are disadvantages, however, as will be seen, and they appear in the after-effects—chiefly sickness. Comparison has to be made with other satisfactory systems—with vinesthene, and with continuous nitrous oxide with oxygen, trilene, or vinesthene. There are cases for which cyclopropane is preferable to any of these.

\* A survey of the first 500 consecutive cases at the Borough of Stretford School Dental Clinic.

## Description of Apparatus

The apparatus used comprises: (1) a holder for the cyclopropane cylinder; (2) a measuring device; and (3) a breathing-bag, connected to a nose-cap by as short a length as possible of wide-bore tubing. There are no valves. For (1) any convenient stand or place to fix the cylinder yoke is suitable: we have a separate disused  $N_2O$  apparatus. (2) The very satisfactory measuring device we use consists of a small rubber bag, fixed adjacent to the cylinder, which holds rather over a pint, and which is filled direct from it. Between this and the rebreathing-bag is a Higginson syringe, by which its contents are delivered as desired into the breathing-bag. An oxygen cylinder with a fine adjustment or a reducing valve is also connected to the breathing-bag. Three of the small bagfuls is the usual consumption of cyclopropane. (3) The breathing-bag is of the common two-gallon capacity, and its mount is screwed to the chair as near to the patient's head as possible. About a foot of flexible wide-bore tubing connects it direct to the nose-cap.

## Mode of Use

This simple apparatus is very straightforward in use. The child is seated in the chair and the nose-cap quietly applied. As he is engaged in conversation the breathing-bag becomes one-third filled with oxygen. He is now told to keep his mouth closed for a minute, as it is easier to breathe through the nose. This he finds unobjectionable, because there is only oxygen in the bag. The measuring-bag is now filled, and the contents pumped, slowly at first, into the breathing-bag by squeezing the ball of the syringe, preferably during expiration. The method is a closed one, so that mouth-breathing is to be avoided almost from the start.

Cyclopropane is easy to inhale, is not resented, and rarely gives rise to any movement, much less to struggling or spasm. Sleep comes quietly and quickly, so the second and third pints follow the first without pause, and can be pumped more rapidly as the child becomes unconscious. Perhaps half the contents of the bag will be oxygen, and more can be added, although as a rule little is lost (through mouth-breathing) during the extractions. The colour remains perfectly good. Work is begun as soon as the patient is under and the jaw relaxed. No change is made; the nasal breathing continues, and the effect of gradual accumulation of  $CO_2$  is offset by respiratory depression.

Table showing Analysis of First 500 Cases

A. Number	B. Dangers encountered	C. Difficult Cases (or not Completely Satisfactory)	D. Salivation	E. Sick	Felt Sick
500 cases, 1 to 91 and No. 109: face-piece over mouth and nose. Remainder by method described	1 (No. 43)	25 (9 due to salivation)	37	In chair, 20; in recovery room, 84. (27%) (6 were noted as having had food)	7
F. III After-effects (Other than Vomiting and Reports from Home)	G. Serious After-effects	H. Reports from Home	I. Ages	J. Special Cases	
18	None	(Very incomplete) 3 quite well a ter 4 sick or poorly 5 at school next day 1 off school 5 days 1 .. 3 weeks	1 to 5 (75) 6 to 8 (196) 9 to 11 (126) Over 11 (78) Not noted (25)	3	

K. Consumption and Cost.—Gallons, 120; cases, 299; gal./case, 0.42; pints/case, 3.3; case/gal., 2.4; cost per case, at 2s. 6d. per gal., 1s. 0½d.

Temporary or partial obstruction does not matter, as oxygenation has been perfect; neither does it result in heaving efforts to breathe. Quietude and jaw relaxation are, in fact, noteworthy. With big children,  $CO_2$  begins to mount after a minute or two and causes deeper breathing, and consequently mouth-breathing and loss of gases from the bag. On only a few occasions, however, have more  $O_2$  and cyclopropane been added.

At the end of the extractions the nose-cap is removed. Colour, breathing, and condition alike are good, and recovery of consciousness takes only a minute or so, though it is not

so quickly complete as in other eligible methods, and it has been taken the child will vomit very soon. The child does not usually walk from the room, but are carried. They are able, however, to sit up over a basin and wash their mouths out with water.

From the point of view of the dentist it is perhaps the most satisfactory method of all for those cases to which it is suited—that is, to children up to 12, or for work not taking more than three minutes or so. Also, from the point of view of the administrator it is very safe, and is free from troubles and anxieties. From that of the patient, however, while induction is equally as acceptable as that of other means—perhaps more acceptable—the after-effects sometimes fall short of what is desirable.

## Remarks

(B) The patients sometimes secrete profusely, and the respiration is always rather depressed; if saliva is allowed to trickle down the larynx, that and the consequent laryngeal spasm, and the enfeebled breathing effort, may bring about asphyxia. The treatment, apart from prevention, would be to invert the child (so as to empty out the saliva) and blow into the lungs a little oxygen or air—e.g., by mouth-to-mouth insufflation. This procedure is well known to anaesthetists, is simple, is quite efficacious, and should not be delayed. It would be well if it were better known to the occasional anaesthetist. Such was the case with No. 43. More cyclopropane was given immediately afterwards and the extractions done. This patient slept afterwards for a while, but was not sick.

(C) Apart from those cases in which salivation caused some obstruction or blueness, three gave incompletely satisfactory results owing to mouth-breathing during induction. Two coughed, one of whom—6 years old and attending the open-air school on account of his chest—coughed almost incessantly before, during, and after induction. He became blue at one time. In seven the anaesthesia, though sufficient, was poor. Two were restless or struggled for a few moments, and in three the jaw was tight. One was a poor colour and one was very sick. In no case was the work left uncompleted, and in none was any pain experienced. It should be noted that some of the cases were managed by students.

(D) Regarding salivation, a little experience overcomes any difficulty.

(E) Cases of vomiting were carefully noted, though doubtless some were missed. Generally it was soon over.

(F) Ill after-effects were of a minor character. The patients so affected include five who were irritable or rough for a short time before quite coming round, four who were drowsy, four who cried, two who were a bad colour or pale, two who felt poorly, one who was faint, and one who coughed a great deal. One of these stayed two hours before going home; the rest soon recovered. One had had no ill effects after cyclopropane three weeks before.

(H) With regard to school attendance afterwards, there was always a proportion, after any anaesthetic, who did not go back for a few days.

(J) Under this head, one was an imbecile girl aged 10 who took the anaesthetic without difficulty and had no ill effects. Another was a bad asthmatic—a small boy attending the open-air school. He was a mouth-breather, was not well under, and was off school for five days afterwards. Cyclopropane was chosen as being most suitable for him. The third was the boy of 6 who coughed almost without stopping, and so was difficult.

It is not easy to convey an impression of how the administration goes or how the children react. In general, a cap over the nose is less alarming than a face-piece which covers both nose and mouth. In either case we do not often have any trouble, and crying is uncommon. With few exceptions the children behave very well indeed. Cyclopropane induction is notably smooth, and a sleepy feeling overcomes them very soon. Being unhampered by valves, etc., and the fact that they can talk and that there is no hurry, help them to be confident. The method is thus rather easier to manage than others. Of preparation beforehand there is none beyond abstinence from food. We do not give atropine.

## Summary

A description is given of a new method of administering cyclopropane for dental extractions in children and of the apparatus employed. A detailed review of the first 500 cases is made. The conclusion is advanced that it is a simple and safe method, advantageous to the dentist and giving full satisfaction in all respects except for undesirable minor after-effects, and that the incidence of vomiting is rather high. The cost is a little more, but still is comparable with that of other systems.

## EARLY SECONDARY REPAIR OF COMPLETE TEARS

BY

PERCY MALPAS, F.R.C.S., F.R.C.O.G.

*Honorary Surgeon, The Women's and Maternity Hospitals,  
Liverpool*

There is still a general lack of agreement as to when complete tears that have broken down after immediate suture should be repaired again. In most of the textbooks the point is evaded by the statement that when a primary repair is done within 24 hours of delivery a successful result is usually obtained. While there is no doubt that this is true if the repair has been carefully done under good operating conditions, many do break down within the fortnight under the conditions of general practice. This is shown by the frequency with which patients with complete tears come up for operation months or even years after delivery. For instance, during the last five years 40 of such cases have been operated upon in the Women's Hospital, Liverpool. In each of these an immediate repair had been unsuccessful; healing by second intention had been allowed to take place and the necessary repair deferred until the patient was driven to hospital by the inconvenience of the incontinence or freed from the responsibility of the care of the baby to have time for the operation. Most of these late operations would have been avoided by the procedure here suggested.

The recommendation given by most authorities is that a secondary repair is best deferred for at least three months after delivery, until the parts are clean and involution has taken place. Against such a course there are, however, two very real objections. In the first place, the woman is left most uncomfortable at a time when she needs all her energy. In the second place, involution, though bringing certain advantages, entails the great disadvantage that both the fornix muscle and the mucous surfaces retract and undergo permanent shortening, with the result that undue tension is needed to reapproximate the tissues. The reason usually given for deferring the re-suture is that the raw surfaces are granulating and infected, and union therefore is not likely to be obtained. Smellie (1758) describes one such case:

"I was called by a midwife to a woman on the fifteenth day. The Perinaeum, Vagina and Rectum were tore into one about the length of two inches which prevented the retention of the faeces. The edges of the lacerated parts were beginning to skin over. I attempted with scissors to pare the edges, as in the hair lip; but could not possibly hold the parts so as to effect this purpose. I then armed a lancet, and with the point scarified them and with great difficulty made two stitches through the Vagina and Rectum and two in the Perinaeum; but in two days this brought on a large inflammation and the stitches all tore out. The parts digested and skinned over but did not cement or join together; however they contracted in such a manner that in three months after she could retain her excrements."

There is no doubt that these cases do look at first sight most unsuitable for early repair. The raw surfaces are covered with granulations, the tissues are friable so that the sutures tend to cut through, and the whole area is heavily contaminated with faeces.

On the other hand, and despite these objections, early re-suture is a practicable procedure; in the six cases I have seen during the past two years it has been employed, and proved a success. The operative difficulties are easily offset by the advantages gained by doing the operation at once.

Four of the patients had been delivered with forceps by their own doctors in nursing homes. The other two had been delivered with forceps in hospital by residents. In every case primary repair had been undertaken at once but had broken down within a week of delivery—in five of the cases completely, and in one partially so as to leave a recto-vaginal fistula. Two of the cases were pyrexial owing to a uterine infection.

In each case a secondary repair was undertaken as soon as it could be arranged—one 7 days after delivery, one 10 days, one 13 days, one 15 days, one 3 weeks, and one 4 weeks. In the two pyrexial cases operation was delayed

until the acute uterine infection had subsided. During the few days before operation the raw surfaces were kept as clean as possible, but otherwise no special treatment was given. Five of the repairs were done personally; the sixth done by Miss M. Mayeur, F.R.C.S., on one of the hospital cases.

Every case healed well and gave no more trouble than the usual complete-tear repair. Complete control and healing were established within two weeks of undertaking the repair. The convalescence of one of the pyrexial cases was complicated by repeated secondary haemorrhages from the uterus. Despite the patient's poor general condition and the need to treat the haemorrhage by firm vaginal packing, the perineum healed normally.

The operation calls for no special technique, although good operative conditions are essential. It is neither possible nor desirable to coapt the skin of the perineum very closely, with the result that the appearance of the perineum at the close of the operation is not artistic. No special attempt need be made to clear the granulations from the raw surfaces, but most are in fact cleared away by the manipulations employed in defining the rectal mucosal edges and the ends of the anal sphincter. Great care must be taken to free the rectal and anal mucosal flaps completely from the underlying tissues. This should be done so freely that the two edges of the mucosa fall into apposition even before the sutures are inserted. As in all these repairs, special care must be taken to close the upper end of the rectal tear. After dealing with the mucosa the perineal body is repaired and the sphincter restored in the usual way. Little or no trimming should be done, even at the expense of leaving an irregular suture line. Interrupted stitches should be used throughout—No. 2 plain catgut for the rectum and deep tissues, silkworm-gut for the perineal skin. A short split-tube rubber drain is an advantage, left in the recto-vaginal space and brought out through the centre of the perineum, and remaining in position for two or three days.

While the object of this note is to draw attention to the possibility of early re-suture, reference may properly be made to the likely causes of the failure of the initial repair. The immediate technical fault in most of these cases is certainly the failure to suture the upper end of the mucosal tear. When the repair breaks down the disruption usually takes place from above downwards; first a recto-vaginal fistula appears, and then the whole wound "gives," the skin perineum last. There is no doubt that this primary failure in technique is due to the difficulties caused by poor operating conditions, uterine haemorrhage obscuring the field, and perhaps the strain of the antecedent forceps delivery. Many, if not most, of the failures would be avoided if it were the rule to defer the primary repair of complete tears for 12 to 24 hours after delivery, until better conditions and perhaps better assistance can be obtained.

## Medical Memoranda

### A Case of Compressed-air Illness

Compressed-air illness, more commonly known as "bends," is a disease familiar to all divers, airmen, and medical officers associated with this work. The present great increase in altitude flying and underwater work has revived interest in this formerly limited industrial disease. Briefly, it has its origin in a dangerous and excessive release of pressure of air, causing the tissues to become supersaturated with nitrogen, bubble formation to occur. These bubbles may appear in circulating blood and cause pulmonary embolism; in the vessels of joints or muscles, causing the most common syndrome of "diver's bends"; or in the central nervous system, causing coma, confusion, cerebral palsies, and various types of myelitis with paralysis of limbs and incontinence. Symptoms vary enormously, depending on the site of formation or lodgment of the bubble. As fat dissolves far more nitrogen than water, the occurrence of bubbles in the central nervous system is not

surprising event. Itching of the skin, which is often encountered after decompression, is also ascribed to minute bubbles in the subcutaneous fat. Skin rashes occur, and may be due to minute emboli in the cutaneous vessels.

Ordinary "bends" are severe boring pains in the vicinity of the large joints and the small joints of the hands and feet, particularly in persons suffering from old trauma or disease. This is by far the most common form of the disease, and, although causing great pain, it in no way endangers life. These pains have been ascribed to bubble formation in the ligamentary and tendinous insertions, embolism in the vascular bed involved in infective osteomyelitis, or bubble formation in the nerve trunks or central nervous system, causing referred pain. Itching of the skin may also be due to more distant neurological events.

At present, therefore, various paralyses are known to be due to interference with the motor centres or motor path, but sensory disturbances of nervous origin, apart from blindness and deafness, are not encountered in the literature. The following case is thus of great interest.

#### CASE RECORD

A petty officer of the Royal Navy, aged 38, weight 174 lb., of lean athletic build, acted as attendant to an experimental subject at a pressure of 40 ft. of sea-water (18 lb.) for two hours. He was breathing air the whole time, and wore no respiratory apparatus of any kind. He "surfaced" (returned to atmospheric pressure) in one minute, no stops being necessary according to the Admiralty decompression table (after the late Prof. J. S. Haldane).

Five minutes after "surfacing" a pain developed in the top left premolar. It was a severe pain with an unusual emotional content. This was at first thought to be due to a sealed cavity under a stopping of the tooth or to an abscess cavity at the root. The subject was immediately recompressed to 18 ft. of sea-water, when instant relief of pain occurred. He was returned to atmospheric pressure in 30 minutes. After this, pain, although still present, was less severe. He then went to lunch, during which the pain increased in severity and anaesthesia of the upper left gum and teeth developed, the posterior tooth and gum being first involved, and anaesthesia spreading forward and ceasing at the midline. The pain remained localized to the premolar. It was now apparent that a bubble had formed, involving the second branch of the trigeminal nerve. Appropriate subcutaneous anaesthesia was not present.

Immediate recompression to 12 lb. was carried out, and relief was at once obtained. Decompression at the rate of 8 minutes per lb. was instituted. At 5 lb. the pain in the tooth returned, but was not severe, and decompression continued. At 3 1/4 lb. anaesthesia returned, followed by a most agonizing neuralgia in the whole of the distribution of the second branch of the trigeminal nerve. The patient sweated, bit on his handkerchief, and was writhing with pain. The tender points of Vallex (temporo-malar and infraorbital) were present. Immediate recompression to 13 lb. was carried out, with complete disappearance of symptoms. Decompression at a slower rate of 12 minutes per lb. was then performed, and the patient "surfaced" symptomless, and has remained so ever since. Tenderness had also completely disappeared.

#### COMMENT

There is no previous history of trigeminal neuralgia, ear, nose, or throat infection, or dental caries. He suffers sharp dental pain in this particular premolar if it is exposed to extremes of temperature, and there is slight enamel erosion at the base near the gum. Recent dental examination revealed no other disease.

The points of interest in this case are: (1) The occurrence of bubble formation after exposure to such shallow depth. (2) The occurrence of bubble formation in a diver who has been exposed to varying degrees of pressure several times a week over a period of a year and a half without symptoms. In this time it had been ascertained that he was apparently extremely resistant to "bends," but the long period of pressure work may well be a contributory factor to the attack described. This case is a good example of how compressed-air illness may occur when and where it is least expected. (3) The occurrence of bubble formation definitely involving a sensory nerve. (4) The attack of tic douloureux, involving the whole distribution of the second branch, suggests very strongly the involvement of the Gasserian ganglion, and adds weight to the previously tentative opinion that many cases of "bends" in joints may be due to bubble formation in the sensory ganglia. The occurrence of anaesthesia in a limited zone in association with severe neuralgia is an interesting problem for neurologists. (5) Hard work of any group of muscles, at pressure, is well known to predispose to "bends" in that region, and in this case the attendant sang loudly and uproariously for over an hour, for the supposed edification of the subject. Whether or not this explains the site of the disease is problematical, but this may be the first reported case of "operative bends."

Medical Officer in Charge of Admiralty  
Experimental Diving Unit.

## Reviews

### PICTORIAL AIDS TO ANATOMY

*Illustrations of Regional Anatomy.* By E. B. Jamieson, M.D. Fifth Edition. Section I: Central Nervous System (50 plates). Section II: Head and Neck (64 plates). Section III: Abdomen (44 plates). Section IV: Pelvis (38 plates). Section V: Thorax (32 plates). Section VI: Upper Limb (42 plates). Section VII: Lower Limb (52 plates). (Bound volume 75s. plus 10d. postage.) Edinburgh: E and S Livingstone, 1944.

That the fifth edition of Dr. E. B. Jamieson's *Illustrations of Regional Anatomy* should have appeared during wartime so soon after its predecessor is undoubted evidence of its popularity, and the care which has been taken both by the author and by the printers to obtain clarity and accuracy in the figures and pointer legends is manifest to anyone who has to deal with this kind of work. In these days, when it is of the utmost importance that time should not be wasted in unnecessary efforts, and that the eye-strain incurred in the identification of particular reference letters in a legend should be avoided, the gain arising from the use of clear pointer legends is obvious. Although from the standpoint of operative surgery nothing can replace the basic knowledge of anatomy gained in the dissecting and post-mortem rooms, illustrations such as those in the work we are considering are manifestly of great value to the student in a rapid revision of the whole field of anatomy just before an examination, and these clear-cut coloured figures admirably fulfil this purpose. There are, however, a few points which call for comment: thus in Plate 271 (Lower Limb) the pointer, which should indicate the groove behind the fossa for the attachment of the tendon of the popliteus muscle, is directed to the flat surface on the lateral condyle of the femur, immediately in front of the fossa, and in the illustration there is no indication of the groove itself. A note of warning is also necessary in order to counteract false impressions which may arise from a too general simplification of the picture by omission in certain cases of the shading which is required to indicate a difference in plane between the two surfaces, more especially in the representation of convex or concave surfaces and parts which, owing to the obliquity of the object depicted in relation to the surface of the paper, it is necessary to distinguish by variations in tone between a more distant and a nearer part. An example of this is seen in the postero-medial view of the ankle (Lower Limb, Plate 38), in which the more distant first metatarsal base and the medial cuneiform appear to be on the same plane as the nearer posterior surface of the calcaneus, the impression given being heightened by the sharp contrast between the unshaded dead white of the base of the first metatarsal and the black background. Apart from these purely technical considerations, however, the main purpose of the work, issued as it is in separate sections of handy size, is well fulfilled.

### MEDICAL PARASITOLOGY

*A Manual of Medical Parasitology.* By Clav G. Huff, Professor of Parasitology in the University of Chicago. (Pp. 88; illustrated, 9s.) Chicago: University of Chicago Press; London: Cambridge University Press.

This is a laboratory guide to medical parasitology intended for use in practical classes. It describes with illustrations the life-history of the various parasites and insects involved in the production of tropical diseases. The system of classification in the three main groups under protozoology, helminthology, and entomology is dealt with in sufficient detail for the student's guidance. There is a final chapter on staining methods and other procedures to be adopted for the discovery of parasites and the diagnosis of infections. The illustrations on the whole are quite good, though one wonders why the cyst wall of *Entamoeba histolytica* and *E. coli* have such irregular outlines while that of *Iodamoeba bütschlii* (referred to as *I. williamsi*) is not visible at all. The same remark applies to the cyst wall of *E. nana*.

There is a coloured plate of malarial parasites. This is excellent, save for the Schueffner dots, which have an unfamiliar appearance. It is perhaps surprising that a plate illustrating the haemoflagellates is conspicuous by its absence. Apart from these details the book will serve a useful purpose, and will be an excellent guide to have beside one when working with the microscope in the laboratory.

## OTO-RHINO-LARYNGOLOGY

*Office Treatment of the Nose, Throat and Ear.* By Abraham R. Hollender, M.Sc., M.D., F.A.C.S. (Pp. 480; illustrated. \$5.00 post paid.) Chicago: The Year Book Publishers, Inc. 1944.

*The 1943 Year Book of the Eye, Ear, Nose and Throat.* The Eye: Louis Botham, M.D. The Ear, Nose and Throat, by Samuel J. Crowe, M.D. With the collaboration of Elmer W. Hagens, M.D. (Pp. 580; illustrated. \$3.00.) Chicago: The Year Book Publishers.

The author of *Office Treatment of the Nose, Throat and Ear* has devised a highly artificial classification of diseases into two kinds, of which the nature is evident from the title of his book. He has, however, succeeded very well in giving a practical account of the treatment which may be employed without confining the patient to bed immediately afterwards, but it is not surprising that on some occasions the dividing line becomes rather blurred. Naturally the major operations do not come under review, but he says, for example: "To-day it would sound like anachronism to speak of tonsillectomy as an office procedure, yet one may visualize it as such when the usual hospital facilities are not available." It is the custom in the U.S.A. to carry out much more treatment in the office, which is correspondingly equipped, than in the simpler consulting-rooms and out-patient departments of Great Britain. Making allowance for this it must be recognized that he describes much that it would not be wise to do in an ordinary consulting-room. There is great value in the emphasis this book lays on the large amount of treatment which can usefully be given by prescriptions, injections, physical therapy of various sorts, and very minor surgical manipulations without resort to the major surgery which is apt to fascinate the exponents of what is largely a surgical specialty. Other authors are quoted freely, especially on the endocrine and nutritional disorders to which Dr. Hollender attaches great importance. Some of the treatment is surely out of date, as exemplified by the picture of a lady wearing a dog collar to which two electrodes are attached for the cure of hysterical aphonia. This malady can be treated in the office without this apparatus, but generally Dr. Hollender is a safe guide, and he shows that more can be done by medical and minor procedures than is always appreciated.

War conditions have imposed slight alterations in the production of the *Year Book of the Eye, Ear, Nose and Throat*, but these are scarcely perceptible without direct comparison with a previous number. Except for a slight fall in the sharpness of the illustrations the quality of the contents remains unimpaired, and there will be found admirable summaries of current literature with the usual illuminating comments by the editors, who all continue their excellent work. The need for these summaries is greater than ever during the present period of difficulty in the distribution of scientific literature. They are the more valuable because the editors, who know the literature of their subjects besides being men of great practical experience, are able in a few lines to indicate the value of a paper, whether it embodies a valuable idea, whether it is just ephemeral, whether it reviews something that has already been tried and found wanting, or whether it contains some fallacious notion. Chemotherapy finds a prominent place in both the main sections. Both penicillin and the sulphonamides are the subject of much observation and experimentation. There is a curious misprint in a paper on glossopharyngeal neuralgia: the digastric is called the "digestive" muscle, but this is only noticeable on account of the laudable rarity of such errors.

## Notes on Books

*Spectrophotometry in Medicine*, by L. HEILMEYER, translated by A. Jordan and T. L. Tappell, is published in London at 30s. by Adam Hilger. The content of this monograph is indicated by the first sentence of the author's foreword: "The present monograph has been evoked by the need for an exact physical definition of the colours of body fluids and body pigments." The translators have supplemented the original (1932) description of instruments with an account of those now used in this country, and the original German symbols have been replaced by others more commonly used here. Starting with the theory of absorption spectrophotometry, the author goes on to describe selected apparatus and methods in some detail. The bulk of the book is devoted to detailed description of the absorption curves of whole blood, haemoglobin and its derivatives

and breakdown products, serum, urine, bile, ascitic fluid, cerebrospinal fluid. Since under these headings both normal and pathological fluids are considered, as well as pigments of urine due to drugs, the book provides a comprehensive survey of the curves of all pigments found in association with the human body. It should be of great value to those with the facilities for carrying out spectrophotometric analyses on clinical material. It is unfortunate that more than ten years have elapsed before this useful translation has become available.

*Dental Histology*, by JAMES AITCHISON and JOHN S. DICK (J. & Balc Medical Publications; 18s.), is a small book compiled from lecture notes and will be most useful to the student when making his own slides and during revision for examinations. There are some excellent photomicrographs, but these would be of more guidance if they could be produced in colour and augmented by diagrams illustrating the structure of the dental tissues.

## Preparations and Appliances

## THE ROCKER WALKING IRON

Capt. G. E. FOSTER, M.D., C.M.(McGill), graded surgeon R.A.M.C., writes from the British Military Hospital, Bermuda

A rocker walking iron is described by Major T. T. in the *British Medical Journal* (July 3, 1943). I have used, every satisfaction, a different type, as described below:

## Description of Apparatus

- (1) An iron strap, 30 in. x 1 in. x 1/8 in. to 3/16 in., is bent in the shape shown in Fig. 1. Heating facilitates this, but is not essential.
- (2) The rocker surface is covered to prevent slipping. A piece of old bicycle tyre is suitable, and may be laced on. Alternatively, a leather strap may be riveted on.
- (3) An unpadded plaster cast is applied in the usual way. The posterior slab should be substantial (15 to 18 layers).
- (4) When the cast has hardened, a single plaster bandage suffices to secure the iron (Fig. 2A).
- (5) The well foot should be fitted with a built-up wooden sole screwed on to a canvas shoe in order to equalize the leg length (Figs. 2B and 3).

FIG. 1

FIG. 2

FIG. 3

Fig. 1.—Rocker iron fitted with rubber tread (from old bicycle tyre).

Fig. 2.—(A) Rocker iron incorporated in plaster cast. (B) Built-up wooden sole attached to canvas shoe on well foot.

Fig. 3.—Wooden sole, top and side view.

## Advantages

- (1) The rocker, as stated by Major Stamm, unquestionably "ensures a natural heel-toe action in walking."
- (2) The type I describe needs no bolting to a sole plate, and the long upright part distributes the weight over more of the cast as well as stabilizing the rocker. The appliance remains firm and secure after several weeks' service, and the same iron may be used repeatedly.
- (3) The built-up sole on the well foot greatly facilitates walking.

This particular rocker iron has been used in the U.S.A. and Canada for several years. The type of built-up sole I mention is standard in some U.S. service hospitals.

My thanks are due to Major S. G. M. Lynch, R.A.M.C., Senior Medical Officer, Bermuda Command, for permission to forward this paper.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 29 1944

## MANAGEMENT OF THE ACUTE HEAD INJURY

This war has so far yielded a much higher proportion of closed head injuries<sup>1</sup> than was expected, and as a consequence emphasis has been placed on the medical aspects of their management. In the field the neurosurgeon is faced with the immediate repair of soft tissue, and a series of papers by Ascroft,<sup>1</sup> Eden,<sup>2</sup> Shorstein,<sup>3</sup> Cairns,<sup>4</sup> and others have shown close agreement in the methods they have adopted. The broad principles observed by them have been to clean up the surface wounds with the most rigorous aseptic methods available, to explore for fractures, to remove all dead tissue, foreign bodies, and loose bone down to the dura mater, but below that protective membrane to exercise a healthy regard for the reparative properties of brain tissue. Ascroft<sup>1</sup> urges that an apparently intact dura should be preserved, but that the best results are obtained in penetrating injuries by sucking out necrotic brain tissue, which comes away with ease, leaving *in situ* any foreign bodies the removal of which might cause unnecessary damage to the brain. He advises a light application of a sulphonamide powder, leaving the dura open to drain into the surface wound, which is in turn drained in the ordinary way.

During the last war Cushing<sup>5</sup> said that "every scalp wound, no matter how trifling, is a potential penetrating wound of the skull," and McKissock and Brownscombe<sup>6</sup> echoed this when they showed that an apparently trivial head injury may soon cease to be trivial if great surgical care is not taken from the beginning. When all the immediate steps have been taken there is a period of anxious watching, especially if the patient is in coma, and it is then that the medical aspect of the injury becomes as much a concern of the surgeon as of the neurologist. As most of the patients with closed head injuries have wounds of the scalp, or elsewhere, they tend to find themselves, when they recover consciousness, in a surgical ward, and a surgeon has to be responsible for their medical management. Jefferson<sup>7</sup> has shown that if a head injury is fatal death usually occurs in the first day or so, for it is most often the result of extensive laceration, involving the brain stem, the symptoms of which have been described by Denny-Brown.<sup>8</sup> There is unfortunately little that can be done for the patient dying from serious damage to basal structures, but there is certainly much that should not be done. The old idea that the effects of a head injury depended upon general oedema of the brain has not survived the experience of the past five years, but, on the contrary,

Denny-Brown and his colleagues<sup>9, 10</sup> have shown that the changes are instantaneous, and are a direct result of the mechanical commotion which the injury produced. The ancient title "*commotio cerebri*" is in fact an accurate description of the physical changes which take place, although the minute nature of these changes—whether in the neurone, blocking at the synapse, or interruption of fibre conduction—is not known. Holburn<sup>11</sup> has recently shown by physical models the nature of the stresses and shears which contribute to the total commotion. It seems that unconsciousness in the subject of a head injury is the result of *commotio cerebri*, or concussion, and that cerebral laceration, haemorrhage, or local oedema are epiphenomena. Concussion begins with a total reflex paralysis, as Denny-Brown has shown, and the severity of the laceration or haemorrhage is likely to be related to the severity of the concussion, but it is because the relation is not close that there is so much variability in the pattern of head injuries. The picture of concussion, with unconsciousness, flaccidity, and bradycardia, is complicated by signs of the local lesion, and it is the physician's main function at this stage to watch the patient for changes which indicate progression of the overlying complications of haemorrhage, whether intra- or extra-cerebral, and later of infection or oedema. It is now that watchful inactivity may be commendable and that active interference may relieve the doctor more than it does the patient.

Symonds and Russell<sup>12</sup> have shown that the results of conservative treatment of acute head injuries may be excellent, and that the kind of man who is injured is about as important as the kind of injury he has received. But this does not mean that the physician should remain idle. After attention to the immediate surgical condition his purpose should be to establish a base line from which he can measure any changes in the patient's condition. The depth of unconsciousness and the behaviour of the patient should be accurately assessed, and abnormal signs should be observed by routine examination. A lumbar puncture should usually be performed, not just because blood may be found, or because the pressure may be raised, but because an increase in the amount of blood or of pressure may indicate the progress of a complication such as an increasing intracerebral, subdural, or extradural haemorrhage. Patterson<sup>13</sup> has recently described in some detail the kind of changes which may be expected in the cerebrospinal fluid in the acute stages of head injury. X-ray examination of the skull may indicate a depressed fracture, or one involving sinuses or the middle meningeal region which may call for surgical intervention, or the electro-encephalogram may be used to follow the progress of the general cerebral condition.<sup>14</sup> The problem is primarily one of diagnosis rather than of treatment.

The actual differential diagnosis of complications when they arise may indeed be difficult, and most surgeons will have recourse to exploratory burr holes if there is any suspicion that a deterioration in the patient's condition is due to extracerebral bleeding, proceeding to exploratory

<sup>1</sup> *Lancet*, 1943, 2, 211.<sup>2</sup> *Ibid.*, p. 689.<sup>3</sup> *Ibid.*, 1944, 1, 44.<sup>4</sup> *British Medical Journal*, 1944, 1, 33.<sup>5</sup> *Brit. J. Surg.*, 1918, 5, 555.<sup>6</sup> *Lancet*, 1941, 1, 593.<sup>7</sup> *Glasgow med. J.*, 1942, 138, 77.<sup>8</sup> *Lancet*, 1941, 1, 371.<sup>9</sup> *Brain*, 1941, 64, 93.<sup>10</sup> *Ibid.*, p. 223.<sup>11</sup> *Lancet*, 1943, 2, 438.<sup>12</sup> *Ibid.*, 1943, 1, 7.<sup>13</sup> *J. Neurol. Psychiat.*, 1943, 6, 87.<sup>14</sup> *Ibid.*, 1941, 4, 107.

needling if intracerebral blood is suspected. Once the possibility of any of these complications has been raised, the investigations may well pass into the sphere of the experienced neurosurgeon, who will prepare for ventriculography and craniotomy if necessary. If the watchful clinician finds no sign of deterioration in the patient's condition he should treat him by giving him every chance to survive the period of maximal cerebral commotion. He should be kept quiet by such drugs as chloral or intramuscular paraldehyde, should receive nourishing fluids by mouth unless coma is so deep as to cause the risk of aspiration, and should get all the nursing that will conserve his powers of recovery. There is no warrant at all for dehydration. The patient should not be restrained, and the confused, mildly resistive patient is better sitting in an armchair than being unnecessarily restrained in bed. It may not seem satisfactory merely to remain watchful in the acute stages of head injury, but the results justify the self-discipline which such an attitude requires.

### TUBERCULOSIS IN WARTIME

One of the outstanding and now well-known features of vital statistics during the past 100 years has been the rapid rate of decline in mortality from tuberculosis. In 1851-5 the standardized death rate per million was 3,638 for all forms of tuberculosis, and 2,890 for respiratory tuberculosis. The corresponding rates for 1938 were 602 and 476, about one-sixth of their former level. Mortality from tuberculosis provides a sensitive index of prevailing economic and environmental conditions, and when war broke out thirty years ago the curve of mortality ceased to go down, and instead rose continuously from 1914 to 1918. The war over, down went tuberculosis mortality once more. A disquieting feature of the wartime rise was the increase in mortality among young adults, and the death rate among them remained above the pre-war level for some years after 1918, the rate of decline being more gradual for young women than for young men. In so far as one factor in tuberculosis mortality was concerned, it was thought that increased knowledge of nutrition and the better distribution of food would place this country in a better position in 1939 to stem a possible rising tide of mortality from tuberculosis. But the death rate from all forms went up. In 1939-42 the deaths from respiratory tuberculosis numbered 21,544, 23,660, 23,633, 20,983; and from other forms, 4,080, 4,484, 5,036, 4,560. Much of the higher mortality in 1940-1 could be attributed to the increased risk of dying to which tuberculous patients were exposed in the highly abnormal circumstances of these two years, and this probably explains the fall in mortality during 1942. A distinction must be made between increased mortality and increased incidence, but as there has been a rise in the incidence of tuberculosis during the war this will sooner or later be reflected in the mortality rate. No statistical data in age groups will be available for the whole country for some time. The effect of war on tuberculosis in London has been examined by Dr. W. Allen Daley and Mr. B. Benjamin, whose interesting analysis in these columns two years ago<sup>1</sup> was recently

followed up by a further communication.<sup>2</sup> In the latter article these authors state that the number of new pulmonary cases per thousand in 1942 was half the 1941 rate for the age groups 0-4 and 5-14, but was 174% and 226% of the 1938 rate. For ages 15 and over the incidence of pulmonary tuberculosis rose in 1942, and the infection rate was 130% of the 1938 rate. In each of the above groups the death rate from pulmonary tuberculosis declined in 1942: the tuberculosis death rate among London children was only slightly higher than the peace time level, but for adults it was 136% of the 1938 rate. The trend of tuberculosis in London has probably been affected by the movement of the population, especially by the return of evacuated children during the second half of the war; this increased the numbers at risk, but did not in proportion increase the incidence of the disease.

In our opening pages this week Dr. Percy Stocks and Dr. E. Lewis-Fanning examine the increase of respiratory tuberculosis in England and Wales during the present war by relating the notifications of tuberculosis to the death among notified cases. In the past notification of tuberculosis has not always been a trustworthy guide to the actual incidence, but Stocks and Lewis-Fanning are satisfied that in the recent pre-war years the trend of notification was consistent with that of mortality among notified cases. Each year of this war there has been an increase in the notification of respiratory tuberculosis: 42,500 new cases were reported in 1943, compared with 34,930 in 1939. The deaths of notified persons rose from 19,793 in 1939 to 21,480 in 1940, and then fell during the next three years to 18,150 in 1943. The introduction of mass radiography would tend temporarily to increase the notification rate but the inclusion of persons who would normally escape notification can form only a part of the increased incidence, since there has been no corresponding decline, but rather a rise, in the deaths from tuberculosis of unnotified persons. The deterioration of the standard of notification may have been due, in part, to the widespread movement of population. Stocks and Lewis-Fanning attribute a part of the rise in the deaths during 1940-1 to the effect of the severe conditions of that period on persons already notified: they estimate that 2,900 notified patients died during 1940-1 who would have normally survived until 1942. They also reckon that during 1940-1 respiratory tuberculosis killed off 1,500 notified and 1,000 unnotified persons who in normal times would not have died of the disease. Comparing the actual deaths among notified cases between 1940-3 with the deaths that would have been expected if these had been years of peace, the authors show that in these four years 6,000 deaths from respiratory tuberculosis may be directly attributed to war conditions, distributed thus: about 1,200 in 1940-1, about 1,900 in 1942, and about 3,000 in 1943.

### RESEARCH INTO HEARING AND DEAFNESS

By arrangement with the Medical Research Council a otological research unit has been established at the National Hospital for Nervous Diseases, Queen Square, London W.C.1. It is to be jointly maintained by the council and the hospital, as in the case of the existing neurologi-

<sup>1</sup> *British Medical Journal*, 1942, 2, 417.

<sup>2</sup> *British Medical Journal*, 1943, 2, 712.

research unit. The director is Dr. C. S. Hallpike, a whole-time member of the council's scientific staff, and aural physician to the hospital. The M.R.C. have also appointed three new committees to advise and assist them in promoting a general programme of research work into problems of deafness. These will deal with the following divisions of the subject: (a) medical and surgical problems of the causation, prevention, and treatment of deafness (chairman: Prof. H. Cohen, University of Liverpool); (b) electro-acoustical problems relating to the design and application of instruments used in the investigation and alleviation of deafness (chairman: Dr. W. G. Radley, Post Office Research Station); (c) problems relating to the educational treatment of deafness in children and adults (chairman: Prof. F. C. Bartlett, University of Cambridge).

### AETIOLOGY OF NEONATAL DIARRHOEA

Outbreaks of diarrhoea among infants in maternity units have lately been causing concern both here and in America. It is probable that the disease is not a new entity but rather that it has been brought into prominence by more careful recording and investigation in recent years. Craig,<sup>1</sup> in 1936, described the clinical and pathological features of the infection as seen during the previous three and a half years in a maternity department in Edinburgh: mild dyspepsia, usually after the introduction of cow's milk into the feeds; listlessness; loss of appetite; weight progress slight or nil; frequent, watery, foul-smelling stools; some fever; then progressive loss of weight, and vomiting, sometimes of blood-streaked mucus. Ulcerative stomatitis was a common complication. Dehydration and toxæmia, with the infant drifting into a semi-comatose state, completed the downward course to death in 7 to 14 days. At necropsy hyperaemia and swelling of the intestinal mucosa with enlarged Peyer's patches and mesenteric glands was a constant finding in 11 fatal cases. Other workers have remarked on the paucity of pathological changes post mortem.

The aetiology of the condition is obscure. In connexion with the outbreaks described by Ormiston,<sup>2</sup> bacteriologists<sup>3</sup> in the E.P.H.L. Service made an exhaustive examination of the intestinal flora of affected cases and, for comparison, of normal infants. No intestinal pathogens, bacterial or protozoal, were isolated, and no evidence was found of any bacterial toxin—e.g., of staphylococcus or the Welch bacillus—likely to cause the diarrhoea. A preformed toxin in the breast-milk of feeding mothers due to enterotoxigenic staphylococci was also considered, but the infection is comparatively rare and usually mild in breast-fed babies, and *Staph. aureus* is present in the breast-milk of more than half the healthy mothers with healthy babies. It was concluded that the two likeliest causes were either (1) a systemic infection or a general metabolic disturbance leading secondarily to diarrhoea and vomiting, or (2) a primary virus infection of the alimentary tract. Virus infections of the gut are rare, but support for a virus aetiology in neonatal diarrhoea comes from Baltimore in a report from Light and Hodes,<sup>4</sup> who were able to reproduce a clinically similar condition in young calves by the nasal instillation of Seitz-filtered stools from affected babies in four different outbreaks. At least 8 c.cm. of the filtrate was required to produce a dysenteric type of diarrhoea after an incubation period of 2 to 5 days, and, as some of the material was almost certainly swallowed, the infection may have been primarily intestinal. In one series of tests the causative agent was passed

through twenty-nine calves, ten times with filtered material; in others two, four, and eight passages were successfully effected. The diarrhoea in the calf tended to persist, with an average duration of three weeks and a case mortality of 13%. Post-mortem examination showed hyperaemia of the intestinal mucosa with enlargement of the lymphoid tissue and of mesenteric glands, a picture remarkably similar to that described in infants by Craig. Cross-infection by contact occurred, giving rise to a mild form of the disease. Stools from four healthy calves and eight healthy infants failed to evoke any diarrhoea in inoculated calves, while other tests suggested that the condition was not calf scours or the virus infection pneumo-enteritis. Infected calves were resistant to subsequent inoculation, and a few experiments indicated that a specific antibody had developed in the sera of some of the affected infants. One curious finding was that the active principle of this calf diarrhoea was not destroyed by five minutes' boiling, though inactivated after ten minutes' boiling; similarly, it resisted heating at 70° C. for 1 hour, but not at 80° C. for 1 hour. These experiments will evoke much interest, and if corroborated they may give a clue to the analogous gastro-enteritis of older infants. Meanwhile, it must not be forgotten that severe diarrhoea and vomiting is a rarity in breast-fed babies, and every encouragement must be given to the establishment of breast-feeding in the maternity department and afterwards during the first six months of life.

### POISONING THE ENDOCRINE GLANDS

Research in endocrinology has usually followed three lines: the observation of disordered states, the effects of extracts, and the effects of extirpation. Fruitful though these methods have been, they have brought us but a little way towards an understanding of this most complex branch of medicine, and any new approach is of great interest. In the last few months we have seen the first-fruits of a pharmacological attack. The fascinating history of the discovery of thiouracil, beginning with observations of the poisonous effects of cabbage on the thyroid glands of rabbits, was told recently in this *Journal*.<sup>1</sup> Another example of the new approach is given by recent reports on the action of alloxan on the islets of Langerhans. Jacobs<sup>2</sup> in 1937 reported hypoglycaemia after the injection of alloxan into rabbits, but the observation seems to have remained unexplained and forgotten until its accidental rediscovery by Shaw Dunn<sup>3</sup> and his colleagues in 1943. The injection of this derivative of uric acid into rats and rabbits produces a transient rise in blood sugar, then a phase of hypoglycaemia which is sometimes fatal, and finally, in those animals which survive, necrosis of the islets of Langerhans and a condition resembling diabetes in man not only in its clinical signs but in its susceptibility to treatment with insulin. Shaw Dunn suggested that the hypoglycaemic phase was due to overstimulation of the islets and the ultimate diabetes to their death through exhaustion, but this hypothesis did not explain the first hyperglycaemic phase. The work, which has been amply confirmed by many workers, has been continued by Hughes, Ware, and Young,<sup>4</sup> who have found that islet changes were present within five minutes of the injection of alloxan. They failed to discover any histological evidence of a phase of over-activity, and found, moreover, that in well-fed animals the hypoglycaemia was comparatively mild. They succeeded in reproducing

<sup>4</sup> *J. Path. Bact.*, 1943, 55, 245.

<sup>5</sup> *Lancet*, 1944, 1, 148.

tactly the blood sugar changes of their alloxan-poisoned rabbits by giving a dose of protamine-zinc-insulin equal to the insulin content of the rabbit's pancreas (10 units), and two doses of adrenalin, one with the insulin and one an hour later. This suggested a simpler explanation than Dunn's: that the first hyperglycaemia is due to the release of adrenaline, and the hypoglycaemia to the liberation from dying islets of their store of preformed insulin, in some such manner as the delay in the action of thiouracil may be due to the body's store of preformed thyroxine.

The importance of this work is threefold. In the first place we now have a simple method of inducing diabetes mellitus in experimental animals without recourse to surgery. In the second place the possibility has arisen that the cause of natural diabetes may be an error in metabolism resulting in the excessive production of alloxan. In the third place, once again within a few months, attention has been drawn to a substance which has a selectively poisonous action on an endocrine gland. A search for further endocrine poisons is due.

### LEPROSY IN CHILDREN

During the last quarter of a century of renewed interest in leprosy it has been recognized more and more that the key to the problem of lowering the incidence of the disease lies in the prevention of the frequent infections in childhood. During the last seven years this aspect of the question has been closely studied at the Silver Jubilee Clinic, Madras, by Dr. R. G. Cochrane, who has summarized his investigations in three Madras University lectures (published by the Government Press, Madras). The lecturer quotes with approval the evidence given in the work on leprosy of Rogers and Muir to show that a large proportion of leprosy infections take place before the age of 15 years among children living in the same house as in open case of leprosy—that is, one discharging lepra bacilli from lesions of the skin and nose. The Madras study of 551 children showed that over 70% of the serious epromatous cases, and of the incipient lesions of childhood of which Dr. Cochrane has called attention, were traced to contact with open cases of leprosy. In the mild resistant, and little-infective, neural type, including tuberculoid cases, such contact was traced in only 47%. Moreover, twice as many cases with multiple lesions were traced to house contact as those of milder infection with only one or two lesions. On classifying the cases of intrafamilial or house contacts, and extrafamilial or chance contacts, it was found that 90.4% of the incipient and 68% of the lepromatous cases were family house infections, against 55% of the mild neural cases. Dr. Cochrane therefore agrees with earlier writers in holding that the prevention of house contacts of healthy children with open infective types of leprosy will do more than any other single measure towards the control of leprosy. Family susceptibility is also discussed, and data are given to show that child infections were nearly as frequent (51.2%) among children living as co-tenants with non-relations as among those residing with blood relations (56%). Family susceptibility is thus regarded as of minor importance. In spite of recent improvements in the treatment of leprosy, prevention remains easier, as well as better, than cure. It is therefore of interest to recall that as early as 1897, on the advice of Ehlers of Copenhagen, Iceland prohibited children under 15 from living in any house containing an infective leper, with good results. The Madras work should hasten the time when this all-important preventive measure is far more generally adopted in leprosy-infected countries.

### DISINFECTANTS

An aspect of hygiene which does not always get the attention it deserves is the choice of a disinfectant and its correct use. When the purpose concerned is really deodorant effect, as in urinals and water-closets, or fly-repellant action, as in refuse heaps, other considerations apply, and a bad choice need bring no disaster; but where it is really necessary to disinfect with certainty an efficient agent must be used, and used rightly. Excreta, linen, and various utensils, baths, and sometimes beds and floors, may require chemical disinfection for definite reasons. This sort of task is made easier by freedom from one limiting consideration which enters into the application of disinfectants to the skin, since it does not matter much if the substance used is toxic or irritant. The main requirement is germicidal efficiency, and secondary though important ones are availability and cheapness. Efficiency for some of these purposes means capacity to disinfect despite the presence of organic matter, in the form of faeces, mucoid secretions or pus. Whole classes of disinfectant are excluded by their incapacity to act in such an environment, excellent as they may be under more favourable conditions: these include oxidizing agents such as potassium permanganate and anything acting by the liberation of chlorine, though calcium hypochlorite if used very liberally may serve for some purposes. The class of disinfectant best adapted to this type of use is that obtained from coal-tar distillates, and includes phenol, cresols, and the tar acids of higher boiling-point and lower solubility in water which are the active constituents of many white and black fluids forming emulsions on dilution. Phenol is thoroughly reliable if used in adequate strength—usually 5%—even in the presence of plentiful organic matter. Lysol, which is a soapy solution of cresols, acts similarly in 2% solution—that is, its germicidal activity is greater than that of phenol and not greatly impaired by organic matter. The choice between these two, unless the solvent and cleansing action exerted by the soap in lysol is required, as in the disinfection of baths, is largely a question of price. During the war another consideration has arisen: phenol and certain cresols are the raw material of important plastics, and economy in their medical use was called for in consequence. It is reassuring to hear, as announced in this *Journal* recently, that the phenol supply position has now improved. White and black fluids have some advantages over phenol and cresol, and some drawbacks. They are less poisonous but more messy, more efficient in favourable conditions but much more susceptible to the quenching effect of organic matter: a fluid having a Rideal-Walker coefficient of 20 may have a Chick-Martin coefficient of only 4, which fairly reflects the difference between action in pure water and action under moderately unfavourable natural conditions. A good fluid of this type, used according to the directions of a responsible manufacturer, is nevertheless a valuable and reliable agent for many purposes, and certainly the best choice if lysol or phenol are unobtainable. Some of these fluids, owing to their freedom from caustic effect, may also be used if necessary on the skin or even, as has recently been pointed out in our correspondence columns, for the first-aid treatment of wounds.

The London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street, W.C.) announces an address "Teaching and Practice in Preventive Medicine" to be given on Friday, June 2, at 3.30 p.m., by Dr. J. M. Mackin, recently appointed Professor of Public Health in the University of London. Lord Woolton will take the chair.

## A NOTE ON THE VITAL STATISTICS OF ICELAND

BY

AGNES TELEKY, Dr. Rer. Pol.

For obvious reasons the vital statistics of Iceland have a more direct interest for English and American readers now than they would have had five years ago, and, on the suggestion of Prof. Greenwood, I have brought together some facts which are worthy of consideration.

Nearly 20 years ago Greenwood (*J. roy. stat. Soc.*, 1924, 87, 493) made a detailed comparison of the rates of mortality in England and Wales and Sweden for ages from 15 years upwards, supplementing this by a reference to earlier years of life. This is the story. A century ago males in Sweden died at lower rates than males in England at all ages under 35 and at higher rates at older ages. Females at all ages died at higher rates in England and Wales. This state of affairs gradually changed,

which 1911 and 1933 are the central years. The results are shown in Table I and, as percentages of the corresponding English rates, in Table II. In the last generation Iceland and Sweden had a similar relation to England and Wales: the unfavourable mortality in adolescence and young manhood is somewhat accentuated in Iceland, partly because of the greater chance of death from sea risks in a population so largely dependent on the sea for a livelihood, partly perhaps a mere chance fluctuation.

In 1933 Iceland had lost something of her advantage in early childhood, but in later ages was in much the same relative position as a generation earlier. Except in the first five years of life and at those later ages in which Sweden had, and retains, a considerable advantage over England and Wales, the change between 1911 and 1933 has been much in favour of Sweden. Only in the age group 20-25 is the mortality rate in Sweden appreciably higher than in England and Wales; in the age group 5-10 the Swedish rates are more than 30% better than those of England and Wales. As the industrialization of Sweden has presumably continued, the comparison is not

By the beginning of the twentieth century the inhabitants of England and Wales had, after infancy and down to early adult life (about age 30 in males and 35 in females), much lower rates of mortality than Sweden, and at later adult ages much higher rates of mortality. This contrast of advantage in later childhood and earlier adult life with disadvantage in later adult life has been thought to characterize industrialized States as compared with agricultural States at the same level of civilization, because a roughly similar contrast emerges as between urban and rural districts of England and Wales.

Greenwood's paper brought the story down to the last generation. The other Scandinavian countries showed a roughly similar state of affairs. Although, of course, these countries have developed some industries, they may still be considered "agricultural"—if we extend the term agricultural to cover sea-faring occupations—and Iceland belongs to the same group both racially and industrially. In the last generation there has been a change. To bring this out I have compared the rates of mortality of England and Wales, Sweden, and Iceland for the years 1911 and 1933. As the population of Iceland is very small the rates here are based upon the quinquennia of

flattering to English rates, and may suggest subjects for inquiry. Iceland, we have seen, can be regarded as bearing the same relation to England and Wales now as Sweden had a generation ago.

The effect of the war on the distribution of doctors in the United States has been the subject of a report by Drs. Perrott and Davis, and this was discussed in the *Journal of the American Medical Association* of Jan. 15. The survey reveals that the war has already withdrawn something like one-third of the active practitioners, the number of civilian doctors having fallen precipitously—from more than 120,000 on Jan. 1, 1942, to about 85,000 at the end of 1943. Concurrently the recruitment of civilian doctors has diminished greatly and the armed Services expect to take 80% of all new medical graduates. During the past twenty years there has been a trend for the States rich in medical man-power to become richer and for the States poor in medical man-power to become poorer. The analysis made by these officers of the U.S. Public Health Service, says the *J.A.M.A.*, serves to indicate certain aspects of the distribution of physicians to which attention may well be directed in post-war planning for medical services.

## A NATIONAL WATER POLICY

Proposals for ensuring that all reasonable needs for water by householders, industry, and agriculture can in future be met, and met speedily and without avoidable waste, are made in a White Paper\* presented to Parliament on April 18 by the Minister of Health, the Minister of Agriculture and Fisheries, and the Secretary of State for Scotland. "There is in this country ample water for all needs. The problem is not one of total resources but of organization and distribution." The object of the Government's proposals is therefore the shaping of a national water policy which will ensure a planned and economical use of the resources of the country and efficient administration of supply services. Some of the main proposals are outlined below:

The Health Ministers, whose powers are at present vague and ill defined, to be given the express statutory duty of promoting the provision of adequate water supplies and the conservation of water resources.

Central planning of water policy to be the function of the Health Ministers; to be based on comprehensive information, systematically collected and assessed, regarding water resources and needs; and to be applied by a simplified system of Ministerial orders. Interested parties to have full opportunity to put their views before the Minister; Orders on certain matters to be subject to review by Parliament by reason of their intrinsic importance or because of their effect on the interests of the general public or of individuals.

The Government's Central Advisory Water Committee to be reconstituted as a statutory body. It will advise not only on matters referred to it by any Government Department but also on its own initiative on any question within its ambit. A somewhat similar body to be set up for Scotland.

Surveys of the efficiency of water supply services to be carried out regularly by expert central staffs. The general framework of existing local organization to be retained, but powers of the Minister of Health to be strengthened, and amalgamation of undertakings to be encouraged and, if necessary, enforced to secure efficiency and economy. Special steps to be taken to protect water resources, especially underground water, against misuse, waste, and pollution.

Provision of Exchequer grants totalling £15,000,000 for England and Wales, and £6,375,000 for Scotland, for extension of piped water supplies and sewerage in rural areas.

This programme means new legislation. In advance of general legislation, a Bill is to be presented to Parliament this session authorizing the grants for water supply and sewerage in rural areas as part of the general reconstruction programme. While the problem in Scotland is broadly similar to that in England and Wales, account must be taken of differences in geography, local government structure, law, and water supply organization in the two countries. The Government's proposals, as affecting the Scottish service, are described in a separate section of the White Paper.

## SPECIAL RATIONS FOR INVALIDS

The Ministry of Food announces that, in accordance with the recommendations of the Food Rationing (Special Diets) Advisory Committee, the following special food allowances have been made for invalids and sick persons.

**Priority Liquid Milk in Actinomycosis.**—Patients suffering from actinomycosis may have two pints of priority liquid milk a day. This condition will fall in Class 1 (a) of the schedule of diseases. Medical certificates will be valid for a period of three months, and renewable for further three-monthly periods as in cases of tuberculosis.

**Extra Meat in Hypoproteinaemia.**—Three extra meat rations a week are now available in proven cases of hypoproteinaemia from any cause. Applications, supported by a detailed medical certificate, must be made to the local food office. The extra rations will be for an initial period of six months, renewable on production of a fresh medical certificate stating that the patient is still suffering from this condition.

**Dried Bananas in Coeliac Disease.**—The Red Cross and St. John War Organization is providing dried bananas, at the rate of three and a half pounds a week, free to patients suffering from coeliac disease. This is in addition to the extra meat already provided by the Ministry. Applications must be made to the local Food Office supported by detailed medical evidence, including the clinical data on which the

diagnosis is based, unless such evidence has already been given with an application for extra meat. Supplies will be provided for three months, at the end of which time a fresh medical certificate will be required.

**Household Milk Powder.**—Two tins a week of household milk powder (dried skimmed milk powder) are now available against a medical certificate for persons suffering from steatorrhoea, gout, or infective hepatitis (catarrhal jaundice), toxic jaundice, and cirrhosis of the liver (but not obstructive jaundice). The certificate must give the clinical and biochemical data on which the diagnosis of steatorrhoea or gout is based. Applications should be made to the local Food Office. Supplies will be arranged for an initial period of three months, when a fresh certificate will be required.

## APPROVED NAMES OF DRUGS

The General Medical Council has approved the following names for substances produced by British manufacturers, in some instances under licence granted by the Comptroller-General of Patents, Designs and Trade Marks. The question of including these in the *British Pharmacopoeia* is under consideration, and if that is done the intention is that the approved name shall become the official title. Recognition of an approved name does not imply that the name will necessarily be admitted to the *Pharmacopoeia*.

Approved Names	Other Names
Desoxycortone acetate .. ..	Δ-4-pregnen-21-ol-3 : 20-dione acetate
	Desoxycorticosterone acetate.
Dicoumarol .. ..	3 : 3'-methylene-bis-(4-hydroxycoumarin).
Dimethylstilbamidine .. ..	4 : 4'-diamidino-α : β-dimethylstilbene.
Pentamidine .. ..	Diamidino-diphenoxypentane.
Propamidine .. ..	Diamidino-phenoxypropant.
Stilbamidine .. ..	Diaminosilbene.
Sulphadimethylpyrimidine .. ..	2-(4-aminobenzene)sulphonylamino-4 : 6-dimethylpyrimidine.
	Sulphamezathine.
Thiomersalate .. ..	Sodium ethylmercurithiosalicylate.
	Merthiolate.

## Medico-Legal

### A "CURE" FOR THE DRINK HABIT

On March 2 at Bow Street Police Court, before Mr. McKenna, the Pharmaceutical Society of Great Britain prosecuted F. Cavendish-Longman, Ltd., publishers, trading as L. E. Venn, under the Pharmacy and Medicines Act, 1941, for selling an article recommended as a medicine without disclosing on the label the composition of the substance. Mr. R. A. Robinson was counsel for the prosecution and Mr. Du Cann was counsel for the defence. The plea was not guilty.

Mr. Robinson stated that the defendants advertised and sold a substance in powder form recommended as a cure for the drink habit. The public were invited by advertisement to apply for particulars and a free sample. An inspector employed by the Pharmaceutical Society replied to the advertisement and received a circular letter, booklet, and other advertising matter. In the booklet and other publications the dangers of alcoholism were stressed, and medical authorities were quoted for the statement that the drink habit led to serious diseases of the liver, kidneys, heart, and other organs. Later, further circulars were received by the inspector, who then sent 30s. to the defendants, from whom he received fifty powders, unlabelled. The directions were to take a powder with meals three times daily. The powders had been analysed and found to contain in each powder about 2 gr. of potassium bromid and about 5 gr. of lactose. Counsel contended that alcoholism was an infirmity within the meaning of the Act and that the drink cure was also recommended as a preventive of the various diseases to which excessive drinking was said to lead. The advertising matter included statements that the powders could be administered to the drink addict, without his knowledge, in beer, spirits, or tea, and that a distaste for alcoholic drinks would result. The inspector has not given defendants any particulars beyond his name and address so it could not be argued that the case came within the exemption allowed by the Act in favour of treatments prescribed by reference to the needs of a particular person.

Mr. Du Cann claimed that the advertisements did not recommend the substance as a medicine within the meaning of the Act, and that alcoholism was not an infirmity or ailment. Further, that the treatment was designed to meet the needs of particular persons. The company had now altered the labels and was now declaring the composition of the powders on the label.

The magistrate ruled against Mr. Du Cann, and found as a fact that alcoholism was an infirmity for the treatment of which the cure was recommended. He imposed a fine of £2 with £5 costs for the prosecution.

# An EXPLANATION

on

The present delays in the deliveries to patients  
of Anatomical, Surgical and Orthopaedic Belts,  
Spinal Supports, Braces and similar Appliances.

The undermentioned makers respectfully desire to make the following observations on the causes which affect deliveries of prescription orders to patients.

- (1) The present limitation of labour and in particular of trained labour engaged upon the making of these appliances.
- (2) An increase in the number of prescription orders now being received primarily to meet the needs of persons—particularly of women—engaged in the Services or on work of National importance.

Our labour problem is receiving the consideration of the appropriate Government Departments, and every effort is being made to restore, as far as possible, the prompt deliveries which have characterised our pre-war services to the medical profession and to their patients.

We trust the foregoing explanation will be received at a bona fide of our efforts to render the best possible service under difficult conditions.

## ASCABIOL<sup>9</sup>

TRADE MARK

*brand of benzyl benzoate emulsion*

*for the treatment of*  
**scabies**

A single application of benzyl benzoate emulsion, provided it is thorough, will usually cure a case of scabies. The chief advantage of benzyl benzoate over some other sarcopticidal agents is the rarity of dermatitis following its use, and recently the formula of 'Ascabiol' has been modified so that skin irritation following its use is minimal.

Pads of instruction cards for patients and a pamphlet are available. Pediculosis Capitis—

Benzyl benzoate destroys lice and, as prescribed in 'Ascabiol' emulsion, also dissolves the cement by which the nits adhere to the hairs. Instead of by the painstaking use of the small-tooth-comb, the nits are removed simply by washing the hair.

'Ascabiol' brand of emulsion contains 25 per cent. benzyl benzoate, and is supplied as follows:—

Bottles of 4 ozs.

Bottles of 80 ozs.

# 'Stypven' RUSSELL VIPER VENOM

the most effective local hæmostatic yet discovered

A dilute solution of Russell Viper Venom is the most effective local hæmostatic which has so far been discovered. It may be used in all types of hæmorrhage where the solution can be applied directly to the bleeding

point. 'Stypven' is invaluable in emergency when hæmorrhage cannot be controlled by every-day methods. It is also being increasingly used in place of brain extract for the measurement of prothrombin time.

*Dried venom and solvent to make 1 c.c., 1:10,000 solution, 1/6 (Purchase Tax 2½d.)*

*Dried venom and solvent to make 5 c.c., 1:10,000 solution, 3/0 (Purchase Tax 4½d.)*

**PHILIPS  
MOBILE  
DIAGNOSTIC  
X-RAY UNITS**

This fine '90/30 Mobile X-Ray Unit, ideal for ward use and for emergency purposes, is widely recognised as the foremost equipment of its class. Modern in design and conception and manufactured in large series, it incorporates numerous outstanding technical advantages which are described in full in publication XMI, available on request. In radiographic performance the MOBILE 'D' is superb and, above all, it is thoroughly reliable. Authorised purchasers will find this equipment a highly satisfactory investment. Enquiries are invited.

QUICK DELIVERY • BRITISH MADE THROUGHOUT  
(INCLUDING TUBE)

## FOREIGN BROTHERS OF THE BARBER-SURGEONS

Sydney Young, in the *Annals of the Barber-Surgeons' Company*, says of the foreign brothers that, with very few exceptions, they were all of them practising surgeons who had not been apprenticed to freemen of the Company. He also states that a very small number of pure barbers are entered on the records as foreign brothers, and hints that this may be due to errors of description on the part of the clerk who kept the books. Perhaps this is not true of every case, for on "April 17, 1599, Michael Bullocke complaineth of William Webbe forren brother for working with Henry Needham being not ceased with him and for grindeinge of rasres." A surgical foreign brother would hardly have submitted to grinding razors even at so early a date as this. And in the articles of 1555 it is ordained that "no floryner being no freeman shall . . . to make cleane teethe, to shave poll or washe a bearde or to tryme any man but within the Liberty where he dwelleth." This last note confirms Young's conclusions that nearly all foreign brothers had not been apprenticed to freemen of the Company. Two other references to foreign barbers occur in 1606 and 1635. In the early years of the Company's history the numbers of foreign brothers seem to have been small. Thus, in 1578 a levy, in answer to a precept by the Lord Mayor, was made by the Company on 90 freemen and upon 10 "foreins." But by the opening years of the eighteenth century there was a large increase in the numbers. This was probably due in part to the influx of foreign surgeons which occurred with the revocation of the Edict of Nantes in 1685 and with the Declaration of Indulgence in 1687.

The By-laws of 1606 contain among other details the oath of a foreign surgeon. In 1610 James Blackburne was examined and found "fit and allowed to practize (in that chirurgicall parte of surgerye touching the generative partes of women and bringing them to bedd in their dangerous and difficult labours)." He was therefore "sworne and admitted a floryner brother." The apprentice books of the Company at Barbers' Hall date from 1658. The earlier volumes contain practically no reference to foreign brothers; but as said earlier there are numerous mentions of this class of practitioner from 1700 to 1745. If a surgeon who had not served his apprenticeship to a freeman of the Company wished to practise within the Company's jurisdiction (City of London and circuit of seven miles round) he had either to join the Company as a foreign brother or, in theory at least, start again from the beginning by being bound apprentice to a freeman. This would have involved a delay of at least seven years. On admission as foreign brothers these men paid a fine, seven guineas was the usual amount, and had to satisfy the court, by the production of their indentures to country surgeons, that they had duly served an apprenticeship of seven years; they had also to undergo an examination by the Company's examiners.

Very occasionally a man was recommended by some person of quality and then the court dispensed with the production of indentures. All sea surgeons were foreign brothers; and Young says that some country surgeons became foreign brothers for the sake of the extra status conferred by possession of a diploma from Barber-Surgeons' Hall. The first really well known surgeon to become a foreign brother of whom I have knowledge is Paul Buissière, elected Aug. 20, 1691. All that is known of him is recorded by the late George Peachey in his excellent *Memoir of William and John Hunter*. From now on we find that some of these foreign brothers purchased their freedom, and so we often meet with cases on the books where an apprentice was bound to So-and-so, surgeon and foreign brother. (But in this connexion it is to be noted that Young states that in 1614, when a "foreigner" was admitted to the livery he paid £5 for yeomanry and £5 for livery fines in one payment. Young had found it difficult to determine what the exact status of the foreign brother really was. I am inclined to believe that it varied with the times.)

I suppose that the best-known foreign brother is John Ranby, surgeon to St. Thomas's Hospital and surgeon-general to George II. He was present at Dettingen and is generally supposed to be the surgeon mentioned by Fielding in *Tom Jones*. Ranby was the first master of the Company of Surgeons after the dissolution in 1745. Among his pupils was Sir Caesar Hawkins, but Hawkins was not bound apprentice at the Hall as he had already served his time with his father, Mr. Caesar Hawkins, of Ludlow, Salop. He obtained the freedom by purchase and was not a foreign brother. Another well-known foreign brother was David Middleton of St. George's and Surgeon-General to the Army. Of foreigners I may record the names of Figeul, Chovel, and Lamarque, all of whom were engaged in the teaching of anatomy in London in the early years of the eighteenth century.

R. R. J.

## Blood Cultures in Staphylococcal Septicaemia

SIR.—With the advent of penicillin there has come an increased interest in the treatment of staphylococcal septicaemia. In the *Journal* of April 15 four cases were reported with two deaths; in the same symposium were three cases of acute osteomyelitis with positive blood cultures—all recovered. In none of these cases, apparently, had repeated quantitative blood cultures been done, so that there is no record available of the severity of the blood-stream infection.

At a recent meeting of the Clinical Section of the R.S.M. similar cases were reported from St. Mary's Hospital without any quantitative blood-culture estimations. All these cases had been treated with penicillin. Valentine and Butler (*Lancet*, 1943, I, 194), in reporting 29 consecutive cases of staphylococcal septicaemia, showed that in 9 fulminating cases the colony counts rose to 500-1,000 per c.c.m. of blood. All died. In the next less severe group the counts were above 30 and rose to over 100 in the fatal cases; 3 patients survived out of 8. In the last group (12 cases) the colony counts never rose above 20; all lived except one patient. Similar figures have been reported by McClellan and Goldbloom from Canada (*Canad. med. Ass. J.*, 1942, 146, 136). A good many of the cases in the former paper were treated before the introduction of sulphathiazole. Since that paper was written I have had three patients who recovered whose colony counts rose to 95, 45, and 37 per c.c.m. respectively; they all had intensive treatment with sulphathiazole.

It is apparent from these figures that staphylococcal blood-stream infection is not always a fatal condition, but that it rapidly becomes so if the blood culture rises to 100 or more colonies per c.c.m. of blood. In order to show that penicillin cures cases of staphylococcal septicaemia it is not enough to state that the blood culture was positive and then became negative. It must be shown that patients recover whose blood cultures have reached the high figures already quoted above. This has been done in a few cases, but I should urge those who now have the opportunity to use penicillin for staphylococcal septicaemia to prove or disprove this important fact. In my opinion no case of staphylococcal septicaemia is accurately recorded unless the results of repeated quantitative blood cultures are also given.—I am, etc.,

The London Hospital, E

E. C. B. BUTLER.

## Tuberculin Jelly in Patch Testing

SIR.—Referring to the memorandum by Dr. Donald Paterson in your issue of April 15 on the use of tuberculin jelly in patch testing, this method as introduced and applied extensively by Prof. S. Monrad of Copenhagen (1936), and his jelly and its use were described by K. A. Jensen in *Tubercle* (1937).

As a direct result of Monrad's work, I have during the past two years been preparing a similar jelly for use in the Welsh National Memorial Association, and have also supplied it for tests in the military Forces and for a complete survey of the school-children of Radnorshire by Dr. T. E. Jones Davies, M.O.H. At present it is being used in still more extensive school surveys in Wales.

My original formula followed that of Monrad, but has since been substantially altered, and is still under minor alteration. It is prepared from purified tuberculin, at a final strength from two or three times that of standard old tuberculin, and has given results slightly higher than those of Mantoux tests, 1:1,000, in the same subjects. Our medical officers report the positive reactions as being stronger and more easily read than those produced by any of the commercial patch-test materials.—I am, etc.,

Department of Tuberculosis,  
Welsh National School of Medicine, Cardiff.

W. H. TYTLER.

### Status Lymphaticus

SIR,—I write in hope of enlightenment from pathologists. Is not Dr. R. G. Cooke perpetuating a medical myth when he ascribes sudden death to status lymphaticus? (April 1, p. 457). Even if the condition does in fact exist and could be recognized by the criteria he mentions, are these criteria satisfied by the post-mortem results given? It seems that in the case he describes there were abnormalities which might provide bases for more probable explanations of the fatality.

The highly accurate work of Hammar and Boyd (confirmed by others) appears to dispose of the belief that the "persistent thymus" is an abnormality. These investigators have stated that there are no significant gross anatomical differences between the thymic and lymphatic tissues of persons who died suddenly from unknown causes and those of people said to have status lymphaticus.

My special interest lies in the fact that the lymphatic state has been held to be associated with emotional instability. In the past assertions little short of ridiculous have been made in this connexion because the studies have neglected the precaution of investigation of control material.—I am, etc.,

G. R. PEBERDY.

Major, R.A.M.C.

### Tonsillectomy in Children

SIR,—I feel that I must contradict a remark at the end of Mr. T. B. Layton's letter (March 11, p. 372). He says: "... no such administration has as yet been set up which will give that minimum of a quarter of an hour between the parent upon whom the responsibility for decision rests and the surgeon in whose hands the responsibility for advising the operation is finally put." He is writing about tonsillectomy in children. I should like to describe a system at present working, and which, I may add, appears to provide more than "that minimum" required by Mr. Layton.

All cases reported to the school medical department, whether by school medical officers, private doctors, or parents, as possibly requiring an operation have their names and addresses, together with the doctor's letter, forwarded to the hospital where the ear, nose, and throat work is carried out. These names are forwarded to the department concerned and the surgeon sends for a group of such a size that he can give personal attention to each one. The children are sent for, it being a rule that they bring parent or guardian with them. Sessions last from 2 to 2½ hours, and the number of new cases sent for is usually eight or ten. What the mother complains of, the child's history, and results of examination are noted, and it is decided whether tonsils and adenoids should be removed, or adenoids only, or whether the case should be kept under observation, or requires other treatment. In a large number of catarrhal children advice is given on general health, diet, and hygiene. If the surgeon wishes to see the children again before or after operation, as is often the case, their names are put down for a definite date any time within six months ahead, and when the time comes they are sent for, as before, with parent. In a small percentage of cases the surgeon has before him the notes of children whom he has already been treating from infancy at a welfare centre, whence these notes follow them to the school clinic at the age of 5. I cannot describe the actual work better than by quoting from the annual report I had from the surgeon for 1943:

"Of 188 cases sent up as new cases, 113 have had operations for tonsils and/or adenoids, in a good many cases only for the latter. This means that in 75 cases operation has been avoided or, for good reason, postponed. The object has been to keep in touch with the patients by consultations with their parents and doctors. The number of visits has been 231 for the 188 patients; the difference is accounted for by keeping in touch with those in whom advice has been really needed rather than active treatment, and the number is considerable.

"... At the voluntary welfare clinic is held an ear, nose, and throat session, at which children from birth to school age are seen. Notes on health, diet, and treatment are kept, and, most important

of all, on advice given. These notes follow these particular children to the school clinic; the personal element is increased by the parent knowing the doctor and what he is aiming at. In the case of these slightly subnormal children the personal effort made over long period by parent and doctor, helped by a child who likes the doctor and likes the clinic, is of far more importance than isolated visits and operations."

The actual working of the system has been by weekly sessions, and it has been found in practice that approximately three clinical sessions to one operative session is satisfactory. I feel that this compares very favourably with the consideration that these children would have had in private practice.—I am, etc.,

IAN MACKAY,  
County Medical Officer of Health, Cheshire.

### Chewing-gum or Polypus?

SIR,—About a year ago a male patient, just before reporting to a medical board for National Service, was referred to me as a probable gastric ulcer. His symptoms were vague and physical examination revealed nothing abnormal. The x-ray report stated that there was a persistent filling defect in the pre-pyloric region, the diagnosis being a pre-pyloric polypus. I was about to write a medical report to the board to this effect when a "friend" of the patient, by an indirect route, gave me the "low-down" on the case. I received information that the patient had secreted chewing gum in his teeth, which was dislodged by the tongue as he swallowed the bismuth meal. This seemed to be a possible explanation of the filling defect, and a control x-ray a few days later was quite normal. Either the patient had failed to replenish his supply of gum or, if a pledget had been swallowed, it had successfully negotiated the pylorus. Anyway, I was then able to give a report—to the disappointment of the patient—that no gastric abnormality was evident.

Having recently encountered a similar case, it seems that this method of confusing the radiologist, and thereby the surgeon, may be more familiar to certain sections of the public than to the medical profession.—I am, etc.

London, W.1.

MCNEILL LOVE.

### Teaching of Anaesthetics

SIR,—I venture to suggest that much of the difficulty of teaching anaesthetics to-day would be largely eliminated if only more consideration could be given to the following:

Modern methods, rightly demanded by patient and surgeon, do tend to give undue prominence to the employment of elaborate apparatus. We all know the advantages and disadvantages of the gases and methods that require apparatus. The fact remains, however, that a large number of anaesthetics are, and probably always will be, given by medical men who, administering only occasionally, do not wish to buy expensive machines. Again, under war conditions, machines may be unobtainable or out of repair or, again, may be of a type with which they are unfamiliar. What does so often appear to be relegated to the background is the equally, and in many cases more, important aspect of modern anaesthesia—i.e., the psychological approach of the anaesthetist to his patient—in other words, the art and practice of suitable premedication. How to employ this in its widest aspect should surely be instilled into every student, undergraduate, or postgraduate before any type of anaesthetic mask is ever placed in his hands. The drugs, syringes, etc., necessary for premedication can be easily obtained and kept in the house of every medical man without the worry entailed over maintenance and condition of only occasionally used apparatus.

It is generally agreed that a smooth induction of anaesthesia in a patient from whom all apprehension has been removed makes for smooth maintenance and smooth recovery, and if we could secure this one feature of modern anaesthesia for every patient who has to submit to an operation we should have achieved something more than worth while. These benefits can be obtained, at least to a great extent, irrespective of what type of anaesthesia is going to be employed. Even if intravenous technique be ruled out, a well-medicated patient need not, and should not, suffer any greater discomfort during a correct induction of ethyl-chloride-ether sequence, etc.

CE-ether sequence, than he would if induced, for example, by  $N_2O$ -oxygen or cyclopropane.

It has been suggested that the surgeon might object to the employment of such "antiquated" methods; the patient's recovery might be delayed, and all the other usual condemnations. Now, Sir, on any large hospital operating list there are almost always some patients who could not honestly be said to be harmed by the correct administration of ether or CE mixture for 5 to 10 minutes. It is the induction period which gives the greatest difficulty to students. Once they have mastered the art of induction the principles of maintenance by the use of ether or CE mixture can be rapidly explained, and then, if the welfare of the patient demands it, a change-over to other methods of maintenance can be effected without difficulty by the instructing anaesthetist. For the pupil: "first things first."

I suggest that until, if ever, all anaesthetics are administered by the whole-time specialist action on these lines would grant the benefits of modern methods to every patient, and would enable every medical man to give an anaesthetic when suddenly called upon to do so under conditions where the employment of mechanical methods is impossible.

With regard to the attendance of students of anaesthetics at so-called minor operations in dental and out-patient departments, I think the importance of their so doing cannot be too greatly stressed, provided there is an experienced anaesthetist in attendance who is genuinely interested in securing their proficiency. It has been said that once proficiency in anaesthetizing at so-called minor operations has been achieved, the "majors" will look after themselves. It is the so-called minor cases that so often give difficulties. True judgment, that can only come from experience, is undoubtedly essential; for example, when the surgeon, during a big abdominal case, turns to his anaesthetist and says: "I have done the essential, will the patient stand another 10 minutes or so to make the ultimate condition even more hopeful?" With this last proviso in mind it might almost be said that anyone can give an anaesthetic for a gastrectomy: it frequently needs the master for dental or throat or other cases that so often come under that surely-to-be-condemned term "minor operation."—I am, etc.,

London, W.1.

T. DE LACY WALKER.

### The Oxford Vaporizer in India

SIR.—Much has been written about the Oxford vaporizer already, but when the apparatus was sent to the tropical climate of India there was some doubt whether it would be satisfactory. Therefore, the apparatus was tested, to see if it would give satisfactory results in the extreme climate of a plains station. During the summer the maximum temperatures recorded last year were almost  $130^{\circ} F.$ , many Europeans dying of heat stroke, whereas in the winter the minimum temperatures are often between  $40^{\circ}$  and  $50^{\circ} F.$ , blankets and eiderdowns being needed at night. It has proved to work perfectly, and have the same advantages as in an English climate. This is after several trials with many methods (see notes and observations below).

There is one point on which to dwell, and that is the "premedication" of the apparatus itself, which cannot be satisfactory unless the climate is considered. If the apparatus is to be used as it was intended—i.e., an Oxford vaporizer No. 1 giving out definite percentages of ether vapour—then the mercury of the thermometer on the machine has to be within the maximum and minimum limits (t2 and t1).

In cold weather hot water is poured into the water chamber about 20 minutes before the operation list begins, by which time the mercury of the thermometer will be within the required limits. If the apparatus is allowed to cool—i.e., the mercury being below the t1 limit—then the percentage of ether delivered to the patient will be about two-thirds of the percentage registered by the machine (confirmed by private correspondence with Prof. R. R. Macintosh). During the hot weather cold water is poured into the water chamber about 20 minutes before the operations begin. The cold water must be really cold. If the water is tepid then the mercury of the thermometer will remain above the maximum limit—namely, the t2 mark: in these circumstances the machine will act as

an Oxford vaporizer No. 2 by delivering a 100% ether vapour. However, the patient's respirations drawing air through the ether chamber cause some heat loss and eventually the mercury will come down to the required limits necessary for the machine to act once again as an Oxford vaporizer No. 1.

### Observations

- (1) The machine functions satisfactorily in those parts of India in which cold water is available during the hot weather.
- (2) Its own advantages are still present in the Indian climate:
  - (a) By giving out a constant concentration of ether owing to the constant temperature, the depth of anaesthesia tends to be more constant, the ether concentration being adjusted according to the depth of anaesthesia of the patient.
  - (b) By delivering heated ether the heat loss by the patient is less.
  - (c) The machine is a very mobile compact unit.
  - (d) Oxygen and/or carbon dioxide can be administered also through the apparatus.
  - (e) Nitrous oxide may be given with the machine, either solely for anaesthesia or for induction before ether anaesthesia.
  - (f) The patient is not likely to become cyanosed because there is always a constant supply of air in each inhalation.
  - (g) Endotracheal anaesthesia may be performed very satisfactorily either for E.N.T. or general operations.
  - (h) Post-operative pulmonary complications, especially in "bad operation risks," tend not to occur. Warmed ether helps to avoid such complications.
  - (i) The vaporizer is a simple apparatus, and a relatively inexperienced anaesthetist, with a little tuition, soon administers a satisfactory anaesthesia.
  - (j) The vaporizer gives excellent results during and after operations of long duration—e.g., 4 hours.
  - (k) There is no difficulty in obtaining a deep ether anaesthesia with perfect relaxation. Very small quantities of ether are used, and there is little ether in the atmosphere of the operating theatre.
- (3) The Oxford vaporizer was used 245 times.
- (4) Highest official temperature recorded in the newspapers was  $117^{\circ} F.$
- (5) Highest temperature in the operating theatre was  $102^{\circ} F.$
- (6) Longest time vaporizer was used for one operation—4 hours.

I have to thank Col. A. Moffat, I.A.M.C., and Lieut.-Col. A. K. Ashworth, R.A.M.C., for permission to publish this note.—I am, etc.,

P. H. BLACKISTON,  
Captain, Indian Army Medical Corps.

### Cerebral Malaria

SIR.—In your issue for Dec. 25, 1943, which I have recently received, I note with interest Surg. Lieut. Sneddon's description of a fatal case of cerebral malaria (p. 814). That the staff of the hospital were ignorant of this disease seems fairly obvious, but as cases of this nature are becoming increasingly more common away from tropical areas I think that some criticism of the treatment received by the patient is indicated. To a number of us in Australia who have served with the armed Forces in New Guinea the inadequate treatment given to severe cases of malaria by practitioners on the mainland ignorant of this disease has always been a great worry.

The pathology of cerebral malaria is known to most, and it is quite obvious, as Surg. Lieut. Sneddon points out, that the aggregate of infected red cells in the cerebral capillaries must be removed as soon as possible. The case described is classical enough, but in the case of a man who had been at sea and whose movements had to be cancelled, cerebral malaria should surely have headed the list of possibilities, and a blood film should be placed on the same priority as lumbar puncture. If Field's stain is employed this only takes a few minutes.

The initial treatment is correct enough, but quinine dihydrochloride can be administered without the medium of an intravenous saline infusion. It is preferable to give not more than  $7\frac{1}{2}$  gr. at a time in 10 c.cm. distilled water. The injection is given slowly (taking, say, 15 minutes) through a small needle. This must be repeated in 6 hours, at the rate of 30 gr. daily, if the patient is unable to take the drug by mouth. Surg. Lieut. Sneddon does not mention any quinine given by the oral route. Experience after the fall of Rabaul showed us that oral quinine, if it could be forced into the stomach when there was no vomiting, was almost as good as intravenous quinine in cases of cerebral malaria, but more than 10 gr. daily are needed whatever route is employed.

Of course quinine haemoglobinuria must be watched for, and if this occurs atabrin must be given with increased fluids, intravenous or otherwise. The hesitation displayed by some practitioners in giving adequate doses of quinine in severe cases of malignant tertian malaria for fear of precipitating black-water fever is not warranted, at least in the south-west Pacific area. Whether or not this was the case in Surg. Lieut. Sneddon's patient is not disclosed. I feel certain that more quinine would have modified the prognosis of the case described.

My apology for this letter is that grave emergencies, whether medical or surgical, need a bold approach. The dictum of *primum non nocere* can well be replaced by "needs must when the devil drives."—I am, etc.,

Sydney, N.S.W.

C. LELEU.

### Treatment of Sciatica

SIR.—Sir Arthur Hurst, whose article on sciatica appeared on Dec. 18, 1943, could learn a great deal from a personal attack. His pronouncement that simple rest and confidence will easily cure in most cases is belied by medical experience. His "rational treatment" of rest for a month supported by pious hopes, then rest for another month supported by more pious hopes, and then, if no better, handing over to the neurosurgeon with, presumably, apology for pious hopes expressed, and eventual labelling as hysteric, hardly deserves to be termed "An Essay in Debunking," its conclusion providing rather the escape for the frustrated physician confessed by Hale White.

The great variety of treatments condemned by Sir Arthur Hurst implies not, as he believes, that they cure by suggestion but that they generally do not. Sciatica is a symptom, its causes are divergent and by no means completely understood. The patient in an exceptional case of my own experience, who had endured a plaster-of-Paris jacket, developed a sarcoma of the buttock five years later, followed by glandular sarcoma in the abdomen and the neck: repeated x rays had been entirely negative, but she never lost her pain. A premature pronouncement that the condition is a neurosis is likely to prove obstructive to thought by the doctor, with the temptation to accept an inactive course and to leave the patient to his fate. It is an unpleasant fate. Personal experience as a doctor and as a patient has taught me some points about sciatica.

1. Vibration is particularly unpleasant, whether it occurs in bus, train, or motor car, or merely from the heavy tread of a foot in the patient's room. This suggests that vibration may be an important causal factor where a position is long maintained (as in lorry or car driving with badly designed seat).

2. The patient tends to find a position that is comfortable and to maintain that position too exclusively for the good of his musculature; often the sciatica patient can only lie on one side or cannot lie on his back or prone with comfort. This pain-dodging factor continued over a long period of time with the general weakening of muscle from recumbency accounts for the "hysterical posture" of Sir Arthur Hurst's beliefs.

3. The emotional mind-disposition towards pain is *post hoc* not *propter hoc*. It is the natural consequence of unremitting pain. It is not the severity of pain but its tiresome prolongation which wears down the patient, a descent which is accentuated by the crippling effect of any upset of the pelvic skeletal structures, for it greatly handicaps any enterprise except reading. The patient is reduced to "listening in" to his pains. He finds himself compelled to shift his leg with tiresome frequency; even the pressure of one leg on the other is uncomfortable in acute cases. This is best relieved by a ring of bandaged wool between the knees, not by a pillow.

4. There are probably elements of muscular spasm, similar to the rectus protection of the acute appendix. Such a position as approximation of the soles of the feet is temporarily relieving, though difficult to maintain; no doubt it has a splinting effect. To hang the whole limb in a sheet to swing it just clear of its opposite member helps to give comfort.

5. General examination should be thorough; history carefully taken. Such factors as neoplasm, high uric acid in the blood, antral or prostatic infection, may be discovered. Blood count and blood sedimentation should be taken.

6. Muscles of back and limbs should be conserved as carefully as may be. The mattress should be firm and should not sag; the bed should be of adequate length.

Theoretically it is probable that pelvic and spinal strains, supported by inadequate muscles, are largely responsible for the origin

of sciatica, and it is possible that vibration accentuates this ill effect. Prolonged sitting, especially in a badly constructed or hard motor seat, seems to give rise to trouble. The upright position has sciatica as one of its penalties. On general principle of justice it is unfair to condemn the sciatic soldier as a malingerer without complete examination and the utmost certainty. It is pertinent to ask what pathology precedes the herniated disk. Sciatica commonly goes as it comes; we know not why. An ostrich-like pretence that it's all quite simple will not help us.—I am, etc.,

GEORGE H. ALABASTER, M.D., F.R.C.S.Ed.  
East London, C.P., South Africa.

### Ketosis in Children

SIR.—The observation of Dr. F. B. P. Evans (March 25, p. 432) on the prevalence of ketosis in children and the letter from Dr. George Bray (April 8, p. 503) prompt me to request again the courtesy of your columns.

You were kind enough to publish a letter of mine in the *Journal* of May 1, 1943, in which I drew attention to the frequent occurrence of ketosis in children below the age of 6 suffering from asthma. Several doctors have written to me describing their success in treating asthma in young children by diminishing fat intake and prescribing glucose drinks and alkagen granules.

It is interesting that Dr. Evans has confirmed my observation that ketosis frequently follows a period of nervous excitement, and it is my experience that an attack may be prevented by giving a child who has been unduly excited or has had some nervous strain glucose drinks and an alkali. An asthmatic attack is one of many symptoms a child may show, the most common being, as Dr. Evans points out, simple pyrexia up to 104° F. with nothing to be found on careful examination except acetone bodies in the urine. Another sign almost always present is pale stools. They may precede the onset of pyrexia, abdominal pain, vomiting, or asthma.

Apart from the acute cases there are many children suffering from what might be called the state of subacidosis. The history obtained is that the child is fretful and discontented, "girling," and loss of appetite are conspicuous. Often the child is disobedient, bad tempered, and the mother expresses fear that her child is becoming spoilt. The youngster may be brought to the doctor as a suspected case of threadworms, or the doctor may be asked if enlarged tonsils and adenoids could be causing the trouble. The child usually resents examination, clinging to the mother and crying lustily. The urine with the sodium nitroprusside test shows a definite blue colour but not the dark purple found in the acute cases. The change within a few days when a low-fat high-carbohydrate diet is given along with alkalis is most dramatic. As one parent put it: "Betty is a new child and her sweet little self again."

I cannot agree with Dr. Bray that these children are allergic to fats, etc. Such children can be given fats provided sufficient carbohydrates are taken at the same time—butter with jam, syrup, or honey. Fats need be excluded only during an acute attack, and it has never been my experience that acidosis occurs as soon as, say, bacon fat or milk is added to the diet. The relief he has obtained by injecting 3 to 5 m of adrenaline 1:1,000 is most likely due to its action in converting glycogen into glucose, in the same way as adrenaline may relieve hypoglycaemia due to an overdose of insulin.

War conditions may contribute to this upset in children, but my view is that it is one which in the past has been seldom recognized. How often in taking histories one is told that a patient as a child had a weak stomach, or bad frequent feverish attacks, or was difficult to "bring up." As Dr. Bray remarks, many of the sick headaches and migraine attacks of later life may start with acidosis in childhood. Here, I think, the psychological factor comes into prominence. A belief in the inferiority of some organ is instilled into the child as the result of frequent upsets, causing much alarm to the parents, which, in turn, is transmitted to the child. So in later life we have the asthmatic, the dyspeptic, the migrainous, etc.

May I suggest the routine examination of the child's urine for acetone? It can be done at the bedside if the doctor carries the following in his bag: 1-oz. bottle containing pulverized sodium nitroprusside 1 part, pulverized ammonium sulphate 20 parts

1 oz. liq. ammon. fortis; 1 test-tube. To half a test-tube of urine add half-inch of mixed crystals, shake well. Add half-inch of liq. ammon. fortis and allow to stand. A characteristic purple permanganate colour results if acetone or aceto-acetic acid, or both, are present (Lawrence, *Diabetic Life*). Another method is described by Mr. John Ingram in the *Journal of April 8* (p. 512).—I am, etc.,  
Edinburgh.

ALISTAIR G. CRUIKSHANK.

### Parodontal Disease

SIR.—I am afraid I cannot agree with the opinions Dr. E. Wilfred Fish (Dec. 4, 1943, p. 726) expresses, and think it most dangerous to hold such views. The least osteitis round the apex of a tooth or periodontitis anywhere round a tooth is sufficient to cause fifth-nerve irritation, and may thereby damage vision in so many ways that hardly a day passes without my having patients' jaws x-rayed. After forty years of ophthalmic practice I can safely say that a large portion of my income has been created by conservative dentists.—I am, etc.,

Johannesburg.

A. G. BRINTON.

### First Aid according to St. John's

SIR.—My surprise at the tone of Dr. Lampard's letter (April 8, p. 505) is only surpassed by its contents, and the kindest thing that can be said is that the writer has failed to appraise the true value of the St. John textbook. He begins by wondering how many doctors use splints (referred to as "little bits of wood") for rendering first aid to a fractured humerus. The answer is surely every sufficiently energetic doctor who appreciates the need for the correct immobilization of fractures, not only to prevent further aggravation of the injury but also to lessen the effects of shock. The remainder of his queries all lend themselves to similar simple explanations, and reference to any standard textbook will serve to confirm the correctness and modernity of the St. John teachings.

The St. John textbook resembles other medical and surgical books in that it indicates the diagnosis and treatment of an "average" case, and on the assumption that the "average" appliances and remedies are available. Treatment may have to be modified according to the needs and circumstances of each particular case, and using the basic training as his guide, the experienced "first-aider" adjusts his treatment accordingly. The basic suggested treatment may not always be 100% efficient, but it is the best that can be carried out in the circumstances, and what more can one expect of other medical or surgical treatment?

The "first-aider" is taught to work within reasonable limits because he is a layman and not medically trained. The so-called "rigid limits" and teachings have the approval of a large number of our most eminent colleagues, many of whom are intimately associated with the Order of St. John and its works. They, moreover, produce uniformity, and prevent the letting loose of a horde of amateur doctors on the general public. Furthermore, the standard textbook is used throughout the British Empire and is printed in many languages. Its scope therefore embraces injuries which may not be common in this country, although encountered in the Dominions and Colonies. The very little extra trouble in learning about them is thus surely worth while.

There seems to be a general conception that there is a new technique in first aid as a result of "blitz" or war conditions, but, strangely enough, no one seems to know quite what it is. It is true we have learned an uncertain amount about crush syndrome, of more specific war injuries like phosphorus burns, of methods of transport depending upon the use of specialized apparatus which would not normally be available to "first-aiders," and we have also been issued with varying instructions regarding the treatment of burns. The fact remains, however, that basically first aid has not altered at all, and that the so-called modern improvements are merely a rehash of the teachings of the standard textbooks. Arrangements exist for an interchange of first-aid information between the Order of St. John and the various interested Ministries, and one may rest assured that those responsible for the first-aid policy of the Order are fully alive to modern conditions and needs.

Finally, if Dr. Lampard really wishes to transport the Knights of St. John from the days of the Saracens to those of General Montgomery, I would suggest that he sends his constructive criticisms and ideas to the appropriate authorities. I have no doubt they will receive appreciative consideration.—I am, etc.,

London, S.E.1.

M. M. SCOTT.

SIR.—I was delighted to read Dr. Lampard's letter (April 8, p. 505), for first aid is so important, especially in wartime, that instead of being a matter of 8 lectures and an examination it should be a minor science—progressive and sound. Whereas most techniques have progressed during the last half-century St. John's has remained almost unchanged. The reason for this stagnation is that hospital surgeons have not been in the habit of inquiring: "Was the casualty in this condition when you found him?"

There is hardly a single treatment in the St. John textbook, with the exception of the famous treatment for bites from a rabid dog, which is satisfactory and which could not be improved upon. Even the large arm-sling and the standard method of lifting are inferior to some of the newer methods. I have interested myself in first aid ever since I took my first St. John class in 1912, and during this war I have spent 1 or 2 hours every evening with the 10 first-aid points, the 2 first-aid parties, and the Red Cross Detachment and the St. John Division over which I have control. The Red Cross and the St. John require lectures annually in the methods laid down in their textbooks in order that the members may gain certificates and be entitled to wear the prescribed uniform. Whenever I give these lectures I impress on the class that the methods I expound are for examination purposes only, and are not to be used on actual casualties. After the examination I and the class spend a few evenings revising the newer methods which common sense and experience have proved to be more satisfactory.—I am, etc.,

R. C. C. CLAY.

### Shock Treatment of Mental Disorder

SIR.—May I, without giving offence, say that your question on page 537 of the issue of April 15 is nonsensical! If terms such as "material cells, tissues, or secretions," which are objectively derived, are mingled in one question with terms that are subjectively derived, such as "a sane outlook," you necessarily get a question that is unanswerable because of its form. The two sets of terms together do not make up a problem; they merely make nonsense. Sir Henry Bashford's attempts to state a relation between "cells" and "thinking" necessarily fail for exactly the same reason. No one who had traced for himself the derivation of his various convictions and ideas would attempt to state a relation in this form.—I am, etc.,

Liverpool.

K. W. MONSARRAT.

### Marriage and Parenthood

SIR.—Dr. Edward Griffith (April 15, p. 540) makes a praiseworthy plea for the profession to adopt a more enlightened attitude towards the many special problems of marriage. While I whole-heartedly agree with his main thesis, I feel that his approach to the question of contraception needs amendment.

Contraceptive advice may very rarely have to be given to a couple before the birth of their first child, but it should not be given under such circumstances with the readiness which Dr. Griffith's letter would seem to suggest. There are many reasons for urging that the aim of the newly married couple should be the immediate establishment of a family.

Completely satisfying coitus is a difficult art, while its achievement is a *sine qua non* of a successful marriage. The bride and groom can learn much from their respective parents, from their doctors, and from a very extensive literature (among which, incidentally, the doctor should be ready to guide them, for its quality is widely varied). But in the last analysis they must be guided by their instincts. The instincts are a fully adequate guide provided that they are given free rein. It is only when they are subdued and repressed that they fail. Even assuming the perfect contraceptive, which would offer no

physical interference whatsoever, the fact that a contraceptive is being used, the fact that coitus is being practised for some aim short of its full natural purpose, means that psychologically there are barriers to the full play of the instincts. The childless couple which copulates but avoids pregnancy copulates half-heartedly, and will probably never learn to do otherwise. Once the art of intercourse has been mastered, and once the couple has attained the fulfilment of actual reproduction, then the complication of a contraceptive can be introduced without fear of disharmony.

The change from the single state to the married state is a tremendous one, involving a mass of difficult psychological adjustments as well as physical ones. If a couple passes through this stage—which takes many months for its completion—and remains a unit of two, then a whole series of fresh adjustments are required when it becomes a unit of three. It is infinitely easier and happier if the first child arrives during the adjustment period, when it fits immediately into its parents' life. Couples which become completely adjusted as units of two tend to shirk the difficulty of further adjustment, and to postpone the establishing of a family—sometimes until it is too late.

The artificial production of sterility is comparatively easy. The removal of a natural sterility can be most difficult. I am constantly being grieved by my inability to help cases of sterility which have been long-hidden and have come to light only when it is too late to hope to do much. The woman of 34 or so who has married, who has "cleverly" avoided pregnancy for five years, who has then spent five disappointed years seeking pregnancy and discovering that she is not fertile, and who then asks for help, is a much greater problem than she would have been had she discovered her sterility eight years earlier.

Against all these factors the excuses usually adduced for postponing the first child weigh very lightly indeed. Unless there is some pathological condition in one of the couple contraindicating parenthood, let us therefore, when asked for contraceptive advice by the newly married, attempt first with our best endeavours to readjust their sense of values and to persuade them to postpone, not the child but the Dutch cap. We shall do them a service which will be, eventually, deeply appreciated.—I am, etc.,

West Bromwich.

D. SAKLATVALA.

### Service Medicine

SIR,—Your correspondent of April 1 (p. 470) gives, in my opinion, a very one-sided and misleading view of medicine in the Forces. True it is that the civil front carries far heavier burdens, generally speaking, than the Services, and is worse off for doctors. But I have served for four years, under all conditions of medical work from M.I. room to hospital establishment, and including a tour over-seas, and have never found evidence of over-staffing. There was adequate work for all in ending to both out- and in-patient requirements; and your respondent has not referred to the preventive aspects of service medical duties, the continuous attention which must be given to sanitation and hygiene, particularly over-seas. Limitation of working hours has, in my experience, been due to efficient distribution of duties rather than to a superfluity of medical officers.

It is to be deprecated that such condemnatory remarks about one's brother-medical officers should have been presented for publication. In this respect I should say that it is not always possible in the Service to give every doctor, immediately at any rate, the type of work in which he is most experienced. I have definitely not met with cases of consultant positions held by men with inadequate qualifications. Even if a medical officer finds that he does not know enough to deal with a case himself, he has, in the R.A.F. anyway, always got ready access to specialist advice and full hospital facilities. Even over-seas this was always the case.

Your correspondent shows a complete antagonism to what he terms bureaucracy, but what I should term supervision and administration. For the efficient working of any organized medical service a certain amount of paper work is essential both at the time and for future reference, including permanent records. Such measures do not impede attention to the patient;

rather do they ensure it. Without properly filled medical documents it would be impossible to keep a check on the patient at a later date.

So long as a Service doctor enjoys the commissioned rank to which his qualifications and subsequent experience make him entitled, there seems no reason why he should resent being subject to confidential reports, like any other officer. Such reports on a medical man pass through medical channels.

I have never found any difficulty in obtaining or exchanging equipment, except when bad communications or shortage of supplies caused delay. Local supplies of drugs were never unobtainable. Mobile squadrons carry a more than adequate quantity of instruments, etc.

Far from being in the most browbeaten and the least organized branch, I have found that the Service medical officer, however junior, wields considerable power, and if he is in any way gainsaid he can readily seek the aid of his seniors, even if the case amounts to a revision of existing policy. Your correspondent, of course, does not reveal in which medical service he is employed, and my answers to his statements are largely based on my experience in the R.A.F. I consider that the excellent attention, both in preventive and curative medicine, given to Service personnel is a perfect example of "the community ideal of service for others."—I am, etc.,

E. HOPE LAMB,  
Squadron Leader, Royal Air Force.

## Obituary

DR. JOHN FREDERICK VENABLES died suddenly in London on March 31 at the age of 56. He was educated at Magdalen College School and Magdalen College, Oxford, and went on to Guy's Hospital for his clinical course. He graduated B.M., B.Ch. in 1913, proceeding D.M. in 1924. He served with the R.A.M.C. in Egypt during the last war, but was invalided home and became second in command of the Seale Hayne Military Hospital for functional nervous diseases. After the armistice Dr. Venables was in charge of a hospital for war neuroses under the Ministry of Pensions. In 1921 he went to join Sir Arthur Hurst again, as physician to the New Lodge Clinic at Ascot; when the clinic closed soon after the outbreak of the present war he rejoined the R.A.M.C., and reached the rank of temporary major. Increasingly frequent attacks of angina pectoris compelled him to resign his commission in June of last year, but in October he became a medical member of the first of the new pension tribunals.

The death occurred on April 8 at Thoraby, Wensleydale, of Dr. JOHN JAGGER PICKLES, fourth son of the late Dr. J. J. Pickles of Leeds. He was born in 1888 and graduated at Leeds University in 1912, serving in the last war and being wounded on the Somme. From 1919 to 1937 he was in practice in Leyburn, but retired in the latter year for reasons of ill-health. During the present war he pluckily returned to work, but finally broke down in health a year ago. He was a bachelor, and fond of country life and the natural history of the countryside. He joined the B.M.A. in 1919.

DR. WILLIAM EDWARD BENNETT, for 50 years M.O.H. at Otley in Yorkshire, died on April 10 at Knaresborough, aged 84. A native of Otley he studied medicine at Leeds and took the Scottish triple qualification in 1886. During his early days as a general practitioner in Wharfedale Dr. Bennett used to make his rounds on horseback. He had an absorbing concern for the welfare of the town and everyone in it. It has been said of him that he was the very pattern of the family doctor, diligent in everything except sending in his bill; and if he had once had people under his care he never lost interest in their progress. When he retired from strenuous private practice at the age of 60 it was merely to take up fresh work; for the next ten years he spent six out of every twelve months at sea as a ship surgeon; on his return from winter voyages he attended the Women's and Children's Hospital at Leeds and also assisted at a Barnsley hospital. To celebrate his jubilee as medical officer for Otley, past and present members of the local council and officials made him a presentation in recognition of his valuable service, which had changed the town so much from what it was in 1887. In 1940, at the age of 80, Dr. Bennett enrolled in the E.M.S. and was passed as fit for duty and appointed to an emergency hospital.

The Rev. JOHN COOK TENNANT, M.D., who died in Fife last year, was a man of much versatility. Born at St. Andrews 1860 he attended the Madras College and then took the A. degree, and a full theological course at St. Andrews, and after being licensed by the Church of Scotland went to charge in Australia. A complete change of attitude towards religion caused him to take up sheep farming, and a ranch became the centre of his activities for 18 years. Then at the age of 43 he returned to start life anew as a medical student in Edinburgh, graduating M.B., C.M. in 1908 and M.D. in 1910. He left Edinburgh for Melbourne and set up as a psychiatrist in Collins Street. In the last war he worked at various military hospitals, mainly among cases of "shell-shock." After the war he became a ship surgeon. During the last 15 years of his life Dr. Tennant underwent a profound spiritual change, the agnosticism and critical views of his earlier years being replaced by a simple faith.

The following medical men have recently died abroad: Dr. HENRY GRAY BARBOUR, professor of pharmacology at McGill University in 1921-3 and afterwards at Yale, aged 57; Dr. LOUIS LANCHEIRO WILSON, a notable pathologist and medical educationist at Rochester, Minnesota, aged 76; Col. ROY DENNIS, chief of the neuropsychiatric branch, U.S. Medical Department, aged 40, of coronary thrombosis; Dr. HANS WERNER BÜHLER, ophthalmologist at Geneva; Dr. M. CHIFOLIAU, senior surgeon to the Hôpital Saint-Louis, Paris; and Geh-Rat WALTHER KRUSE, bacteriologist and emeritus professor of hygiene at Bonn, Königsberg, and Leipzig, aged 79.

## Universities and Colleges

### UNIVERSITY OF GLASGOW

A graduation ceremony was held on April 15, when the following medical degrees were conferred:

M.D.—J. H. Lawson, Janet F. Morrison, J. P. Currie, A. M. Sutherland, W. L. Milligan.

The following prizes among others were awarded:

University Prize—Bellahouston Medal: G. H. Bell.

Special Class Prize—Surgery, Macleod Medal: J. B. Ritchie.

1 With honours. 2 With high commendation. 3 With commendation.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council held on April 13 with Sir Alfred Webb-Johnson, President, in the chair, the following elections were made to the Court of Examiners: Mr. Seymour Barling, re-elected for one year; Mr. Alan Perry, re-elected for two years; Mr. E. A. Crook, elected for three years. Brig. Ashley Daly and Dr. M. H. Jupe were elected Fellows under the Charter, which permits the Council to elect annually to the Fellowship, without examination, two members of twenty years' standing. The Jacksonian Prize for 1943 was not awarded on this occasion. The subject for the Jacksonian Prize for 1945 will be "Bone Grafting in Surgery: Its Indications, Methods, and Results." Votes of thanks were given to the President for the gift of a collection of engraved portraits, to Mr. G. H. Colt, F.R.C.S., for a mounted Brodie Medal, and to Mr. Richard C. Davis for a gift of money.

Diplomas in Child Health were granted, jointly with the Royal College of Physicians of London, to the following candidates:

T. J. Agius-Ferrante, Isobel C. Allardice, Evelyn A. Bishop M. Bojko-Uncar, Peniel M. E. Chiny, Norah H. C. Clark, Sheila Cochrane, J. W. Fletcher, Margaret D. Giles, Janet D. Gimson, Irene D. M. F. Castlow, E. Lewis, M. G. Philpott, Helen S. Standley, T. Stapleton, Pauline Wynne.

Three Hunterian Lectures will be given at the College (Lincoln's Inn Fields, W.C.) on Monday, Wednesday, and Friday, May 1, 3, and 5. All the lectures begin at 4 p.m. and are open to advanced students and medical practitioners.

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The following candidates, having satisfied the examiners, have been awarded the Diploma of the College:

Caroline D. Baugh, Marjorie Bryan, M. Dods, J. S. Hogg, E. C. Housden, D. Laito, Mary E. Long, Helen M. Mayer, Marjorie L. Penwill, J. R. F. Poppellwell.

### CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examination, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.&S.Glas.:

M. H. S. El Amroussi, S. B. Ballantine, G. W. Barker, Doris E. N. Bleasby, S. Datzel, R. E. McIl, Dunlop, J. W. Edmondson, L. M. G. Gussak, D. Headley, A. M. Herman, R. Keane, D. Munn, K. S. Mowatt, H. A. Munro, R. J. McClements, A. R. MacKinnon, D. Nathanson, A. C. Farnell, C. J. K. Piyso, K. A. Said, Abd El Monem El Sebeldi, L. I. Stirling.

M. Balint, M.D. Budapest, a graduate of a recognized foreign University, was also admitted a licentiate.

## The Services.

The *London Gazette* has announced the appointment as M.B.E. (Military Division) of Temp. Surg. Lieut. D. K. T. Wallace, R.N.V.R., for outstanding bravery and devotion to duty in tending the wounded during an air raid.

Col. W. K. Morrison, D.S.O., late R.A.M.C., Major (Temp. Lieut.-Col.) T. F. Briggs, and Capt. J. G. Pyper, R.A.M.C., have been mentioned in dispatches in recognition of gallant and distinguished services in Malak.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in the Middle East: Major-Gen. (Acting) W. H. Ogilvie; Brigs. (local) D. E. Bedford, G. MacDonald, and S. Smith, K.H.P.; Col. (Temp.) R. Murphy, C. Popham, O.B.E., and A. E. Richmond, O.B.E.; Col. (Acting) T. S. Law; Majors (Temp. Lieut.-Cols.) P. Carney, M.C., J. B. George, J. S. Jeffrey, C. A. Levy, N. MacLeod, J. E. Measham, J. S. Miller, R. W. Scott, A. P. Trimble, and H. L. Wallace; Capt. (Temp. Major) (Acting Lieut.-Col.) J. Pyle, M.C.; Capt. (Temp. Majors) K. G. A. Barlow, M.B.E., A. Crerar, D.S.O., M.C., G. C. Dansey-Browning, W. S. Gale, A. G. R. Lowdon, J. D. MacLennan, H. A. Palmer, L. S. Rogers, M.B.E., J. Urquhart, and C. E. van Rooyen; Capt. (Acting Major) R. S. Turner; Capt. K. MacK. Bell, E. L. Farrow, R. Fletcher, S. G. McK. Francis, S. T. Headley, T. M. Lennox, A. D. Morgan, P. A. Petrides, B. W. Powell, J. W. T. Pretsell, M.C., K. Simon, J. W. Spence, W. W. Willson, and G. Wilson, R.A.M.C.; Capt. (Temp. Major) C. W. Greene, Capt. V. Parkash, Subadar M. Y. Shah, Jemadar S. P. Redkar, Cdr (Assistant Surg., 1st Class) W. Bornshin, I.A.M.C.; Capt. H. Fine, R.C.A.M.C.

The *London Gazette* has announced the award of the D.S.C. to Temp. Surg. Lieut. E. O. Davies, R.N.V.R., for great courage and devotion to duty in caring for the wounded during landings at Salerno; and Temp. Surg. Lieut. J. A. Henderson, R.N.V.R., has been mentioned in dispatches for courage and skill in H.M.S. *Chanticleer* on convoy escort duty.

The Efficiency Decoration has been conferred upon the following officers of the Territorial Army: Col. J. Carver; Lieut.-Col. (Temp. Col.) J. T. McQuat, O.B.E.; Lieut.-Cols. F. A. Belam and T. A. S. Samuel, N.C.; Majors (Temp. Lieut.-Cols.) J. H. Dunn, J. B. S. Guy, W. A. Mackey, D. J. MacMyn, J. K. Steel, G. Sparrow, M.C., and G. D. Thompson, R.A.M.C.

The Order of the Red Star has been conferred upon Surg. Lieut. G. H. Murray, R.N.V.R., by the Presidium of the Supreme Council of the U.S.S.R. for services to the U.S.S.R.

The initials of Capt. (Temp. Major) A. G. R. Lowdon, R.A.M.C., are as now given and not as stated in the *London Gazette* of March 23, and in the *Journal* of April 1 (p. 475).

### CASUALTIES IN THE MEDICAL SERVICES

Killed.—War Subs. Capt. J. B. Ashmore, R.A.M.C.

Prisoners of war—Lieut. G. Blair; War Subs. Capt. F. E. Butterfield and C. D. Chilton, R.A.M.C.

## Medical Notes in Parliament

### Medical Officers at Military Prisons

Setting out on April 5 the progress made in implementing the recommendations concerning the Army, which were submitted by the Oliver Committee on Military Prisons and Detention Barracks, Sir JAMES GRIGG said that owing to the shortage of medical officers it was impossible at the present time to appoint a whole-time medical officer for each establishment. Steps had been taken to ensure that a medical officer was available at each establishment when required. At each of the five larger establishments one was attached for full-time duty. Sick quarters were now installed in all military prisons and detention barracks, except Aldershot. There the quarters should be completed shortly.

### Investigation of War Diseases

Sir Arthur MacNalty, who is Editor-in-Chief of the Official Medical History of the War, informs Mr. Willink that selected hospitals are co-operating fully in an investigation which is proceeding concerning any changes in types of disease that may be occurring during the war as compared with a typical peace year, and that the Service Departments are obtaining medical data relative to the campaigns in all theatres of war. Statistics concerning infectious diseases are being furnished by the Registrar-General.

### Germany's Chemical Industry

In the House of Lords on April 18 Lord VANSITTART asked the Government whether, in view of the paramount necessity for permanently preventing the manufacture of all explosives in Germany after the war, they would appoint a committee of scientists to prepare a practical and efficacious scheme, with particular regard to the control or elimination of Germany's nitrate and hydrogenation plants.

Lord HORDER, speaking as a doctor, said it was clear that the Nazis' long and devilish preparation for an all-out war included more things than killing human beings by explosives: it included preventing the cure of human beings who fell sick of disease. For a long time before the war the Nazis deliberately cut down to starvation-point the manufacture by other countries of chemical substances vital to the pursuit of medical science and treatment. He referred to two essential drugs. The first was suramin, which the Nazis—surely with their tongue in their cheek—called Germanin. They prevented countries other than their own from using it. It was made by Bayer as the result of a secret process, and was of great use in the treatment of sleeping sickness. Still more important was the synthetic drug called atabrin, the equivalent of quinine. This was also a Bayer product. Both the constitution and the mode of preparation were kept secret for a long time, and the supplies outside Germany were very strictly limited.

At the outbreak of war, of course, these supplies ceased. No doubt we relied on the natural product, quinine, obtainable in quite large amounts at that time from the Netherlands East Indies. When that supply failed us we were caught out very badly. To what degree we were caught out only those responsible for the health of the armed Forces and of our people in the Dominions and particularly in India, and for the treatment of hundreds of thousands of cases of malaria, really knew, and this in spite of the quite valiant efforts which our own big chemical industries had made to help us.

It was clear, therefore, that a full inquiry by expert chemists should be undertaken into the whole field of synthetic chemical industry in Germany. Then, in conjunction with our allies and political experts, some plan should be devised whereby the manufacture of explosives in Germany could be entirely prevented, and a strict lien over and control of essential drugs by Germany ended.

Lord CHERWELL, replying for the Government, agreed that if we could prevent Germany from making synthetic nitrates we could prevent her making war—in the present state of knowledge. Nitrogen, however, was the essential element in proteins, which were necessary for food. In a modern world we had very largely replaced the bacteria in the roots of certain plants capable of fixing nitrogen and putting it back into the soil by the synthetic fertilizer. The difficulty was that if we stopped Germany making synthetic nitrate or ammonia there would be difficulty in getting fertilizers for Central Europe. Every effort should be and was being made to find out if there was a way of circumventing this difficulty. The same applied to the question of hydrogenation. Lord Horder's statement that the Germans had got exclusive control of certain drugs, and that when these supplies were cut off we were left in a bad way, was perfectly true. That was the reverse side of the medal, and it implied that we ought to make sure that we had sources of these drugs rather than stop the Germans making them. These questions required study and consultation, and various committees had been considering them and had recommended that more scientists should be invited to join in their investigation. We could not decide these matters alone; we had first to form views of our own and then discuss them with our allies. The Government agreed that the time had come to extend the participation of scientists in these questions, and proposed to invite a greater number of professional scientists and experts to take part in the deliberations. The more questionable proposals also of supervising German research would not be forgotten.

### Issue of Questionary and White Paper

On April 18 Sir E. GRAHAM-LITTLE asked the Minister of Health whether he had co-operated with the B.M.A. in the issue of a questionnaire to registered medical practitioners, otherwise than by supplying, without charge, copies of the White Paper to accompany it; what was the number of copies so supplied; at what cost and to what account was it debited; and whether he was consulted in the preparation of the questionnaire or the procedure of its distribution. Mr. WILLINK: It was, quite properly, never suggested that I should participate in any way in the preparation or issue of this questionnaire, which was entirely a matter for the B.M.A. With regard to the copies of the White Paper I decided that in view of the obvious importance of the Government's proposals to the individual doctor it would be helpful if I supplied a copy of it to

all practitioners in this country and in the Forces. The Association kindly undertook the distribution of these copies for me and, as a matter of convenience, distributed them with their own questionnaire and other documents. A total of 51,200 copies was involved, at the approximate cost of £950, which will be borne on the vote of the Stationery Office.

### Diphtheria Immunization and Notification

On April 18 Mr. ALFRED EDWARDS asked the Minister of Health what was his estimate of the number of children under 5 and between 5 and 15, who were inoculated against diphtheria down to the end of 1943; and if he would devise a method for removing from these records all children who reached 15 in 1940, 1941, and 1942. Mr. WILLINK said that the numbers of children inoculated against diphtheria in a given period by local authority arrangements were not estimates but figures supplied by the authorities of the numbers of children immunized in each six-monthly period. The totals of figures from January, 1940, to December, 1943 (the last yearly returns being not yet quite complete) were approximately 1,680,000 children under 5, and 3,136,000 between 5 and 15 at the date of immunization. The suggestion in the last part of the question would be very laborious to carry out, and he did not feel justified in adopting it.

## Medical News

Dr. T. L. Hardy will deliver the Croonian Lectures before the Royal College of Physicians of London on Tuesday, May 9, and Thursday, May 11, at 4 p.m. Subject: "Order and Disorder in the Large Intestine."

The mass miniature radiography unit which is being set up by the Leeds Corporation to aid the early detection of tuberculosis will have its headquarters in St. James's Hospital, where rooms and offices are now being prepared. When in full operation the unit whose personnel consists of a medical director and assistant, organizing secretary, and a team of eight radiographers, marshalls, and clerks, will visit factories in Leeds and the West Riding.

The London Hospitals Street Collections Central Committee announces that Hospitals' Day will be held on Tuesday, May 9. Suggestions and offers of service will be gratefully welcomed by the chairman, Lord Luke, at 36, Kingsway, W.C.2.

Six illustrated lectures on the historical background to modern medicine will be given by Mr. Douglas Guthrie, F.R.C.S., at the School of Medicine, Surgeons' Hall, Edinburgh, on Mondays and Thursdays, May 8, 11, 15, 18, 22, and 25 at 4 p.m. each day. The course is open to all students and medical practitioners.

A meeting of the Association of Surgeons of Great Britain and Ireland will take place on Tuesday, May 9, at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C. The following subjects will be discussed: caisson disease in joints; surgery of varicose veins; benign hypertrophy of the prostate.

At the annual meeting of the Westminster Hospital Ladies Association to be held in the Queen Mary Nurses' Home (entrance in Page Street) on Thursday, May 11, at 3 p.m., Mr. E. Roe Carling, F.R.C.S., will speak on "Journey to Moscow."

The Minister of Health has augmented the Ministry's staff responsible for visiting and advising hospitals on the best methods of preparing, cooking, and serving meals to patients and staff by the appointment of two women dietitians, Miss H. G. Cairney, M.B.E. and Miss M. R. Muriel. Miss Cairney, who holds a Dietetic Diploma, was from the outbreak of war until her present appointment, sister-in-charge at the L.C.C. diabetic unit at Hutton School, Brentwood. Miss Muriel was previously with the Ministry of Food part of her work was to report on hospital feeding, and she carried out surveys at several large hospitals. Since the setting up of the Emergency Hospital Scheme the Ministry of Health has been responsible for the treatment and care of large numbers of hospital patients. To assist in dealing with catering problems, it appointed Capt. J. Fraser, an expert in catering and kitchen equipment, since after the war started. He has visited over 300 hospitals, and wherever necessary, has made suggestions for improving the standard and quality of meals. Medical officers specializing in nutrition questions have also inspected emergency hospitals in many parts of the country. The advisory services of this special staff will be available to all types of hospitals—municipal and voluntary, as well as fever hospitals and tuberculosis sanatoria. So far as possible, they will cover the whole field of hospital catering—purchase of foodstuffs, choice of menus and diets, and the preparation, cooking, and serving of meals. In 1942 the Ministry issued for the guidance of hospital catering staffs a booklet called *Wartime Feeding in Hospitals*.

maintaining specimen diets and menus. The King Edward Hospital and recently appointed an advisory dietitian to assist voluntary hospitals in Greater London on dietary questions. Arrangements have been made to co-ordinate the work so that the Ministry's advisory service does not overlap with the activities of the Fund.

The preliminary programme for the seventy-fifth annual meeting of the Canadian Medical Association, to be held in Toronto from May 22 to 26, is published in the March number of the *C.M.A. Journal*. The president-elect is Dr. Harris McPhedran. A series of round-table conferences has been arranged for two of the mornings, followed by sessional meetings in the afternoons. At the first of the general sessions the outgoing president, Dr. D. Slater Lewis, of Montreal, will give his valedictory address, and the last general session will be devoted to a discussion on health insurance and allied problems.

The council of Epsom College will shortly proceed to award St. Anne's scholarships to girls attending Church of England schools. Candidates must be fully 9 and under 16 years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected. Forms of application can be had from the secretary's office, Epsom College, Surrey, and must be sent in by May 12.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In *England and Wales* during the week the incidence of infectious diseases fell sharply. The decreases over the previous week in the notifications for the following diseases were: whooping-cough 583, scarlet fever 361, measles 300, acute pneumonia 274, diphtheria 170, dysentery 59.

The lowered incidence was general throughout the country. For scarlet fever London reported 54 cases fewer than last week, Yorks West Riding 43 fewer, and Lancashire 38 fewer; for diphtheria Yorks West Riding and Lancashire reported 34 and 25 fewer cases respectively; for whooping-cough Lancashire's notifications fell by 74, those for Yorks West Riding by 50, and those for Essex by 62. The fall in measles was mainly in the north; in the south the incidence went up slightly; Lancashire reported 131 fewer cases than last week, Essex 81, and Durham 55.

The only fresh outbreak of dysentery during the week was in Suffolk, Deben R.D., 16. The largest returns were those of London 48, Surrey 37, Lancashire 36, Cheshire 20.

In *Scotland* notifications of measles were 167 fewer than last week, diphtheria 50, scarlet fever 48, acute pneumonia 39, whooping-cough 27, and cerebrospinal fever 21. The incidence of dysentery rose by 17 cases, the chief centres of infection being Lanark County 30, Dundee 14, Edinburgh 13, Dumfries County 13.

In *Eire* measles notifications were 100 fewer than last week, whooping-cough 64, and diphtheria 17. 11 cases of typhoid were reported from Tipperary, Roscrea No. 1 R.D.

In *Northern Ireland* the notifications of diphtheria rose from 30 to 45; 15 of the cases were notified in Londonderry C.B.

### Quarterly Returns for England and Wales

The returns of the Registrar-General for the December quarter of 1943 show that the birth rate at 15.4 per 1,000 was the highest for a fourth quarter since 1930, the average for the five preceding December quarters being 13.6. Infant mortality was 51 per 1,000 live births, 3 below the average of the ten preceding fourth quarters. The general death rate was 14.6 per 1,000, this rate being 3.6 above that for the corresponding quarter of 1942 and 2.5 above the five-year average. The decline from the high marriage rate during the first war years continued, and the rate—13.3 per 1,000—was the lowest ever recorded during the fourth quarter.

**Returns for the Year.**—The provisional returns for the year are included in the returns. The birth rate was 16.5 per 1,000, and was the lowest rate ever recorded, being 2 below that of 1942, the previous lowest. The general death rate was 12.1 per 1,000, and was 0.5 above that for 1942 but 0.8 below that for 1941. The marriage rate was 14.3 per 1,000, the lowest recorded since 1926.

### Week Ending April 15

The returns of the notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,870, whooping-cough 1,865, diphtheria 616, measles 2,578, acute pneumonia 983, cerebrospinal fever 96, dysentery 179, smallpox 1, paratyphoid 2, typhoid 5.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 8.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1944					1943 (Corresponding Week)

\* Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

## Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Alitology Westcent*, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 3353. TELEGRAMS: *Articulate Westcent*, London.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent*, London.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

### ANY QUESTIONS?

#### Fluid Intake and Toxaemia of Pregnancy

**Q.**—Patients who suffer from toxaemia of pregnancy are often advised to increase their fluid intake and to eliminate protein from the diet. Water retention plays an important part in the causation of peripheral oedema and of eclampsia (oedema of the brain). The level of plasma proteins is depressed. Would it therefore not be wiser to keep the fluid intake at a low level and not to restrict the protein content in the diet?

**A.**—There is much evidence in favour of the view that water retention plays an important part in the causation of eclampsia. There is, however, no general agreement regarding the cause of this retention, or as to whether the plasma proteins are lowered in eclampsia. It would seem advisable to limit fluid intake in pregnancy rather than increase it, as has been generally advised in the past, and many obstetricians now favour this course. It seems reasonable, too, in view of the fact that in established pre-eclamptic toxæmia with oedema, fluid and salt restriction is usual, in addition to rest to reduce the blood pressure. It is doubtful, too, whether protein restriction is beneficial in established toxæmias, especially in view of recent work on the part played by certain proteins and amino-acids derived from them in protecting the liver against necrotic changes.

#### Osteo-arthritis of Hip

**Q.**—Is there any form of treatment with which there is a reasonable hope of success in relieving osteo-arthritis of the hip—especially the pain of this complaint? Is gold treatment of any value? I see it is recommended for rheumatoid arthritis.

**A.**—Without a good deal more information, including x-ray evidence, this question cannot be answered satisfactorily. In some cases a calliper splint to put the joint at rest by separating the articular surfaces is desirable; in others, especially with severe pain, arthrodesis may be indicated. Good results have been obtained by injecting novocain saline in the vicinity of the joint, and lipiodol (now unobtainable, but similar preparations can be had) has been used with success; a certain amount of care and skill is required for a good result with this method. Apart from these methods ultra-short-wave diathermy sometimes gives relief but not always, and the same applies to deep x rays; either requires to be administered by someone with expert knowledge of the method. The usual analgesics may be employed, remembering always the danger of habit formation with many drugs of this kind in such a chronic condition. Gold treatment is absolutely useless in osteo-arthritis.

#### - Sawdust and Lung Disease

**Q.**—The manager of the export department of a firm of manufacturing pharmaceutical chemists tells me that an abnormally large number of men in the packing section of his department suffer from bronchial disorders, and that the men attribute this high incidence to the sawdust used in the packing. This dust is stamped down in the process of packing, and much of it flies about in the air surrounding the packers. Three cases lately mentioned by the manager as occurring among these packers were of bronchitis, asthma, and nicoplasm of bronchus respectively. The "*British Encyclopaedia of Medical Practice*" says that sawdust is one of the dusts whose liability to produce pneumoconiosis is unproved. Can you give any opinion about the desirability and the best, preferably unobtrusive, methods of preventing inhalation of the sawdust?

**A.**—Wood dust, when inhaled, irritates the upper respiratory passages, and the incidence of bronchitis among workers engaged in woodworking occupations which expose them to dust is somewhat in excess of the average. There is no evidence that pneumoconiosis or neoplasm of the bronchus is caused directly by wood dust. With sawdust of the soft woods, which are those likely to be used for packing bottles, the action on the respiratory passages is a physical

one, producing irritation by the rough surfaces of the particles, symptoms of chronic irritation and inflammation of the pharynx, larynx, trachea, and upper bronchi may be caused in susceptible persons. Dust of hard woods, such as beech, mahogany, and oak, is usually of smaller particle sizes and the deeper bronchi are affected. Certain woods, such as teak, are well known to cause severe symptoms in persons specially susceptible to them, but these woods are unlikely to be used as packing material. The possible presence of mould fungi in the wood may be kept in mind as a source of pulmonary trouble if sawdust from unsound wood or packing material which has been allowed to become damp is used. Apart from the provision of localized exhaust draught to remove the finer dust in the process of handling, which is probably the most effective in the circumstances, the wearing of a simple type of respirator would give a considerable measure of protection from the coarser dust. A suitable respirator could be constructed of a light wire frame with a few layers of gauze and worn over the nose and mouth; such respirators are available on the market.

#### Units of Penicillin

**Q.**—What are the units in use in the dosage of penicillin? American writers talk about doses of 25,000 units, and, in a course of treatment for early syphilis, a total of 1,200,000 units. Are these units the same as the "Oxford units"?

**A.**—Yes. The U.S.A. has adopted the Oxford unit, and standard preparation of penicillin provided from Oxford has been used for the assay of their products. This unit is a quantity which cannot accurately be defined in terms of biological effect; as in the case of so many other therapeutic agents which also cannot be weighed or otherwise measured, it can be expressed only as the activity contained in a given weight of a standard. While penicillin production is controlled as it is at present, the unit will remain reasonably constant quantity, and doses as stated in the present American and English literature can be taken to mean the same thing.

#### Sulphonamides and Fluid Intake

**Q.**—In the Medical Research Council War Memorandum No. 10 "Medical Use of Sulphonamides," pp. 40-1 (prevention and treatment of anuria, haematuria, etc.), it is advised to give about 5 pints of fluid in 24 hours to an adult to maintain a large urinary output of 2½ pints in 24 hours, and to perform cystoscopy if urinary output of 17 oz. persists for 24 hours; and on p. 14 it is advised to give sodium cit. gr. 20 and sod. bicarb. gr. 20 with the tablets. In the case of children, should the fluid intake, urinary output, and indication for cystoscopy and dosage of alkali given be calculated according to age of child and "quantity of urine passed by children daily" according to the table ("Clinical Methods," Hutchison and Rainey pp. 319 and 320) thus:

	Optimum Fluid Intake	Optimum Urinary Output	Dangerous Urinary Output	Dose of Alkali
If for adult ..	100 oz.	50 oz.	17 oz.	Sod. bic., sod. cit. 50 gr. 20
These ? for child :				
Aged 2 years ..	20 oz.	? 10 oz.	? 3 oz.	? Sod. bic., sod. cit. 50 gr. 3
Aged 4 years ..	26 oz.	? 13 oz.	? 4½ oz.	? Sod. bic., sod. cit. 50 gr. 5
Aged 8 years ..	40 oz.	? 20 oz.	? 7 oz.	? Sod. bic., sod. cit. 50 gr. 8

Are the amounts I have marked "?" the correct amounts to maintain to avoid toxic urinary reactions with sulphonamide treatment particularly with sulphathiazole?

**A.**—This question omits one essential factor which cannot be left out of account if it is desired to reduce the matter to absolute figures. This is the dosage of the drug. Granting, as stated in the authority quoted, that a full adult daily dose—say 6 g.—of the drug can be kept in solution in spite of acetylation provided that the daily output of urine be not less than 50 oz., then half that dose of the drug will call for a daily output of 25 oz. What matters, in fact, is the concentration of the drug in the urine. The dosage of alkali suggested appears satisfactory: the figure for "dangerous urinary output" may be calculated from the optimum, as has been done in the question.

#### Pituitrin for Herpes Zoster

**Q.**—The severe pain of herpes zoster (in my experience of 100 cases) is relieved in less than an hour by a hypodermic injection of pituitrin, but in neither case was the later and severe after-pain relieved. How does the pituitrin act? How was its action discovered? Is there any satisfactory remedy for the after-pain in these cases? I have heard of other cases relieved in the same way, but have personal experience only of two.

**A.**—The pituitary (posterior lobe) extract acts by lessening exudation from the skin capillaries, and so diminishing the tension which is the cause of the pain. Its action in diminishing exudation and

sedema, such as follows the application of mustard oil to the conjunctiva, or the subcutaneous injection of paraphenylenediamine, was demonstrated by L. T. Poulsen (*Arch. exp. Pathol. Pharmacol.*, 1927, 120, 120). The after-pain can be dealt with only by the usual analgesics such as aspirin, pethidine, or morphine.

### Miners' Nystagmus

**Q.**—It is widely accepted that the illumination provided at the coal-face in coal mines with the hand-lamps at present in use is not sufficient to maintain foveal vision throughout the "shift"; and that this is the chief aetiological factor in the production of miners' nystagmus. In an annotation in the "B.M.J." of March 4, 1944, it is stated that "foveal vision could be called into play in low intensities of illumination only if the light used were red in colour." If the coal face reflected, and pit dust absorbed, red light equally with white light, am I right in assuming that advantage might result from altering the present candle-power hand lamps from white to red light?

**A.**—It is possible that red light might be advantageous in the pit, though the coal face is not by any means identical with a luminous body of low intensity. What is more problematic is the role of foveal vision in mining, which is hardly "fine work" in the ophthalmic sense. Investigations during the past 20 years have tended to emphasize the psychological nature of miners' nystagmus, and little importance is now attached to low illumination as an aetiological factor.

### INCOME TAX

#### Expenses

E. V. asks what claims for professional expenses are recognized by the income tax authorities.

\* It is not possible to give a complete list here. In general the expenses that can be set against the gross receipts of a practice are those which can reasonably be said to be incurred in the carrying on of the practice and not for the benefit of the practitioner—e.g., cost of instruments and drugs. The practical difficulty is that a large proportion of expenses serve both purposes and have to be divided—e.g., rent and rates, cost of servants, telephone, car, etc. There is no clear guide to such a division; reason and common sense applied to the actual facts usually indicate the line fairly well. Expenses to be deducted by an assistant from salary are restricted by the requirement that they shall be necessarily incurred in the course of the employment; this renders ineligible professional subscriptions (unless membership of the Association is a condition of the employment) and the cost of travel between home and the place of work.

#### Annuity Payable by Insurance Company

A. P. wishes to know his position in respect of an annuity starting with a guaranteed period of  $\frac{1}{2}$  years whether he lives or dies.

\* If there is a single contract providing for a fixed payment for  $\frac{1}{2}$  years followed by an annuity terminating at death, the position is, in our opinion, at least doubtful. But a contract for a fixed period would apparently carry income-tax liability only as regards the element of interest in the payments made. Possibly what is contemplated is two separate contracts—one for a fixed term and another for life coming into operation as at the end of that period. A difficult question of law is involved, and the insurance company might be asked if they can guarantee their opinion.

#### Wife takes over Husband's Practice

M. M. has been in panel practice for many years, and following on the death of her husband has taken over his practice and added it to her own. Is this to be regarded as a new practice so far as M. M. is concerned?

\* Yes. M. M.'s liability will be based on (a) the profits of her old practice for the previous year plus (b) the profits of the husband's practice on the current year's basis, until she has held it long enough for the previous year's basis to operate for both.

#### Appointments: Travelling Expenses

"ERSILON" is employed by the E.M.S. as a full-time physician, but holds two honorary appointments in addition. He has to travel to the hospitals concerned, but has been refused a deduction for the cost of maintaining a car for the travelling.

\* This is legally correct. Where several appointments are held, the emoluments being assessed under Schedule E, the expense of travelling to the place where the duties are performed has been held by the courts not to be "incurred wholly, exclusively, and necessarily in the performance of the duties of the office."

#### Correction

The reply to "J. F." published on Feb. 19 as the first item on page 278 contained a clerical error: the figure at the end should be £30, not £50.

## LETTERS, NOTES, ETC.

### Strychnine and Field of Vision

Mr. H. M. TRAQUAIR, F.R.C.S. (Edinburgh), writes: On page 207 of the *Journal* of Feb. 5 it is stated that strychnine "causes a measurable increase in the field of vision." This statement appears in textbooks of pharmacology, but is based not on recent research but on observations dating from the work of von Hippel in 1873, followed by others. The evidence is contradictory and inconsistent, and one writer at least was entirely sceptical; certainly some of it is completely incredible. Is not this an example of the repetition of statements without proper scrutiny or criticism? It is difficult to believe that any drug can "increase" the field of vision in whatever sense the word "increase" may be used.

### High Birth Weights

Dr. FRANK CROSBIE (Ealing) writes: The expert who dealt with this question (April 8, p. 510) might be interested to know that on Dec. 10, 1927, my wife gave birth to male twins. G. weighed 7 lb. 6 oz., A. weighed 8 lb. 4 oz., a combined weight of 5 oz. more than the case to which he refers. Both are now Dartmouth cadets, G. weighing 11 st. 2 lb., height 5 ft. 9½ in., A. 9 st. 10½ lb., 5 ft. 8½ in.

### Excessive Sweating

Dr. A. J. AMBROSE (Paignton, Devon) writes: Your answers in the "Any Questions?" section (March 18, p. 412) on excessive local sweating will not satisfy many dermatologists nor the R.A.F. officer who is the victim of this distressing complaint. Like the Frenchman who, when asked on a cross-channel steamer if he had lunched—I would say, "Au contraire" to your advice to avoid x rays. Roxburgh in *Common Skin Diseases* says that no local treatment can cure, and that the usual practice is to give 3/4 pastille dose once a month until the condition is nearly cured, stopping short of cure so as to avoid the danger of producing too dry a skin. I agree with you that this great danger must be avoided, and it will be avoided if the work is carried out by an expert radiologist, especially if he is a dermatologist as well. If, however, the R.A.F. officer is nervous of trying 3/4 pastille dose, then he might get a good result with 1/4 pastille dose at weekly intervals. In addition to the excellent suggestion of bathing with hot water, R.A.F. might like to try acid. salicyl. gr. 10, pulv. alum. 1/2 oz., pulv. chalk 1/2 oz.; or acid. salicyl. 3%, acid. borie, 10%, French chalk ad 100%; or alum gr. 48, liq. formaldehyd. n 24, lanette wax gr. 33½, ung. acid borie gr. 142½, ung. zinc. ox. gr. 234. Light open-weave underclothing—and he should be advised not to take drugs such as atropine, or belladonna internally, as these are useless.

### Conditions in Detention Barracks

Dr. F. ALLEN writes from Poona: I have often wondered why prison and detention barracks, etc., in the British Isles do not follow the Indian example of having medical superintendents or governors or wardens or whatever name sounds best. I have been a jail superintendent and also jail M.O. for a combined period of nearly 10 years with breaks. The medical superintendent can so easily spot the men who are ill and is in a better position to deal with the malingers. I endeavoured always to admit a man or woman to hospital before he or she fell ill. I could vary the jail or individual diets to suit the case. I was working on my health statistics, but recall to military duty spoilt the sequence. I am all for a medical superintendent in the interests of humanity and of the prisoners, and I believe it is also to the benefit of the State.

### Breathing Exercises

Dr. L. SHELTON (Harlesden, N.W.10) writes: Some years ago, while acting as first assistant to Mr. Radcliffe (late surgeon E.N.T. Dept., Queen's Hospital for Children, Hackney) I noted that numerous children who had had their tonsils and adenoids removed still breathed badly—they were, in fact, still bad mouth-breathers. I suggested that these youngsters be taught to breathe correctly and that a skilled teacher be appointed with this object in view. Mr. Radcliffe agreed. I note now that most hospitals have skilled teachers who are doing excellent work in this field. Many mothers have, however, complained to me of the time wasted in travelling to hospital, so I venture to suggest that this work be undertaken at schools. The "war effort" would thus be helped (mothers have to have time off from work) and no schooling would be lost to the children.

### Detecting Trichomonas vaginalis

Dr. R. E. REWELL (Coulson, Surrey) writes: Under the heading of "Any Questions?" on April 8 I see you state that the *Trichomonas vaginalis* "can be detected by examination of a fresh specimen with a dark-ground microscope." This phrase seems to me to be unfortunate, as those inexperienced in the examination of discharges for

the presence of this organism may be led to suppose that the elaborate set-up for producing dark-ground illumination (as in the search for *Treponema pallidum*) is required. In fact, all that is required is that the condenser of the microscope be racked well down so as to produce a darkened background, just as is done during the enumeration of blood cells. A wet preparation of the fresh material is made, warmed for a few moments, and then examined with the ordinary 2/3-in. and 1/6-in. objectives. The organisms, with their pear-shaped bodies, anterior flagellae, and lateral undulating membranes, are easily seen among the immobile pus and epithelial cells of the vaginal discharge. I have no experience of searching for them in the male, but feel that they could be readily distinguished from spermatozoa by the most inexperienced. No other organism resembling them is likely to be found in the vagina or urethra. I feel that your phrase should be modified, as otherwise specimens may be sent long distances to laboratories equipped with dark-ground apparatus instead of being examined in the consulting-room, a thing anyone can do who still retains the microscope of his student days. The *Trichomonas vaginalis* is sure to die *in transit*, and then the examination is wasted.

#### Coincident Inflammation of the Hip-joint in Two Children

Dr. C. LL. LANDER (Maiden Newton, Dorset) writes: Two children, a girl of 5 and a boy of 3½, went to a tea-party in the village where they live at which a considerable number of children were present. Three weeks later they were seized with symptoms pointing strongly to acute inflammation of the hip-joint (infective osteomyelitis). First, the girl, who complained of pain in the left knee. She had a temperature of 103°, and lay with the thigh abducted and semiflexed. Any movement was excessively painful, the whole pelvis moving with the thigh en bloc when movement of the joint was attempted. Two days later the boy presented similar symptoms except that there was no pain referred to the knee. I treated both with sulphanilamide 0.25 g. tablets. The girl, owing to inefficient nursing, took only one tablet and parts of two others on the first day, but was decidedly improved thereby; six more tablets on the second day relieved the symptoms entirely; a further dose of four tablets was given on the third day. The boy had six tablets on the first day, followed by four on the second and third days. All pain and fixation of the joint had by then disappeared, and it was difficult to keep the child in bed any longer. In fact the parents gave me a broad hint that further attendance from me was hardly called for. These cases are unique in my experience, first, because of the apparently common source of infection and, secondly, on account of the dramatic way in which the symptoms completely disappeared.

#### Two Suggestions in Clinical Examination

Mr. K. WILSON JAMES, F.R.C.S.Ed., sends the following notes from Kingston, Jamaica: (1) *A Percussion Test in Acute Lower Abdominal Conditions*.—As an aid in the differential diagnosis of lower abdominal conditions this simple test is sometimes very useful. It consists in lightly percussing over certain areas and asking the patient to state the point of maximum pain. For example, the left hand is placed on the lower abdomen with the index and middle fingers separated to form a V. The tip of the index finger is made to rest over the internal inguinal ring and that of the middle finger over McBurney's point. On percussing, the site of maximum pain in acute adnexal conditions will be found to be over the internal ring, whereas it will usually be in the region of McBurney's point in acute appendicitis. (2) *A Three-finger Examination in Obscure Pelvic Cases*.—With the patient in left lateral, Syn's, or dorsal position as may be found most suitable, the index and middle fingers are introduced into the vagina and the lubricated ring finger into the rectum. The thumb then rests upon the pubis and the little finger upon the perineum. Thus the whole hand assumes a natural position, and an extremely thorough bimanual examination of the pelvis is possible with the aid of the other hand. There is the feeling as if the whole hand is inside the pelvis, and this manoeuvre is worth trying in difficult pelvic examinations and in obscure cases.

#### Swallowed Plastic Button undetected by X Rays

Dr. J. A. STEPHENS (Kirkburton) writes: On Nov. 29, 1943, a rather worried mother brought her baby, aged 7 months, to see me on account of the following circumstances. That morning on going to look at the child in his pram in the garden she noticed that the second button of his woollen cardigan was missing. She had noticed the child sucking this particular button, which was attached by wool, on a few occasions. She hunted high and low for the missing button but failed to find it, and assumed that the child had swallowed it. Three similar buttons were still attached to the coat. They were made of some smooth plastic material 5/8 in. in diameter and about 1/8 in. thick. I advised the mother to watch and examine the child's stools carefully for the next few days. By Dec. 3 the button had not been found, and so I sent the child for x-ray examination, instructing the mother to take the coat as the

radiologist would wish to test the opacity of the buttons. When, with this object in view, the coat was shown to the radiographer, no interest was aroused. The report to the mother by the doctor who examined the radiograph was that the child had not swallowed the button, but he gave instructions that if the child had any vomiting, diarrhoea, or signs of pain he should be taken back immediately. I received no report and decided on a "wait-and-see" attitude. Late on the night of Dec. 8 I was called to see the child, who had waked up crying and vomiting some hours after being put to bed. On examination no abnormal signs were found, and next morning the child was quite fit again. I heard no more of him until Dec. 31, when the mother told me that during the morning when she removed the child's soiled napkin she found the missing button in his stool, the holes in the button being well filled with faeces. It is interesting to note that the button took 32 days to traverse the intestinal tract, that apart from the occasion mentioned there were no abnormal signs, and that owing to the composition of the button the x-ray examination and report were valueless.

#### Dermatitis after Local Sulphonamides

Dr. J. SEGOBIN writes from the island of Rodriguez: The memorandum on dermatitis after local sulphanilamide treatment (April 3, 1943, p. 144) by Flight Lieut. Ian MacGregor is interesting. May I add my observation to it. A girl of 16 sustained a fall and her foot was bruised in the inner part of her left ankle by the kerb of a cemented footpath. After a few days the bruised tissue sloughed off, leaving a tropical ulcer of about 1½ in. diameter. In spite of various local treatments for six months there was no improvement, and I then decided to apply powdered sulphapyridine. The wound did well, but after two weeks' application of 1 tablet of 1/2 g. daily, the region below got irritated and took the form of a large weeping eczema, which was easily amenable to lotio plumbi and lin. calaminae. Fortunately the incident happened at the terminal stage of the ulcer, and the suspension of sulphapyridine did not affect its healing.

#### Herpes and Varicella

Dr. TH. JAMES writes from Induna, Southern Rhodesia: To comment on Dr. R. J. Gourlay's letter (Dec. 4, 1943, p. 736) about his case of chicken-pox following contact with shingles, surely it can be said to be quite an established fact that these two conditions are closely but yet inexplicably associated, and in circumscribed communities like those on air stations and in camps it is always a wise measure when a case of shingles occurs to look among the contacts for cases of early chicken-pox. If the cumulative evidence of numbers is required I can add two more. One of these cases showed the association very clearly. An airman developed some vesicles on his left chest and did not report sick but had a friend who applied a dressing of sorts, daily for several days, after which time, however, he did report sick with a typical shingles eruption. His friend who had done the dressings reported sick with chicken-pox about ten days later.

#### Non-Combatant Officers

Wing-Comdr. H. M. STANLEY TURNER writes: The current number of the *Journal of the Royal United Services Institution* contains an article on "The Dress of the British Army," by Major R. J. H. de Brett of the West Yorks Regiment, containing some interesting observations on the status of non-combatant officers—a class to which medical officers of all three Services belong. He says: "At present in the British Army, if an officer is to be given status in order that he may give orders and command respect, he has to be given the King's Commission, though he may not possess the technical qualifications which every holder of that Commission should possess." He continued: "A distinction between combatant and non-combatant officers is long overdue. Non-combatant officers should be given similar status to war correspondents and wear a uniform which clearly shows that they do not hold the King's Commission." Obviously if an individual does not hold the King's Commission he is not an officer, either combatant or non-combatant. What exactly the "technical qualifications" are which every holder of a Commission should possess the author unfortunately does not specify; nor does he enlighten us as to why medical officers should be given the status of war correspondents, even though they may be given the King's Commission to "command respect" if they have to "give orders," for they certainly fall within his definition of non-combatants.

#### Disclaimer

Squad. Ldr. G. WILLOUGHBY CASHELL, R.A.F., writes: The publicity in the lay press given to a recent communication of mine in the *British Medical Journal* was without my knowledge or consent.

#### Correction

In the *Journal* of April 15 (p. 546) under the heading "*Trichomonas vaginalis*," the first word of the second paragraph of the answer to the question should read "Liston," and not "Lison." The reference is *Brit. J. vener. Dis.*, 1940, 16, 34.

## THE CONTROL OF DUST-BORNE STREPTOCOCCAL INFECTION IN MEASLES WARDS

BY

JOYCE WRIGHT, D.M. ROBERT CRUICKSHANK, M.D., M.R.C.P., D.P.H.

AND

WILLIAM GUNN, M.B., Ch.B., F.R.C.P., D.P.H.

(From the L.C.C. North-Western Hospital and Group Laboratory, Hampstead)

Hospital trials on the control of dust-borne infection by oiling blankets, ward linen, garments, and floors were carried out in scarlet fever and measles wards in this hospital during the spring of 1942 and of 1943. The work in a scarlet fever ward, while on the whole encouraging, awaits the result of further tests before being recorded. The results of a controlled test in two measles wards are now reported.

The haemolytic streptococcus has for many years been recognized as a predominant secondary invader in measles and as an important cause of its serious complications—e.g., otitis media, mastoiditis, and bronchopneumonia. The virus-damaged mucous membrane of the respiratory tract, the catarrhal nature of the primary infection, and the overcrowding of patients in hospital at epidemic times all combine to favour the acquisition and spread of streptococci. The incidence of otitis media among measles patients may be as high as 20% (Allison and Brown, 1936); and of the patients so affected as many as 30% may develop mastoiditis. The frequency and severity of its complications made measles an important infection among the camp diseases of the United States Army during 1917 and 1918 (Michie and Lull, 1928). Its most serious consequences were pneumonia, empyema, and otitis media, which in the majority of cases were due to haemolytic streptococci. Cole and MacCallum (1918) found that a haemolytic streptococcal throat-carrier rate of 11.4% among measles patients on admission to hospital had risen to 38.6% after 3 to 5 days in the wards and to 56.8% after 8 to 16 days. They concluded that the chance of developing post-measles streptococcal infection was increased by residence in hospital, and that the high incidence of pneumonia, and the resulting high mortality, were due in part to infection occurring within the hospital. The sequence of events has become clearer since Griffith (1934) extended his method for the serological typing of *Str. pyogenes*. Allison and Brown (1936) were thus enabled to make a survey in a measles ward. They took nose and throat swabs from 43 patients once weekly from admission to discharge, and appropriate swabs on the occurrence of any complication. By typing the strains of *Str. pyogenes* which they had isolated they showed that cross-infection with these organisms occurred in 22—i.e., 51.2%—of the 43 patients; and that of the patients thus cross-infected 13 developed complications as a result (7 otitis media; 1 scarlet fever with otitis media; 1 rhinitis; 4 rise of temperature only). In other words, 19% of the measles patients developed otitis media consequent upon cross-infection with streptococci.

The work of Brown and Allison (1937) and of Cruickshank and Godber (1939) suggested that dust may be an important vehicle of haemolytic streptococci among patients with upper respiratory tract infections. These investigations revealed an

increase in the number of streptococci in the ward air during bed-making and sweeping activities. Later, Thomas and van den Ende (1941) observed that in a ward containing tonsillitis cases both floor-sweepings and bed-clothes were heavily contaminated with haemolytic streptococci. Van den Ende, Thomas, and colleagues (van den Ende, Lush, and Edward, 1940; Thomas, 1941; Thomas and van den Ende, 1941; van den Ende, Edward, and Lush, 1941; van den Ende and Spooner, 1941; van den Ende and Thomas, 1941) investigated possible measures for the control of dust-borne infection in wards. The dust-laying effect of spindle oil when applied to floors was tested in field trials by Thomas, who found that the method produced a prolonged and marked reduction in the number of bacteria in the air during sweeping. Since, however, the main source of the bacteria-carrying particles lay in the bed-clothes, van den Ende and co-workers devised methods for the treatment of woollen and cotton materials with technical white oil, which reduced by 99% the number of micro-organisms liberated during bed-making. The method of oiling ward articles by the use of oil-in-water emulsions (van den Ende and Thomas, 1941) during the laundering process has been modified and made more practicable for large-scale application by Harwood, Powney, and Edwards (1944) of the British Launderers' Research Association. These workers describe their technique in an article at page 615 of this issue.

### Scope of the Investigation

The purpose of this work was to find out if, in a measles ward, the oil treatment of floors, bed-clothes, linen, etc., would reduce: (1) the number of haemolytic streptococci in the air during sweeping and bed-making, (2) the incidence of cross-infection by haemolytic streptococci, (3) the incidence of clinical complications due to such cross-infection.

The work was undertaken for 12 consecutive weeks during March, April, and May, 1943, in two measles wards, identical in size, design, and aspect. In one—the Control Ward—no measures were taken against dust-borne infection. In the other—the Test Ward—the following measures were taken: during the first three weeks the floor was treated with spindle oil; during the subsequent nine weeks the floor was re-oiled every four weeks, and all blankets, counterpanes, sheets, pillow-slips, patients' garments, towels, gowns, white coats, curtains, etc., were treated with technical white oil during laundering. The blankets of each patient were disinfected after his discharge or transfer from the ward, and were washed and re-oiled every four weeks. The articles were oiled at the Laboratories of the British Launderers' Research Association. The bacterial content of the air, and the cross-infection and complication rate due to haemolytic streptococci, were studied in both wards throughout the investigation.

### Ward Arrangements

1. The normal bed complement was 18 for each ward, and the normal spacing was 12 feet between bed-centres. During ten weeks of the investigation two extra beds, and during two weeks four extra beds, were put up in each ward, and the bed-spacing was correspondingly reduced.

2. So far as was practicable, patients were admitted alternately to the two wards.

3. Sulphonamides were given prophylactically to all patients unless there was any contraindication. During the first three weeks of the work a number of different drugs were used, in varying doses and for varying times. An intensive scheme was then introduced, and alternate patients admitted to each ward received sulphanilamide or sulphathiazole. The dosage, according to age, was 1 to 2 g. on admission, 3 to 7.5 g. daily for 3 days, followed by 1.25 to 3.75 g. daily till the day before discharge.

4. On admission prophylactic mixed scarlet fever and diphtheria antitoxin was injected into 54 (70.1%) of the 77 patients in the *Control Ward*, and into 56 (55.4%) of the 101 patients in the *Test Ward*.

5. Toys from both wards were periodically disinfected by heat. (During the later part of the work each patient in the *Test Ward* was allotted one toy, which was disinfected when he left. Had this plan of toy control been noticed earlier a similar method would have been adopted in the *Control Ward* also.)

6. Mattress, pillows, and blankets of each patient were disinfected in the hospital steam disinfector (5-lb. pressure for 30 minutes) on his discharge or transfer from the wards.

7. Patients with suppurative otitis media, if retained in the wards, were barrier-nursed. Feeding and sanitary utensils used by these patients were disinfected after use.

### Routine Procedure

**Air Sampling.**—The bacterial content of the ward air was investigated by means of a slit sampler (Bourdillon, Lidwell, and Thomas, 1941). At intervals of 7 to 14 days air samples were taken in each ward during the early morning bed-making and sweeping times. The machine, on a trolley, was moved from one bed to the next as each in turn was made. During sweeping the machine remained at a central position in the ward. The height of the slit, through which air was drawn at the rate of one cubic foot a minute, was four feet from the floor. For measuring the total bacterial content of the ward air blood-agar plates were exposed in the slit sampler for one to three minutes, and were incubated aerobically for 24 hours at 37° C. The number of bacterial colonies (and, if not overgrown, the number of haemolytic streptococcus colonies) was counted on each plate. On crowded plates only an approximate count could be made. The total volume of air sampled for total bacteria was 8 cu. ft. on each occasion during bed-making or sweeping. For measuring the haemolytic streptococcus content of the air gentian-violet blood-agar plates were exposed in the slit sampler for 5 to 15 minutes. The number of haemolytic streptococcus colonies on each plate was counted after 24 hours' incubation at 37° C. aerobically, and representative colonial forms were transferred to blood broth for subsequent serological typing by the slide-agglutination method of Griffith. The total volume of air sampled on each occasion for haemolytic streptococci was 50 cu. ft. during bed-making and 30 cu. ft. during sweeping.

**Cross-infection Incidence.**—At the start of the investigation nose and throat swabs were taken from all patients in both wards. Subsequently, swabs were obtained from the nose and throat and from any suppurative lesion—e.g., ear discharge, impetigo—of every new patient, immediately before admission to the wards and then once weekly. Nose and throat swabs were taken from each member of the ward staff once monthly, and also on the development of any upper respiratory tract infection. Swabs were plated on gentian-violet blood-agar plates and incubated aerobically for 18 hours at 37° C. Representative colonial forms of haemolytic streptococci were tested for their serological type. Cross-infection was judged to have occurred if a patient, free from haemolytic streptococci on admission, acquired these organisms in the nose or throat; or if a patient who carried haemolytic streptococci on admission acquired haemolytic streptococci of different type in the nose or throat. In assessing the cross-infection rate the Type 6 streptococcus was adopted as the "indicator organism," since more than 90% of the cross-infections in both wards were due to this type. For completeness, however, all cross-infections with other serological types are recorded.

**Complication Rate.**—A daily round of all the patients in both wards was made and any complication or rise of temperature noted. Appropriate swabs were taken and plated on blood agar, and/or gentian-violet blood agar, and/or tellurite medium, according to the nature of the complication. Ear and mastoid swabs were investigated for the presence of haemolytic streptococci, pneumococci,

staphylococci, and diphtheria bacilli. Any haemolytic streptococci isolated from patients with complications were tested for serological type.

### Results of Investigation: Preliminary Period

During a preliminary period of three weeks the routine investigations were carried out in both wards. The only difference in dust control between the two wards during this time was that the floor of the *Control Ward* was unoled, while that of the *Test Ward* was oiled.

**Air Sampling.**—Air samples were taken once weekly in each ward during the bed-making round. In the *Control Ward* the samples yielded respectively 103, 265, and 349 haemolytic streptococcus colonies per 50 cu. ft. of air. The high count of 349 on one occasion was largely due to one sample of 10 cu. ft. which yielded 177 colonies. All of 15 colonies tested serologically were Type 6. In the *Test Ward* the samples yielded respectively 149, 117, and 98 haemolytic streptococcus colonies per 50 cu. ft. of air. Thirteen of 14 colonies tested serologically were Type 6.

**Cross-infection Rate.**—At the start of the investigation 8 (36.4%) of the 22 patients in the *Control Ward* had Type streptococci in the nose and/or throat; in addition one had Type 2 and one had Type 27 streptococci. During the preliminary period 16 (53.3%) of the 30 patients at risk (i.e. Type-6-negative either at the start of the period or on admission) acquired Type 6 streptococci in the nose and/or throat. In addition two other patients acquired Type 2 and Group C streptococci respectively. Seven (38.9%) of the 18 patients already in the *Test Ward* had Type 6 streptococci in the nose and/or throat; in addition one patient had Type "Impetigo 19," and one had Type 12 streptococci. During the preliminary period 18 (58.1%) of the 31 patients at risk acquired Type 6 streptococci in the nose and/or throat. In addition two patients acquired "type not determined" and Type 14 streptococci respectively.

**Complication Rate.**—During the preliminary period 7 patients out of 38 at risk in each ward developed middle-ear suppuration due to cross-infection with Type 6 streptococci. The ear-complication rate due to cross-infection was therefore 18.4% in each ward.

These results disclosed that conditions in the two wards were remarkably similar during the preliminary period. In both between 36 and 39% of the patients were harbouring the Type 6 streptococcus at the start of the work; in both the cross-infection rate with this type lay between 53 and 59%; in both the middle-ear complication rate, due to Type 6 streptococcus, was 18.4%; and in both numerous Type 6 streptococci were present in the ward air during bed-making.

### Test Period

During the subsequent nine weeks the same investigations were continued in both wards. In the *Control Ward* no steps were taken during this period against dust-borne infection, whereas in the *Test Ward* the full measures of dust control—i.e., oiled floors, oiled bed-clothes, oiled garments, etc.—were maintained throughout. The change-over to oiled bed-clothes and other articles was accomplished in one day, and the floor was re-oiled on the same day.

**Air Sampling.**—Table I shows the results of air sampling at bed-making times in the two wards during the test period.

TABLE I.—Counts of Total Bacteria and of Haemolytic Streptococci in Air during Bed-making in Control and Test Wards

Ward	Date	Total Bacterial Colonies (approx.) developing per 8 cu. ft. of Air	Haemolytic Streptococci Colonies developing per 50 cu. ft. of Air
Control	3/4/43	14,610	147
	15/4/43	15,540	131
	1/5/43	12,580	97
	13/5/43	5,240	218
	20/5/43	7,580	39
	26/5/43	1,120	7
Test	2/4/43	1,780	10
	9/4/43	1,013	2
	17/4/43	685	2
	30/4/43	1,845	0
	14/5/43	445	0
	22/5/43	390	0

Table II shows the results of air sampling at sweeping times in the two wards during the test period. Forty-eight colonies of haemolytic streptococci isolated from the air in the *Control Ward* were tested serologically; of these, 37 were Type 6. Eight colonies from the air of the *Test Ward* were typed, and all were Type 6. The reduction in the bacterial counts of the

TABLE II.—Counts of Total Bacteria and of Haemolytic Streptococci During Sweeping in Control and Test Wards

Ward	Date	Total Bacterial Colonies (approx.) developing per 30 cu. ft. of Air	Haemolytic Streptococcal Colonies developing per 30 cu. ft. of Air
Control	3/4/43	4,093	37
	13/4/43	15,260	34
	15/5/43	2,100	52
	13/5/43	1,500	9
	20/5/43	846	10
Test	2/4/43	226	1
	17/4/43	250	0
	30/4/43	810	0
	17/5/43	355	0
	22/5/43	315	0

air in the *Control Ward* towards the end of the experiment may have been due to two factors: (a) the improved weather and longer days, which allowed better natural ventilation; and (b) the reduction in the number of patients in the *Control Ward*, which during the last two weeks had a varying daily complement of 7 to 13, compared with 12 to 17 in the *Test Ward*.

**Cross-infection Rate.**—During the test period 30 (73.3%) of the 41 patients at risk in the *Control Ward* acquired Type 6 streptococci in the nose and/or throat. The infections were distributed regularly throughout the period. Cross-infection with other streptococcal types did not occur. During the test period 11 (18.6%) of the 59 patients at risk in the *Test Ward* acquired Type 6 streptococci in the nose and/or throat. In addition three other patients acquired Group A "type not determined," Group C, and Type "B 3264" streptococci respectively. The ward was never free from a source of the Type 6 streptococcus, the number of patients harbouring this organism at any one time varying from a maximum of nine to a minimum of one. The time during which there was only one source present was eight days. The Type 6 cross-infections were distributed as follows: 2 in the last week of March, 2 in April, and 6 in May.

**Complication Rate.**—During the test period 7 (14.3%) of the 49 patients at risk in the *Control Ward* developed middle-ear suppuration due to Type 6 streptococcus. During the same period 2 (2.8%) of the 72 patients at risk in the *Test Ward* developed middle-ear suppuration due to Type 6 streptococcus. The other cross-infecting strains caused no complications.

Chart showing cross-infection rate (cross-hatching) and middle-ear infection rate (black columns) due to Type 6 streptococci in (a) *Test Ward* with oiled bed-clothes, garments, and floor; (b) in *Control Ward* with no anti-dust measures.

#### Sources and Spread of Haemolytic Streptococci

**Patients.**—The Type 6 "indicator" streptococcus was well established at the beginning of the investigation. It was not possible to trace its origin, but its presence in both wards may have been due to the transfer of patients from one ward to the other a few weeks before this investigation began. Haemolytic streptococci of various other types were brought into both wards in the noses and throats of newly admitted patients. The carrier rate among new patients to the *Control*

*Ward* was 18.2%, and to the *Test Ward* 12.2%. The type distribution, taking the two wards together, was: Group A, "type not determined," 4; Type 27, 4; Type 11, 2; Types 4/24, 6, 12, 13, 22, 28, "Impetigo 19," one each; Groups C and G, one each. One patient was admitted to the *Control Ward* and two patients to the *Test Ward* with streptococcal otorrhoea. Two of these (one with Type 1 and one with Type 6) were removed from the wards after a few days. The third (Type 22) was nursed in the *Test Ward*. There was no evidence that strains of streptococci in the upper respiratory tracts of new patients spread to other patients in the wards during the period of investigation.

Convalescent patients may become cross-infected after they are allowed up. Thus 5 of the 11 cross-infections in the *Test Ward* were first discovered in the swabs taken on the morning of the patients' discharge from hospital. Apparently they acquired the infection during convalescence by "visiting" infected patients in the ward.

**Ward Staff.**—Haemolytic streptococci were isolated from five members of the staff in the *Control Ward* at the routine swabbing. The type distribution was: Group A, "type not determined," 3; Type 6, 2. The two nurses with Type 6 streptococci developed sore throats. Haemolytic streptococci were isolated from four members of the *Test Ward* staff, with the following distribution: Type 6, 2; Types 12 and 25, one each. From time to time fingers of the ward staffs were swabbed, and it was not uncommon to find haemolytic streptococci upon them.

**Ward Articles.** Toys, etc.—Haemolytic streptococci, often in large numbers, were grown from toys, magazines, baths, tablecloths, bibs, spoons, tables, floors, etc., in both wards.

**Nasal Toilet.**—This was performed with cotton-wool rolled at the bedside on to wooden applicators. Petroleum jelly from a common pot was spread on the lips and face with the fingers. Numerous haemolytic streptococci were found in the petroleum jelly, and, as already mentioned, these organisms were also found on the nurses' fingers.

#### Chemoprophylaxis and Sulphonamide Resistance

Streptococcal cross-infections and their resulting complications occurred in spite of the fact that prophylactic sulphonamides were given to the majority of the patients in both wards. Of the Type 6 cross-infections, 37 of the 46 (80.4%) in the *Control Ward* and 20 of the 29 (69%) in the *Test Ward* were contracted while the patients concerned were receiving these drugs. A possible explanation of the ineffectiveness of chemoprophylaxis in preventing the spread of Type 6 streptococci lay in the fact that these strains in both wards were, as shown by *in vitro* tests, sulphonamide-resistant.

#### Complications resulting from Cross-infection

All cases of otorrhoea and of mastoiditis which developed after admission in both wards were the result of Type 6

TABLE III.—Nature and Distribution of Type 6 Streptococcus Complications in Control and Test Wards

Ward	Nature of Complication	No. of Cases	
		Preliminary Period	Test Period
Control	S.O.M., unilateral or bilateral	6	4
	R.S.O.M., B. mastoidectomy and gastro-enteritis	—	1
	L.S.O.M. and L. mastoidectomy	—	1
	L. mastoidectomy and extradural abscess of middle fossa	1	—
	B. mastoidectomy	—	1
	Skin sepsis	3	1
	Conjunctivitis	—	—
	Sore throat	—	1
	Purulent rhinitis	1	1
	Rise of temperature only	—	—
Test	S.O.M., unilateral or bilateral	2	2
	R.S.O.M. and R. mastoidectomy	—	—
	R.S.O.M. and orbital cellulitis	1	—
	Ulcerated lip	—	1
	Scarlet fever	—	1
	Rise of temperature only	2	2

R. = Right. L. = Left. B. = Bilateral. S.O.M. = Suppurative otitis media.

streptococcus cross-infection. Table III shows that other complications due to cross-infection by this type also occurred. It lists these together with the middle-ear complications. In

the *Test Ward* five children developed dermatitis or erythema of the skin. The reactions, which were mild and quickly subsided, may have been caused by the oil-treated undergarments, since evidence of skin irritation was also observed among scarlet fever patients after wearing similarly oiled garments. This problem is being further investigated.

### Discussion

The results demonstrated that most of the serious complications in the measles wards were due to haemolytic streptococcal cross-infection. At the start of the work there was a heavy load of streptococcal infection in both wards. Toys, books, baths, and other ward articles yielded these organisms in abundance; and more than a third of the patients harboured Type 6 streptococci in the upper respiratory tract. We found also in the preliminary period that this type spread to more than half of the new patients, and caused one in every five to develop suppuration of the middle ear.

For a number of reasons we chose to control dust-borne infection rather than that carried by other means. Haemolytic streptococci multiply, almost as if in artificial culture, on the susceptible mucous membranes of measles patients. The catarrhal character of the disease favours gross contamination of bed-clothes and garments, from which on movement infected dust particles are released into the air. The streptococci are then free to infect fresh patients or to reinfect those already affected. They also contaminate the ward dust, and rise into the air again during sweeping and dusting. Air samples showed that during bed-making the air was heavily charged with haemolytic streptococci and, to a less extent, during sweeping. In the busy measles wards there was a constant stir and therefore a steady contamination of the air. Contact and droplet infection could not be disregarded, but they appeared to be occasional risks only, compared with the day-and-night inhalation of infected dust particles.

A further reason for our attempt to control dust-borne infection was the fact that there were means available of reducing and, possibly, of eliminating it. The first method which we tried was the treatment of the *Test Ward* floor with spindle oil, but we quickly discovered that this by itself was not enough. During a three-weeks trial of this method the air during bed-making contained 100 to 150 haemolytic streptococci per 50 cu. ft., the cross-infection rate (58.3%) was rather higher in the *Test* than in the *Control Ward*, and the ear-complication rate of 18.4% was the same in both wards. These findings are not surprising if the paths of dust-borne infection are considered: upper respiratory tract  $\rightarrow$  droplets and discharges  $\rightarrow$  bed-clothes and garments  $\rightarrow$  ward air during bed-making  $\rightarrow$  ward dust  $\rightarrow$  ward air during sweeping. Thus the application of dust-laying oil to floors breaks only the last link in the chain; it does not influence the first and main reservoir of infected dust particles—the bed-clothes and garments of infected patients. Our second method of attack, therefore, was directed at this earlier link in the chain. The marked reduction in the number of aerial streptococci and in cross-infection and complication rates which followed the oiling of all blankets, ward-linen, and garments has been recorded above. It was, of course, possible that a spontaneous waning of the streptococcal cross-infection in the *Test Ward* had coincided with the introduction of the full anti-dust measures, but it seemed unlikely, for a reservoir of the cross-infecting Type 6 streptococcus never failed in the *Test Ward*, and new patients were admitted at the rate of about one a day. Their susceptibility was shown by the fact that a high cross-infection rate with the same streptococcus prevailed in the *Control Ward* among new patients, drawn from the same population during the same period.

Although the cross-infection rate was greatly reduced in the *Test Ward* after the introduction of oiled bed-clothes and garments, the residual incidence of 18.6% was still too high to allow of complacency. For the further prevention of secondary streptococcal infection in a measles ward measures may be required against mediate infection by fingers, toys, petroleum jelly, etc., and against direct droplet spread by staff carriers or between new and convalescent patients. On the other hand, it seems reasonable to assume that a heavy load of streptococcal infection would have been averted had anti-

dust measures been introduced at the opening of the ward so that these precautions might by themselves have sufficed to prevent clinical complications.

Thus our results suggest that cross-infection in measles wards is mainly due to dust-borne streptococci, which can be controlled by the oiling of floors, bed-clothes, and garments, but not by the oiling of floors alone. However, experience of these new methods of dust control is as yet not sufficient to justify any final judgment on their efficacy, and they should not be pressed into routine service until their advantages and limitations are more fully explored. There seems good reason to believe that they would prove useful in controlling secondary bacterial infection among influenza patients who may have to be nursed in large open wards. Anti-dust measures might also be tried in institutions—e.g., residential schools and training establishments—where respiratory infections are apt to spread.

### Summary

An investigation into the control of dust-borne haemolytic streptococci was carried out in two measles wards of identical design in the spring of 1943. In the *Test Ward*, during a three-weeks preliminary period, the floor alone was oiled. During a nine-weeks period bed-clothes, patients' garments, and all woollen and cotton articles in ward use were treated regularly with emulsions of technical white oil, and the floor was re-oiled at intervals. In the *Control Ward* no anti-dust measures were taken. In both wards the air was sampled for total bacteria and for haemolytic streptococci during bed-making and sweeping, and the streptococcal cross-infection and complication rates were determined and analysed. In assessing the cross-infection rate Type 6 streptococcus was adopted as the "indicator organism," since in the wards it accounted for 90% of the cross-infections and for all middle-ear complications occurring after admission.

In the *Test Ward*, while the floor alone was oiled the Type 6 cross-infection rate was 58.1%, compared with a rate of 53.3% in the *Control Ward*. In each ward the middle-ear complication rate due to Type 6 was 18.4%. Haemolytic streptococci were numerous in the air of both wards during bed-making, the predominant type being Type 6. Thus oiling of floors alone was not sufficient to control the spread of dust-borne haemolytic streptococci in measles wards.

In the *Test Ward*, while the full anti-dust measures of oiled bed-clothes, garments, etc., and oiled floor were in force: (a) the mean haemolytic streptococcus count in the air during bed-making was reduced by 97.5%; (b) the mean bacterial count in the air during bed-making was 91% less, and the mean haemolytic streptococcus count 98% less, than in the *Control Ward*; (c) the mean bacterial count in the air during sweeping was 92% less, and the mean haemolytic streptococcus count 99% less, than in the *Control Ward*; (d) the Type 6 cross-infection rate was 18.6%, while in the *Control Ward* it rose to 73.3%; (e) the middle-ear complication rate due to Type 6 was 2.8%, compared with 14.3% in the *Control Ward*. Thus the oiling of all bed-clothes and ward-linen, in addition to the oiling of floors, effectively controlled dust-borne streptococcal infection in measles wards. Cross-infection from direct contact or mediate means was not prevented by anti-dust measures.

A high streptococcal infection rate occurred in spite of intensive sulphonamide prophylaxis. The cross-infecting Type 6 strain was found by *in vitro* tests to be sulphonamide-resistant.

We wish to thank Drs. M. van den Ende, C. H. Andrewes, and R. B. Bourdillon for their helpful advice and for the loan of apparatus; Drs. M. B. Alexander and Y. Eiser, the medical officer of the wards; Miss Kelly, the matron, Deputy-Sisters Daltie Knaggs, and Barnett, and the nursing staff of the North-West Hospital for their co-operation and assistance; Drs. S. D. Elliott and D. Colebrook for streptococcal typing sera; Dr. L. Colebrook for help with the sulphonamide-resistance tests; and the Medical Research Council for a personal grant to one of us (J. W.).

## A NEW TECHNIQUE FOR THE APPLICATION OF DUST-LAYING OILS TO HOSPITAL BED-CLOTHES

BY

F. COURTNEY HARWOOD, B.Sc.

J. POWNEY, Ph.D., B.Sc.

AND

C. W. EDWARDS, B.Sc.

(From the British Launderers' Research Association Laboratories,  
Hill View Gardens, Hendon; N.W.4)

The treatment of bed-clothes with dust-laying oils for the purpose of reducing dust-borne infection in hospital wards has recently been investigated in some detail (van den Ende, Edward, and Lush, 1941; van den Ende and Thomas, 1941; Thomas and van den Ende, 1941). It was found that the application of from 3 to 7% of liquid paraffin or of technical white oil to bed-clothes caused a very large reduction of dust-borne bacteria in the air of hospital wards. Two distinct methods of applying the oil to bed-clothes were studied by these authors: (a) impregnation with oil dissolved in a volatile organic solvent; (b) impregnation with concentrated oil-in-water emulsions.

Neither of these processes permits accurate control of quantities, while, from an economic point of view, both methods entail a recovery process for the unused oil, and would present considerable difficulty in large-scale operation in a hospital laundry. Early in 1942 Dr. van den Ende, of the National Institute for Medical Research, invited the co-operation of the British Launderers' Research Association with regard to this difficulty, and an investigation was carried out in these laboratories in which the use of dilute aqueous emulsions for oiling was considered in detail. As a result of this work an efficient and economic process has been evolved and applied on a large scale. It is the purpose of this paper to present the theoretical considerations and practical details of the process.

### Experimental

A process in which aqueous emulsions of oil are used has obvious advantages over a process in which it is necessary to employ an inflammable solvent. Palmer and Blow (1938) have advocated the use of cation-active agents for the deposition of mineral oil on to wool during certain stages of manufacture, but it is not possible to ascertain from their published data whether complete exhaustion of the emulsion was obtained. During a previous investigation carried out in these laboratories on the influence of cation-active emulsifiers such as cetyl pyridinium bromide upon the electric charge of oil drops (Powney and Wood, 1940), it was found that high positive charges could be established on the drops at extremely low concentrations; furthermore, it was found that at these very low concentrations the electric charge on many non-oily surfaces (usually negative) underwent a relatively insignificant change. It was thought, therefore, that this effect might possibly be utilized to obtain the complete discharge of a dilute oil emulsion on to fabrics.

### Oiling of Wool Fabrics

Preliminary small-scale tests on wool showed that it was possible completely and rapidly to exhaust a dilute oil-in-water emulsion stabilized with a certain concentration of cetyl pyridinium bromide. The amount of oil which can be applied to wool fabric in this manner may be adjusted to almost any requirement. It is necessary for an effective discharge that the liquor shall be maintained in a slightly alkaline state—e.g., at pH 8—as under this condition the cation-active agent is rapidly adsorbed by the wool. It should be emphasized that, by this method, only that amount of oil which is actually required on the fabric is added to the machine, the final waste liquor being virtually clear water. For convenience, concentrated 20% oil emulsions were prepared, and were diluted according to the amount of oil required on the fabric.

### Example

100 g. wool fabric.  
1,000 c.cm. soft water at 100° F.  
25 c.cm. positively charged stock oil emulsion stabilized by "fixanol C."

The fabric was squeezed by hand in this liquor for approximately 10 minutes, after which time all the oil had apparently been taken up by the wool, the resulting liquor being quite clear. The fabric was then hydro-extracted and air-dried. If the deposition of oil was complete there would have been 5% of oil (based on the dry weight of the fabric) present on the wool. The oil content of the sample was ascertained by means of extraction with petroleum ether:

Oil on fabric (calculated) .. ..	5%
" " " (found) .. ..	4.8%

Practically all the oil had therefore been deposited on the fabric.

### Oiling of Cotton Fabrics

By using the above method with cotton fabrics some difficulty was experienced in obtaining complete deposition of oil from the positively charged emulsion. This was overcome by using half the requisite amount of oil as a positively charged emulsion, and subsequently adding the remainder of the oil as a negatively charged emulsion.

### Example

100 g. cotton fabric.  
1,000 c.cm. soft water at 100° F.  
17.5 c.cm. positively charged stock oil emulsion stabilized by "fixanol C."

The procedure in this instance was to squeeze the cotton fabric for 2 to 3 minutes in this liquor and then to add 17.5 c.cm. of a negatively charged stock oil emulsion stabilized by "teepol."† On further squeezing up to 10 minutes deposition was again apparently complete. The fabric was hydro-extracted and dried as before. In this instance the oil content of the dry fabric should have been 7% if all the oil had been deposited:

Oil on fabric (calculated) .. ..	7%
" " " (found) .. ..	6.9%

### Large-scale Operation

At this stage the results of the preliminary laboratory experiments appeared to be satisfactory enough to warrant the operation of the process on a large scale. Arrangements were therefore made for a series of tests to be carried out in scarlet fever and measles wards at the L.C.C. North-Western Hospital in order to ascertain how the incidence of cross-infection was affected by the use of oiled bed-clothes and ward hangings. The British Launderers' Research Association undertook to oil all the necessary articles at its Research Station after they had been washed and rinsed at the hospital laundry. During a period of four months some four tons of articles, including sheets, blankets, pillow-cases, counterpanes, bed-jackets, nightgowns, bibs, restrainers, nurses' gowns, black-out curtains, screens, etc., were treated in normal laundry washing machines.

Oiling takes place after the goods have been correctly washed and rinsed, and it is emphasized that level oiling cannot be obtained if fabrics are washed in hard water, whereby deposition of calcium and magnesium soaps occurs. The last rinsing water is adjusted to a predetermined volume by observing the height of the water in the dip gauge on a standard rotary washing machine, typical processes for the oiling of woollen and cotton articles being given below.

Two aqueous emulsions of technical white oil were prepared; the positively charged emulsion employed "fixanol" as the stabilizing agent at an approximate concentration of 2%, while the negatively charged emulsion employed "teepol" as the stabilizing agent at an approximate concentration of 3%. The

\* "Fixanol C" is a cation-active agent of the cetyl pyridinium bromide type manufactured by Imperial Chemical Industries Ltd. The paste contains approximately 50% of active material.

† "Teepol" is an anion-active agent based on the sodium salts of sulphated secondary alcohols of average chain length 13.2 carbon atoms. The product contains approximately 22% of active material, and is manufactured by Technical Products Ltd.

quantity of oil used in each case was equivalent to 20% of the mixture by volume, and it was finely dispersed by employing an emulsifier which operated on the jet principle. These strong emulsions tended to cream on standing, and it was essential to stir thoroughly before removing the requisite quantities for addition to the washing machine. There would appear to be no reason, however, why more concentrated emulsions containing up to 40 to 50% of oil should not be prepared; and the tendency to cream might be considerably minimized by using a more efficient homogenizer.

#### Process A—for Oiling Woollen Goods

1. Size of rotary washing machine, 34 in. by 54 in. Dry weight of load, 70 lb.
2. Adjust the quantity of softened water used in the last rinse so that, when the machine is running with the load in, the gauge glass registers a dip of 10 in.
3. Adjust temperature of water to 100° F.
4. Add stock "fixanol" emulsion (20% oil content)—1½ gallons.
5. Run machine for 10 minutes, interrupting the rotation periodically to minimize any tendency of the goods to shrink.
6. Stop machine and unload.
7. Hydro-extract and dry in the normal manner.

This process will give a level deposition of oil equivalent to 5% of the weight of the goods.

#### Process B—for Oiling Cotton Articles

1. Size of rotary washing machine, 34 in. by 54 in. Dry weight of load, 100 lb.
2. Raise temperature to 100–120° F.
3. Add stock "fixanol" emulsion (20% oil content)—1½ gallons.
4. Run machine for 2 to 3 minutes without interrupting the rotation.
5. Add stock "teepol" emulsion (20% oil content)—1½ gallons.
6. Run machine for a further 7 to 8 minutes without interrupting the rotation.
7. Stop machine and unload.

This process will give a level deposition of oil equivalent to 6% of the weight of the goods.

During the present hospital trial it was found that the majority of the "woollen" articles to be treated were in fact composed of a mixture of wool and cotton; in view of this it was necessary to use Process B for such articles, since it was found that if Process A, for pure woollens, was used there was an uneven distribution of oil between the wool and the cotton components. The use of Process A for articles of pure wool is optional, since they can also be effectively oiled by Process B. It must be stressed here that the successful operation of this type of oiling process depends largely upon its being preceded by an efficient laundry washing and rinsing procedure. This is particularly true if adequate rinsing of the load has not been carried out, or if there is an accumulation of lime soaps on the articles owing to the use of unsoftened water. Apart from these considerations there is no reason why the oiling should not be carried out by the normal laundry staff, and if the machines used are afterwards rinsed out with hot water no difficulty should be encountered with subsequent washes. After hydro-extraction the load can be finished by the normal methods. No appreciable amount of oil is lost during the calender-drying of cotton articles. There is a slight but unimportant decrease of oil content when blankets and other woollen articles are autoclaved at 5-lb. steam pressure. Thus wool test-pieces having an average oil content of 5.2% showed average oil content of 5.07% after treatment in an autoclave at 5-lb. steam pressure for one hour.

#### Accumulation of Oil

Over a period of successive oilings and washings it was found that there was a definite accumulation of oil in the case of woollen articles, which can only be given a low-temperature wash. Mineral oil such as technical white oil is well known to be extremely difficult to remove completely from textile fibres, and it is therefore not surprising that a progressive building up should occur. It is not desirable that the oil content should rise appreciably above about 5 to 7%, and the degree to which this accumulation may occur will depend largely upon the efficiency of the particular washing process. It is therefore not possible to give any general recommendation by which it can be prevented. A fairly steady degree of oiling can probably be maintained if in the initial

oiling treatment an increased amount of emulsion is used and in all subsequent treatments the amount of emulsion is reduced below that given in the process chart. If laboratory facilities are available the most satisfactory method of control is to incorporate a wool and a cotton test-piece in the respective types of load and to remove, after each oiling, a sample for Soxhlet extraction with petroleum ether. In this way any serious accumulation of oil can readily be detected and appropriate adjustments in the amounts of emulsions used can be made.

#### Discussion

During the present investigation it has been found possible, by the use of suitable emulsifiers, to oil hospital bed-clothes, etc., to any required degree by means of very dilute oil-in-water emulsions. The particular advantage of the present process over that previously described by van den Ende and Thomas is that complete exhaustion of the emulsion takes place, and there is therefore no necessity for applying any oil-recovery process to the used liquor. Both positively charged and negatively charged oil emulsions have been employed, either separately or in equivalent amounts. The cation-active emulsifier "fixanol C" and the anion-active emulsifier "teepol" have been used in the present investigation, but there is no reason why other commercial emulsifiers of similar types should not be used. The methods described are applicable on a large scale in any hospital laundry that observes a correct washing technique.

We tender our thanks to the Council of the British Launderers' Research Association for permission to publish this paper.

## OILED FLOORS TO CONTROL RESPIRATORY INFECTION

### AN ARMY EXPERIMENT

BY

P. H. R. ANDERSON, M.B., Ch.B., B.Sc.  
*Lieut.-Col., R.A.M.C.*

J. A. BUCHANAN, M.B., Ch.B.  
*Capt., R.A.M.C.*

AND

J. J. MacPARTLAND, M.B., B.Ch.  
*Capt., R.A.M.C.*

The use of spindle oil to lay the dust on floors and so diminish the number of bacteria in the air was described by van den Ende, Lush, and Edward (1940), and by Thomas (1941). The importance of such air-borne organisms in the spread of respiratory and cross-infections has been emphasized by many writers (Cruickshank, 1935, 1941; White, 1936; Allison and Brown, 1937; M.R.C. War Memo. No. 6, 1941). It therefore appeared of some importance to see if oiling of floors could be used to cut down the spread of air-borne infections among soldiers in barracks. An experiment to test this possibility was suggested and arranged by Col. W. W. S. Sharpe, and was carried out between Dec., 1942, and March, 1943. It gave encouraging results, and, as the general conclusions seem to have aroused some interest (*British Medical Journal* leader 1943), it may be of value to give a short account of the details

#### Conditions of the Experiment

The experiment involved the men in two Army units, A and B, each of which was a large training centre occupying one complete barracks. Oiling of floors was carried out in unit A, while in unit B, which served as a control, the floors were untreated. The two barracks were almost identical in structure, and the men in each lived and worked under closely comparable conditions. The medical officers of units A and B were well known to each other and were able to agree on common standards for the diagnosis of respiratory infection. This was taken to include all cases arising *de novo* which fulfilled either one or both of the following criteria: (1) An upper respiratory

catarrh with obvious local signs. (2) A generalized "influenzal infection" accompanied by pyrexia.

The diagnosis of a respiratory infection was therefore based on objective evidence which, so far as possible, left no doubt as to the nature of the condition. The diagnosis was not made unless there was sufficient reason for supposing that symptoms and signs were due to recent infection. On this ground the following were excluded: (1) Men with chronic bronchitis. (2) Men with cough but without nasal discharge or pyrexia. Such coughs were attributable to excessive smoking, wax in the ears, training exposures to D.M. gas, or various minor causes. (3) Men who developed coryza or pharyngitis following vaccination: this group presented the only real difficulty, since a considerable but approximately equal number of men in the two units showed inflamed throats or a mild degree of coryza at the height of the vaccine reaction.

The proximity of the two units made it possible, if real doubt arose, for both medical officers to examine the man before a final diagnosis was made. In general the matter was not in doubt, since the great majority of respiratory infections were straightforward examples of acute coryza, pharyngitis, laryngitis, tracheitis, acute bronchitis, or influenza. Over the period of observation both units were receiving recruits at intervals of about a fortnight, so that during the 17 weeks of the experiment a large number of men came under review who were experiencing communal barrack life for the first time.

#### Oiling of Floors

In unit A the wooden floors of all barrack-rooms, sleeping-huts, offices, and lecture-rooms were treated with spindle oil at regular intervals. The oil was applied in such a way as to leave an imperceptible film on the surface after thorough impregnation of the wood. Oil treatment of the floors of unit A began in Nov., 1942, and four applications were made at about monthly intervals up to the end of March, 1943. The oil was non-inflammable and caused no unpleasant smell. The best results were obtained if the floors were first thoroughly swept with a stiff broom, then dry-scrubbed, and finally swept with a soft broom before the oil was applied. This was done with old sacking, which was dipped in the oil, squeezed to get rid of excess, and then well rubbed into the floor along the grain of the wood; no excess of oil was allowed to collect or remain on the floor. The surface dried in about six hours, and one gallon of oil was enough to treat about 1,000 square feet of floor space. Second and subsequent applications made at intervals of about four weeks occupied less time than the first; care was again taken to ensure that the oil was thoroughly rubbed in and no excess left on the surface. After treatment the floor was not scrubbed, but was easily kept clean by brushing or occasional mopping with a rag moistened in oil. Within the unit the regimental officers and men welcomed the oiling of floors—a point of some importance. The floors were easier to keep clean, scrubbing being unnecessary, and the presence of dirt on the oiled floors was so readily apparent that the men were stimulated to adopt cleanly habits.

The floors of unit B—the control unit—were left untreated, and in both units careful weekly records were kept of all men reporting sick with a respiratory infection during the 17 weeks ending March 27, 1943.

#### Results

The results are shown in the accompanying Table. It is clear that the weekly rate of new cases of respiratory infection per 1,000 men was consistently lower in unit A, where the floors were oiled, than in the control unit B, where no such treatment of floors was adopted. It is also of importance to note that unit A suffered no major epidemic of respiratory infection, while unit B sustained a severe outbreak of almost epidemic proportions between the middle of February and the first week of March.

#### Discussion

It is not claimed that this is in every respect a perfectly controlled experiment, but the basis of comparison between the two units is probably uniform enough to support the validity of the results. At each unit almost identical conditions prevailed as regards buildings, sleeping-space per man, stress of training, contact with sources of infection outside the barracks, and the standard of black-out ventilation. The units were large (strength 1,300 to 1,700) and yielded obvious respiratory infec-

Table showing Weekly Rate of Respiratory Infections per 1,000 Men in Test and Control Units

Week Ending	Respiratory Infections per 1,000 Men	
	Unit A (Floors Oiled)	Unit B (Control; no Oil on Floors)
5/12/42	4	18
12/12/42	3	27
19/12/42	4	20
26/12/42	2	17
2/1/43	4	47
9/1/43	2	47
16/1/43	8	38
23/1/43	12	45
30/1/43	7	32
6/2/43	11	48
13/2/43	8	58
20/2/43	9	56
27/2/43	12	52
6/3/43	8	48
13/3/43	8	44
20/3/43	5	31
27/3/43	9	20
Weekly average	7	38

tions in sufficient numbers to reduce the doubtful cases to an insignificant proportion of the whole. Another factor of importance was that close collaboration between the medical officers of the two units helped to eliminate extraneous factors which might have introduced error.

The success in curtailing the spread of purely respiratory infections by oil treatment of floors assumes all the greater significance since it is possible that such important diseases of the barrack-room as virus influenza and cerebrospinal meningitis may also be lessened in their incidence by the same simple procedure.

#### Summary and Conclusions

Treatment of wooden floors with spindle oil at regular intervals significantly lowered the rate of respiratory infections in a large military unit as compared with the incidence in a similar control unit, living under comparable conditions, where oiling of floors was not practised.

In the unit where floors were oiled the average rate of respiratory infections was 7 per 1,000 men, as against 38 per 1,000 men in the control unit. During the 17 weeks of the experiment, from the week ending Dec. 5, 1942, to that ending March 27, 1943, no major outbreak of respiratory infection appeared in the test unit; in the control unit an outbreak of almost epidemic proportions prevailed between the middle of February and the first week of March.

## THE DETERMINATION OF BASAL METABOLISM ON OUT-PATIENTS

BY

J. DOUGLAS ROBERTSON, M.D., D.Sc., Ph.D., D.P.H.  
 (From the Courtauld Institute of Biochemistry, Middlesex Hospital)

Measurement of the basal metabolism is not often employed as a routine investigation in this country. One cause may be that most clinics insist that the subjects live in hospital for a few days in order that the test can be carried out at or near the bedside. Such a preliminary preparation is neither popular with the patient nor looked on favourably by the hospital whose beds are already outnumbered by patients requiring urgent medical and surgical treatment. In this paper proof will be given that in fact it is not necessary to use hospital beds for this test and that determinations on ambulatory patients are satisfactory. At the same time certain technical points on the measurement, accuracy, and constancy of the basal metabolism will have attention drawn to them.

The method of determining the metabolism was that of the "closed circuit," the accuracy of which has already been reported (Robertson, 1937). The apparatus used was the Benedict-Roth with recording kymograph. All machines were alcohol-checked

(Barrett and Robertson, 1937), but in addition each is checked once a week by a model whose basal metabolism is in the region of 56 calories an hour.

### Findings

In the tables which follow, an attempt is made to answer some of the controversial problems in metabolism, such as the number of observations necessary to obtain an accurate result, the effect of exercise on the basal metabolism, and the accuracy of determinations on ambulatory patients.

First, 100 patients were studied on two consecutive days, with duplicate readings each of 10 minutes a day; the results are given in Table I. No significant difference was found

TABLE I.—A Study of 100 Consecutive Patients having Two Tests on Two Consecutive Days

	Mean Heat Output (cals./sq.m./hr. $\pm$ $\sigma$ m*)	Significance of Difference, P†
Initial reading .. ..	39.0 $\pm$ 0.75	P>0.4
Second reading on 1st day .. ..	38.9 $\pm$ 0.76	
Basal reading on 1st day .. ..	38.3 $\pm$ 0.76	P<0.001
" " " 2nd " .. ..	36.4 $\pm$ 0.67	

\*  $\sigma$ m is the standard error of the mean. † P (Fisher, 1938).

between the two readings taken on the first day ( $t=0.895$ ;  $P>0.4$ ). There was, however, a significant fall in the basal metabolism on the second day compared with the first ( $t=8.3$ ;  $P<0.001$ ). This finding in addition to a smaller standard deviation on the second day favours a study of the patient on at least two days.

Next, in Table II, are a series of 26 subjects studied on two successive days as before; but on the afternoon previous to the first standard reading two practice tests, of the same

TABLE II.—A Study of 26 Subjects having Two Tests on Two Consecutive Days (but Two Practice Tests similar in Duration to the Basal Tests were carried out on a Previous Afternoon)

	Mean Heat Output (cals./sq.m./hr. $\pm$ $\sigma$ m)	Significance of Difference, P
First reading on first day under basal conditions	36.7 $\pm$ 0.46	P>0.20
Second reading on 1st day .. ..	36.2 $\pm$ 0.45	
Basal reading on 1st day .. ..	35.8 $\pm$ 0.39	P<0.001
" " " 2nd " .. ..	33.9 $\pm$ 0.37	

duration as the actual tests, were carried out. The element of training was thus introduced before the first observation under basal conditions. Despite this, however, a significant fall in the metabolism took place on the second day ( $t=6.4$ ;  $P<0.001$ ). Once again the two first-day readings were not significantly different ( $t=1.34$ ;  $P>0.20$ ). Thus whereas a dummy reading or practice test is often of value in relieving the anxiety of some patients, it cannot replace the test, under basal conditions, carried out on two separate days.

To determine whether the metabolism continued to fall as the number of observations increased, a series of 14 subjects were studied on six successive days; the results are given in Table III. Again a significant fall on the second day was

TABLE III.—A Study of 14 Subjects having Two Tests on Six Consecutive Days

	Mean Heat Output (cals./sq.m./hr. $\pm$ $\sigma$ m)	Significance of Difference, P
Basal test on 1st day .. ..	35.5 $\pm$ 0.96	P<0.001
" " " 2nd " .. ..	33.5 $\pm$ 0.75	
" " " 3rd " .. ..	33.5 $\pm$ 0.80	
" " " 4th " .. ..	33.6 $\pm$ 0.83	
" " " 5th " .. ..	33.5 $\pm$ 0.75	P>0.2
" " " 6th " .. ..	33.1 $\pm$ 0.83	

noticed ( $t=4.07$ ;  $P<0.001$ ). But a comparison of the second day with the sixth day (the days with the maximum disparity, excluding the first-day tests) showed no significant difference ( $t=1.36$ ;  $P>0.2$ ). Thus by the second day a reproducible basal metabolism can be recorded.

The subjects studied above in Table III were normal healthy volunteers (nurses). A similar study was now made on persons suffering from thyrotoxicosis, and these are given in Table IV.

TABLE IV.—A Study of 7 Cases of Thyrotoxicosis having Two Tests on Seven Consecutive Days

	Mean Heat Output (cals./sq.m./hr. $\pm$ $\sigma$ m)	Significance of Difference, P
Basal test on 1st day .. ..	63.2 $\pm$ 3.1	P<0.01
" " " 2nd " .. ..	57.1 $\pm$ 2.6	
" " " 3rd " .. ..	55.1 $\pm$ 1.9	
" " " 4th " .. ..	54.9 $\pm$ 2.2	
" " " 5th " .. ..	55.1 $\pm$ 1.9	P>0.1
" " " 6th " .. ..	54.1 $\pm$ 2.2	
" " " 7th " .. ..	55.1 $\pm$ 2.0	

As with normal subjects, a significant fall in metabolism occurred on the second day ( $t=3.51$ ;  $P<0.01$ ). The fall continued to take place daily, reaching its maximum on the sixth day, but a statistical study showed that this further fall is of no significance. If the second- and sixth-day readings are compared (the days with the maximum disparity in their means) no significant difference is found ( $t=1.73$ ;  $P=0.1$ ). Thus cases of thyrotoxicosis by the second day give a satisfactory and reproducible reading of their basal metabolism.

In Table V the effect of exercise on the basal metabolism is shown. The subjects (12 normal, and 5 cases of thyrotoxicosis) were first studied under basal conditions. After this

TABLE V.—A Comparison of the Metabolism under Basal Conditions with the Same Metabolism following Exercise. After the exercise the subjects lay down on a couch and the metabolism was measured without preliminary rest for the next 40 minutes

No.		12 Normal Subjects		5 Cases of Thyrotoxicosis	
		Mean Heat Output (cals./sq.m./hr. $\pm$ $\sigma$ m)	Significance of Difference, P	Mean Heat Output (cals./sq.m./hr. $\pm$ $\sigma$ m)	Significance of Difference, P
a.	Under basal conditions	35.3 $\pm$ 0.47	a & b < 0.001	55.0 $\pm$ 1.7	a & b < 0.001
b.	0-10 min. after exer.	40.2 $\pm$ 1.06		64.3 $\pm$ 2.8	
c.	10-20 " " "	36.8 $\pm$ 0.50	a & c < 0.01	57.1 $\pm$ 1.6	a & c = 0.01
d.	20-30 " " "	35.7 $\pm$ 0.47	a & d > 0.3	54.7 $\pm$ 1.5	a & d > 0.6
e.	30-40 " " "	35.2 $\pm$ 0.48	a & e > 0.4	55.1 $\pm$ 1.7	a & e > 0.8

reading was taken, they rose, and descended and ascended the steps of the Courtauld Institute (95 steps; distance down, 55 feet) in approximately 24 minutes. In both normal and thyrotoxic subjects the metabolism again became basal after a rest of only 20 minutes.

Finally, a comparison was made between the metabolism measured under strictly basal conditions and that under ambulatory conditions. Full details of the routine carried out by four subjects after rising and leaving their homes for the 'metabolism department' are given in Table VI. Despite in some cases quite appreciable exercise and the exposure to an outside temperature about freezing-point, half an hour's repose on a couch in a room at a temperature of 20 to 23° C. was adequate to reproduce basal conditions.

### Discussion

Different clinics do not appear to have the same system of assessing a subject's basal metabolism. There is no unanimity about the number of tests, the number of daily observations; and whether to report a mean of all results or the lowest reading. In some clinics it is the usual custom to carry out only a single determination without any preliminary practice, thus excluding the element of training (Boothby, Berkson, Dunn, 1936). Those authors, however, add that the initial reading is accepted "unless at the time of the test and before its calculation it was noted as unsatisfactory for reasons of restlessness, observable nervous tension or an elevated temperature." There are several objections to Boothby *et al.*'s technique. First, so-called nervous tension is not uncommon at the initial test, and particularly in cases of thyrotoxicosis. Secondly, initial readings are commonly higher, and sometimes much higher, than subsequent or true basal determinations. Thus in a series of 223 subjects aged 19-156 (70%) gave initial readings which were significantly higher than those on the second day, 48 (22%) gave results 10% or more higher, 21 (9%) gave results 15% or more higher.

TABLE VI.—A Comparison of the Bedside and Ambulatory Estimations of the Basal Metabolism

Name	Surface Area (sq. m.)	Bedside Tests After a Night's Rest in the Metabolism Room at temp. of 20-23° C. (cal./sq.m./hr.)	Ambulatory Tests taken After 1 hour's Rest on a Couch in the Metabolism Room at temp. of 20-23° C. (cal./sq.m./hr.)	Procedure Carried out Before Arrival at the Metabolism Department

and as many as 11 (5%) gave readings as elevated as 20% higher. In no case was the initial reading at the time of the test considered unsatisfactory. The series was a group of nurses who had volunteered for the test. To judge a subject's basal metabolism on only a single observation is to run the risk of reporting a raised instead of a normal metabolism. Thirdly, if standards are based on initial readings then the metabolic assessment of subjects who have ever had the test before becomes difficult. The experience of a test previously means training which Boothby *et al.* suggested should be excluded. Finally, the controlling influence of iodine on the basal metabolism of thyrotoxicosis as a diagnostic test becomes much less sensitive; for, indeed, it would be very difficult to determine whether a fall in the metabolism in a subsequent test after iodine was due to the element of training or to iodine.

In other clinics several readings are taken on one day, and either the mean or the lowest reading is accepted as the basal metabolism. Other clinics prefer observations carried out on several days, and again the mean or the lowest reading is taken as the basal metabolism. As the technique for assessing a subject's basal metabolism appears to vary in different clinics, one must expect some disparity in their respective results.

The findings in this paper are that by the second day of basal conditions, with few exceptions, a reproducible result can be obtained for the basal metabolism of normal people and cases of thyrotoxicosis that is constant over a period of several days at least. It has been the custom in this department, therefore, to adopt a certain technique in measuring and reporting on the basal metabolism: it is the attendance of the subject on two successive mornings after the customary fast of at least 12 hours. After half an hour's rest on a couch in a room at a temperature of 20 to 23° C. duplicate

determinations, each of 10 minutes' duration, are taken. On the second day the results are commonly lower than on the first; but if this is not so, the subject is asked to attend on another morning. On the day with the lowest reading the duplicates are expected to agree within 5% (or attendance on a further day is requested), and the lower of the two readings is reported as the basal metabolism.

It is suggested that the measurement of the basal metabolism in this country is not commonly carried out because insufficient use is made of ambulatory determinations. There is a reluctance to accept results on ambulatory patients because they are believed to be inaccurate. This is an entirely false conception without any experimental evidence to support it. Proof has here been shown that in fact metabolism determinations on ambulatory subjects are as accurate, uniform, and reliable as those carried out at the actual bedside if half an hour's repose on a couch in a warm room precedes the determination. Benedict and Du Bois, in a personal communication, stated this interesting fact many years ago, and their findings were confirmed at that time. It is interesting to note that cases of thyrotoxicosis as well as normal subjects, in so short a period as 20 minutes' rest on a couch, can reproduce basal conditions even after such exercise as walking down 95 steps and up again in 2½ minutes. From a diagnostic point of view it is unfortunate that cases of thyrotoxicosis respond no differently to exercise than do normal subjects. For if, in thyrotoxic cases, half an hour's repose on a couch was insufficient to reproduce basal conditions, the effect of exercise on the metabolism might constitute a sensitive diagnostic test for mild cases of thyrotoxicosis. Attention has been drawn to these mild cases of thyrotoxicosis with a basal metabolism apparently normal yet actually raised (Robertson, 1934). Iodine in conjunction with the basal metabolism will invariably detect these mild cases. In that paper a proved case of thyrotoxicosis was described in which an initial basal metabolism of minus 8 fell to minus 27 on iodine (i.e., minus 27 was normal for the patient, so minus 8 meant a raised basal metabolism).

It is believed that the value of ambulatory metabolism determinations is still insufficiently appreciated in this country. The blocking of a hospital bed for several days for an examination of this nature adds considerably to its cost, and the patient is unwilling to co-operate because of loss of working hours, personal expense, and the like. The results given above indicate that there is no reason why an out-patient should not attend hospital in the morning for the test (approximate time, 1 hour), then return to his ordinary duties for the rest of the day. A test carried out early enough might result in no loss of working hours.

#### Summary and Conclusions

A reproducible metabolism measurement can be obtained if the subject attends for the test on at least two mornings under basal conditions. By the second day of the test, if the duplicates agree within 5%, then the lower of the readings can be taken as that subject's basal metabolism. If the second-day tests are higher than those taken on the first day, then further attendance is advisable until a constant reading is obtained.

The above technique can be applied with satisfaction to normal subjects and cases of thyrotoxicosis.

After reasonable exercise basal conditions can be reproduced after resting on a couch for approximately 20 minutes. A preliminary repose of half an hour before metabolism reading is taken is adequate for basal purposes.

A satisfactory, accurate, and reproducible metabolic reading can be obtained on "out-patients." These so-called "ambulatory determinations" are not significantly different from those tests carried out at the bedside under strictly basal conditions.

The reproducibility of the method described above for measuring the basal metabolism is within 5%.

It is a pleasure to thank Prof. E. C. Dodds for his criticism of this paper and the Government grants for scientific investigation, through the Royal Society, for the gift of a basal metabolism machine.

## NUTRITIONAL OEDEMA IN A VEGETARIAN

BY

J. MacDONALD HOLMES, M.D., M.R.C.P.

*Physician to the Staffordshire General Infirmary and Wrexham and East Denbighshire War Memorial Hospital*

Nutritional oedema has long been recognized as an accompaniment of gross disease of the alimentary tract and of conditions which lead to excessive loss of plasma proteins. It is commonly seen in conjunction with chronic dysentery and other conditions giving rise to chronic diarrhoea. It may be accompanied by symptoms of vitamin deficiency, such as peripheral neuritis or pellagra, and an anaemia of microcytic or macrocytic type is often associated with it.

The chief factor in the causation of nutritional oedema is generally considered to be a hypoproteinaemia, with a consequent lowering of the osmotic pressure of the blood and a disturbance of the balance of fluid distribution between the blood and the interstitial tissue spaces. Moore and van Slyke (1930) state that oedema develops when the total serum proteins fall below the critical level of  $5.5 \pm 0.3$  g. per 100 c.cm.; but other factors, such as the intake and excretion of blood electrolytes, the blood volume, and the presence or absence of anaemia, must also influence the occurrence of oedema, so that it does not necessarily appear when the serum protein content falls below the so-called critical level.

In the absence of gross alimentary disease nutritional oedema is rare in this country, and even vegetarians are able to maintain an adequate protein intake, in spite of wartime restrictions in diet. The case to be described, however, illustrates how a vegetarian diet in association with a comparatively minor gastro-intestinal abnormality may cause a hypoproteinaemia of serious degree, giving rise to symptoms similar to the "hunger" or "famine" oedema which occurred endemically in Europe during the last war and which will no doubt occur again during this war.

## Case Report

The patient, a woman aged 61, was first seen in consultation with Dr. B. A. Abbott, of Rugeley, on Aug. 3, 1943. During the previous few weeks Dr. Abbott had treated her for a severe anaemia by ferrous sulphate and small doses of liver extract intramuscularly. Although the anaemia had practically disappeared she had developed ascites and generalized oedema during the preceding ten days. In 1932 a gastro-enterostomy had been performed for pyloric stenosis due to a chronic ulcer, but no gastric symptoms had occurred since and her health had been good until the onset of the anaemia. She stated that she was an almost complete vegetarian, the only animal foods taken being milk and cheese. For the last eight weeks her appetite had been poor and her intake of milk had been low owing to rationing.

On examination she was pale but not grossly anaemic. Her skin was dry and had a slightly atrophic appearance. She had a red glazed tongue, sore at the tip, and her finger-nails showed a well-marked koilonychia. Gross ascites and a generalized oedema of the whole trunk were present, but oedema was only slightly evident in the face. There was some dyspnoea, and signs of free fluid were observed in both sides of her chest. The pulse rate was 100 per minute, but there was no cardiac enlargement or irregularity. B.P. 140/90. The urine was normal, containing no albumin or casts. Her mental state was normal, and she showed no neurological abnormality. There was no diarrhoea, and the stools were normal in appearance.

She was admitted to hospital for further investigation on Aug. 5. A diagnosis of nutritional oedema had been considered, but the possibility of gastric carcinoma with widespread secondary deposits had to be excluded. Investigations produced the following results: Red count: R.B.C., 3,900,000 per c.mm.; Hb, 72%; C.I., 0.92; W.B.C., 10,200 per c.mm.—polymorphs 76%, lymphocytes 21%, monocytes 3%; slight anisocytosis and poikilocytosis of red cells. Total plasma proteins: 3.3 g. %—albumin 1.98%, globulin 1.32%. Serum sodium 313 mg., serum calcium 8.1 mg., and blood pyruvic acid 0.77 mg. per 100 c.cm. Fractional test meal: complete histamine-fast achlorhydria, with emptying time of 1½ hours. Pleural fluid: 46 lymphocytes per c.mm.; protein 240 mg., chlorides 620 mg. per 100 c.cm. An x-ray film of the chest showed large bilateral pleural effusions. Radiological examination of the stomach and intestinal tract revealed no abnormality apart from the gastro-enterostomy. During the first four days in hospital her urinary output was low, averaging about 600 c.cm. a day, without restriction of fluid intake. She continued her vegetarian diet during this time.

On Aug. 10 the patient was given two bottles of reconstituted plasma intravenously. On the 11th it was noticed that her urinary output had risen to 1,800 c.cm. during the 24 hours and her total plasma proteins to 4 g. %—albumin 2.66%, globulin 1.34%. Two more bottles of reconstituted plasma were given on the 12th, and she was persuaded, with some difficulty, to take a high-protein diet containing ample amounts of animal protein. During the next week the high urinary output was maintained and there was a rapid diminution in the ascites, generalized oedema, and pleural effusions. Her further progress was uneventful, and the ascites, oedema, and pleural effusions had disappeared completely in about ten days. Oral and intravenous glucose-tolerance tests were done on Aug. 14 and 15 respectively, and showed no disturbance of sugar metabolism. She has remained well up to the time of writing, having abandoned her vegetarian diet.

## Comment

Hypoproteinaemia has been classified by Davis and Getzoff (1942) into three types: (1) *Prehepatic hypoproteinaemia*, in which there is interference with adequate intake, digestion, or absorption of plasma-protein building materials. In this type the ability of the liver to form plasma protein is not affected. (2) *Hepatic hypoproteinaemia*, in which there is inability of the liver itself to form plasma proteins, in spite of the fact that normal supplies of protein building material are received from the intestines. This type is usually associated with severe hepatic disease. (3) *Post-hepatic hypoproteinaemia*, in which there is an adequate formation of plasma proteins by the liver but an abnormal loss of plasma protein, as in severe burn or prolonged haemorrhage or suppuration.

The case described was of the "prehepatic" type. The patient's vegetarian diet contained a minimal amount of protein and when her appetite was poor her protein intake was further reduced. The complete achlorhydria no doubt interfered with adequate digestion, and so the plasma proteins fell below the level required to maintain the normal osmotic pressure of the blood. The achlorhydria also interfered with her iron intake and produced an iron-deficiency anaemia.

The treatment of severe degrees of nutritional oedema by a high-protein diet alone may be slow, and it seems reasonable to expect a more rapid response from intravenous plasma transfusions. This expectation was well borne out by the immediate increase in the urinary output after the first plasma transfusion and the rapid disappearance of the oedema.

## Medical Memoranda

## The Use of Cyclopropane in the Field

Shortly before the second battle of Alamein I received, through the co-operation of the D.M.S., M.E.F., Major-General Sir Percy Tomlinson, A.M.S., and the Technical Adviser in Anaesthetics, M.E.F., Major R. W. Cope, R.A.M.C., a cylinder of cyclopropane for use in the forward areas. Since then I have had a small but adequate supply, and I have used it at C.C.S. during the Eighth Army's advance almost to the end of the campaign, at a field surgical unit for the Sicilian campaign and also for four months in Italy, from the landing at Salerno onwards. I think it is now possible to make some assessment of the value of cyclopropane for the type of case operated on at casualty clearing stations and field surgical units.

Approximately 1,200 cases were anaesthetized by me during this time. Pentothal alone was the drug used in 80% of the cases; cyclopropane, with or without the addition of nitrous oxide or occasionally ether, in 10%; local anaesthesia in 5% and intravenous morphine in 5%. The cyclopropane was reserved for the penetrating wounds of the abdomen, the thoraco-abdominal wounds, and those few cases which were regarded as very bad risks and had failed to respond to resuscitative measures. It was found to be of great value in all the cases.

## THE PROCEDURE

*Penetrating Wounds of the Abdomen.*—Most cases were already adequately morphinized, and no further premedication was given. They almost all came to the theatre with a slow blood drip going, and induction was usually effected by injecting 0.25 g. to 0.5 g. of pentothal. Intubation was done as

outine in the early cases, but later it was found that many cases could be managed perfectly well without, and it was only one in those that presented special difficulties. The ease of control of the depth of anaesthesia, the quiet respirations, and the good oxygenation were features that were appreciated. No difficulty was experienced in obtaining adequate relaxation. Patients recovered quickly after operation, and their cough reflex was usually present before they left the theatre.

**Thoraco-abdominal Wounds.**—The same procedure was followed in these cases, except that intubation was done as a routine. Controlled respiration was used when necessary.

**The Very Bad Risks.**—Anaesthesia in these cases was effected with nitrous oxide and a high percentage of oxygen. Cyclopropane was added if necessary.

**General.**—The machine used was a Rochester Lundy Heidrink. It has travelled many hundreds of miles over bad roads and tracks, and has been packed and repacked many times without damage. Two hundred and seventy gallons of cyclopropane have been used for 120 operations. The economy in cylinders thus effected is most striking. If semi-closed nitrous oxide, oxygen, and ether had been used in these cases about 120 100-gallon cylinders of nitrous oxide would have been required instead of the three cylinders of cyclopropane of the same size.

#### CONCLUSIONS

Cyclopropane was found to be of great value for penetrating wounds of the abdomen, thoraco-abdominal wounds, and bad risks.

A modern anaesthetic machine will stand up well to the constant moves and rough usage encountered in the field.

The economy in material effected by the use of the carbon dioxide absorption technique is demonstrated.

It must be emphasized that the circumstances which enabled me to be supplied with cyclopropane were unusual and that difficulties of supply would preclude its use on a large scale.

Major, R.A.M.C.; Anaesthetic Specialist  
to a Field Surgical Unit.

### Expectation of Life after Nephrectomy for Urinary Tuberculosis

The following cases which reported to me simultaneously last Christmas may be of use to those who are asked for prognosis in urinary tuberculosis:

#### CASE HISTORIES

**Case 1.**—A lady was sent to me from Singapore 45 years ago with a grave prognosis of urinary tuberculosis. The presence of tubercle was confirmed. On cystoscopy I found the right ureteral orifice dragged away from its angle in the trigone and recognized that I was dealing not with a vesical tuberculosis but with tuberculosis of the right kidney and ureter. I removed the right kidney, which proved typical of the disease, but left the lower part of the thickened right ureter. This lady has reported yearly to me since then. She has married twice, and the son born subsequent to the operation joined the R.A.F. She is now 70, and though feeling the limitations of her age, is happy, free from pain, and moderately active.

**Case 2.**—Twenty-seven years ago I was consulted about an abdominal attack in a male case which I diagnosed as being due to disease of the appendix. The right epididymis was tuberculous and suppurating, and the patient had a small hard deposit of tubercle in the right prostatic lobe. On opening the abdomen I found the appendix normal, but the entire peritoneal surface was subacutely inflamed and the mesenteric glands were very large and obviously inflamed. I closed the abdomen without drainage. As the patient had tubercle bacilli in the urine, and cystitis, I gave a very grave prognosis; but he recovered, healing normally. He went to the South of France, and after a year or so (1920) my friend Prof. Wildbolz of Berne removed his right kidney. Later on he had cystotomy performed in Mentone and an "ulcer at the neck of the bladder scraped." Eventually he returned to London, and Sir J. Thomson-Walker punched out with a cupping forceps the deposit in the right prostatic lobe. This patient reports to me frequently. He is now 70, very active and without urinary symptoms, and able to enjoy life and take part in the social activities of a large provincial town.

Here are two cases of confirmed urinary tuberculosis, both pointing, I suggest, to the renal origin of the disease, and both relieved by removal of the focus in the kidney.

Consulting Surgeon, and at one time Professor  
of Urology, at the London Hospital.

## Reviews

### FEEDING BRITAIN

*Achievement in Feeding Britain.* By Gerald Bullett. (2s. 6d.) London: Pilot Press.

This is No. 5 of the "Achievement Books" which the Pilot Press are publishing. The series is under the general editorship of Mr. Noel Carrington. In his short foreword to this book Mr. Carrington says—truly enough—that the health of the nation has not only been maintained but in many instances actively improved during this war, in spite of severe rationing. Here the overworked general practitioner ironically comments: "In many instances, yes; but in many more instances the boot is on the other foot." Mr. Carrington, however, resuming his exordium, says: "So perhaps we should not only thank God with our daily grace before and after meals but occasionally pay a tribute to the almost miraculous work of those responsible for bringing us our rations—the seamen, the farmers, the dockers, the railway men, the shopkeepers; and, behind them all, the staff of the Ministry of Food." The suspicion of the cynical reader grows, in spite of the truth, justice, and good feeling of every sentence that Mr. Carrington writes—taking exception, possibly, to his grammar. But, to resume. Like the other works issued by the Pilot Press this is well printed on good-quality paper, and is illustrated on every page by one or more photographic reproductions, including several in colour, practically the whole of the photographs being supplied by the Ministry of Food—the hero of the book. The illustrations are most varied, though one misses a portrait of the author himself, who, after all, does the real work of this brochure. Still, nearly everything else is illustrated. There is a very nice portrait of a thrush dropping grubs into the wide-open mouths of its tiny nestlings, in their natural surroundings; while other pictures show a meeting of the Scientific Advisory Committee with Sir J. C. Drummond at the Ministry of Food; a land girl leading a bull to fresh quarters; miners and their families working on their allotments outside the pit-head; and a civic restaurant at Kingston with customers seated at the tables and the walls decorated by young artists. We have a photograph of the King studying a chart with Lord Woolton at headquarters, and one showing the contrast of "potatoes in plenty in 1943" with potatoes in scarcity in 1917. Lord Woolton has been called upon to preside over a difficult enterprise in which few men would have succeeded one-tenth as well as he has—thanks largely to his wise choice of scientific and other advisers, and his wisdom in knowing when wholly to follow their advice, when to follow it subject to modifications, and when to reject it altogether. But we must remember that "even Homer nods," even Socrates made mistakes, and the wisest doctor whom Harley Street has ever produced occasionally finds his diagnosis and prognosis disproved in the pathological laboratory and the post-mortem room. And the Minister of Food must not be confused with the Ministry of Food; nor must either be confused with "the Government."

One thing, however, is certain. Whoever is responsible for the choice made no mistake in getting Mr. Gerald Bullett to write this summing-up of the facts put before him. Mr. Bullett is known to a large part of the educated world as a poet of distinction and one of the finest and most tasteful of anthologists, his only serious English rivals being Sir John Squire, the Viceroy of India, "Q." G. K. A. Bell, and the Secretary of the Society of Authors. This gives considerable authority to any work of this kind that he may undertake; and we can be quite sure that, like Lord Woolton himself, he will obtain his facts from the best-reputed and most authoritative sources, and that he will bring both taste and common sense to the summing-up of these "scientific statements." Of course, even after all this care has been taken and this pictorial splendour has been laid before us, many of us, not the most thoughtless or nationally insoucious, will occasionally raise our eyebrows and think twice before swallowing everything holus-bolus. Here, for instance, are a few memories of my reading and observation that give occasion for pause.

J. C. McClelland (*J. Urol.*, 1944, 51, 1944) records the case of a man aged 42 who was given sulphathiazole gr. 30 and sulphapyridine gr. 150 for acute otitis media in 48 hours. He developed anuria and died early on the seventh day. The pathological findings were not marked, nor did they seem to be sufficient to cause anuria and death. The ureters were not blocked with crystals.

Most readers of the *B.M.J.* are familiar with the name of Hindhede, the celebrated doctor who dealt with the Danish food problem in the last great war. In his book, *Protein and Nutrition*, which was published in Danish in 1906 (when he was studying this problem), he refers to the Sikhs. He agreed with most people that taken as a whole the Sikh is one of the finest types of man to be found in Asia; is independent without being insolent, resolute and firm in character, and remarkably free from petty bias and prejudices. "He respects himself, and, as a result, commands the respect of others; he is a soldier by instinct and tradition, regards cowardice as worse than a crime, and, with his splendid physique and well-ordered ways, is one of the finest of Oriental races." Yet he says that the ordinary trained Sikh takes only two meals daily—morning and evening—and has meat only twice a month. (Dr. Hindhede says that the diet corresponds very nearly with that which has been used for years in his—the author's—home "and it has been found to be ample for our needs. Stomach disorders are unknown to us, and we are unacquainted with scurvy except by name.")

Then again some of us will recall a book entitled *The People's Food*, published a year before the present war started, the author being the "Advertising Practitioner" (his own description of himself), Sir William Crawford. His book is a very interesting one, written only in part for the welfare of the community at large if we remember that the community is composed of individuals, but full of sensible and helpful ideas. Here, perhaps, is his main conclusion:

"To handle the food problem of the future a Food Research Institute is necessary—on which all those interested in health, nutrition, food, are represented. It would direct research into such problems as those quoted from the first report of the Advisory Committee on Nutrition. It would carry out economic investigations and surveys regarding food consumption and the food market. It would take the lead in setting new standards of purity and quality in food, as Lord Horder, in his presidential address to the Royal Institute of Public Health, in the previous year, advocates to safeguard public interests. It would handle schemes of educational propaganda to direct food consumption into the most valuable channels, schemes which would form the background to advertising campaigns for specific foodstuffs which producers and manufacturers might themselves launch. It would be at the service of those statesmen, those health and medical officers, those social workers, and those producers referred to in the opening chapters of this book as being so specially in need of a full understanding of the food market."

Such a machine is necessary to carry a new policy into action. The policy itself is plain. Just as last century the advocates of preventive medicine fought the battle for proper sanitation, so this century they will fight the battle for proper nutrition. Just as to-day sound drains and clean water are the *sine qua non* of civilized life, so will a proper diet come to be regarded as the necessity of all classes of the community.

My memories call up ideas and criticisms in book after book in my library. There is *Health and Longevity through Rational Diet*, written by Dr. Arnold Lorand of Carlsbad, the quotation on the title-page being from Brillat-Savarin: "Tell me what thy food is, and I will tell thee what thou art." Another very interesting little book is one with a cardboard cover—*Cookery without Flesh*, printed and published in 1818, in which perhaps the most relevant section is the one on bread and bread-making. In this chapter it is stated that "the most wholesome bread is made by grinding down whole grain, only separating the coarser bran; or what is called meslin bread, consisting of wheat and rye ground together." I and many other people wish the deivers of the present national bread had insisted on only the coarser part of the bran or husk being removed, leaving the living germ immediately under the outer husk intact. That, of course, entirely alters the food adequacy, the tastefulness, and the moisture-retaining quality of the bread—reminding one of the old farmhouse bread. But, of course, it would not suit the miller so well, as the flour does not "keep" so long.

In conclusion, I strongly advise every reader of the *B.M.J.* who has time to read anything else, at all to buy, beg, or borrow Mr. Bullett's first-rate introduction to a really important subject with which all doctors are, or ought to be, concerned.

HARRY ROBERTS.

## CLINICAL PARASITOLOGY

*Clinical Parasitology.* By C. F. Craig, M.D., F.A.C.S., F.A.C.P., and E. C. Faust, M.A., Ph.D. Third edition, thoroughly revised. (Pp. 767; illustrated. 45s.) London: Henry Kimpton. 1944.

The fact that a third edition of this book has been called for in the space of seven years is a sufficient indication of its high value. The present edition has been thoroughly revised and the various sections brought up to date. A perusal of the contents shows that very little has been left out. The new edition contains 40 new figures and four coloured plates illustrating malarial parasites. These greatly enhance the value of the book, which still remains the best one available on the subject of clinical parasitology, meaning by this the morphology and life-history of organisms in the fields of protozoology, helminthology, and entomology which are responsible for producing disease in man, the methods of their identification, the pathological conditions they produce, and the means of treatment and prevention. The book will be chiefly of use to laboratory workers in the field of tropical medicine, whether at home or abroad, and it should be available to all who are called upon to investigate cases of sickness in those who have been exposed to tropical infections.

The book is profusely illustrated, and for this reason it is perhaps a pity that the spirochaetes of relapsing fever in blood are not figured, and that there is no illustration of toxoplasma, which is attracting an increasing attention. The subject of rat-bite fever might with advantage have received some notice. However, these are minor matters that can hardly detract from the excellence of the book, which is of special value at the present time.

## RED CROSS WORK IN CHINA

*The Red Cross at Work in China.* Published on behalf of the United Aid to China Fund (57, New Bond Street, London, W.1.) at 1s. Compiled by F. M. Osborn.

This little book consists chiefly of extracts from letters written by Dr. R. B. McClure, a Canadian medical missionary, born and reared in North China—a graduate in medicine of Toronto University. Soon after Japan attacked China he became first director for the International Red Cross, with supervision of staff and equipment in 14 hospitals throughout North and Central China. After much adventurous service he flew to England in 1938 to inspire interest in China and to raise funds for the organizations helping the wounded and distressed. He found ready and willing help from the British Fund for Relief of Distress in China, the British Red Cross Society, and other organizations now co-operating as the United Aid to China Fund, of which Lady Cripps is president. Before returning to China in 1938 Dr. McClure made a quick trip to Canada and the United States to arouse sympathy there. This little book is well written. It gives a faithful account of all the difficulties that had to be overcome in taking relief to China in her struggle against Japan. It is evident that splendid work has been carried out by the Red Cross, notably by the Friends Ambulance Unit, staffed by British personnel and financed by America—ambulances, a mobile workshop, and two vehicles forming a mobile surgical unit, one containing a miniature theatre and the other an x-ray plant. They were shipped direct to Rangoon and taken to China with great difficulty over the Burma Road. Later in the year the British Foreign Office made a grant of £50,000 for this ambulance relief work. With the help of many photographic illustrations and interesting descriptions in Dr. McClure's letters we are able to visualize the splendid character and courage of the Red Cross work that has been done for China. There was no need of such aid, and ample evidence is shown of the deep appreciation of Chinese wounded soldiers and the many thousands of pitiful refugees. From beginning to end the work is full of human interest. The book is published on behalf of the United Aid to China Fund, and all the surplus after paying for paper and printing, goes to that fund. It is well worth a shilling.

## Notes on Books

Mr. HAMILTON BAILEY'S *Demonstrations of Physical Signs in Clinical Surgery* first appeared in 1927, and has now reached a ninth edition. It is published at Bristol by John Wright and Sons; price 25s. Readers who are familiar with the eighth edition will recall that it was necessary to replace all the illustrations, the blocks and originals of which were destroyed by enemy action. By introducing a number of new pictures and replacing old ones the author and his publishers have tried to improve the work still further. Some parts of the text have been recast; others have been rearranged and correlated more closely with their appropriate pictures.

*Physical Treatment of Anterior Poliomyelitis*, by DIANA B. KIOO, C.S.M.M.G., is published at 6s. by Faber and Faber. A hearty welcome may be extended to this little book, in which the modern principles and methods of treatment of the paralysis of acute poliomyelitis are expounded clearly and with adequate detail. We may hope that it will find its way into the hands of all who have to administer this treatment, and that it will sound the knell of the old and ineffective methods of "rubbing" and "electrical treatment" that for so long have passed muster as treatment in this disabling malady. The only criticism, and this a minor one, that must be made is that the various paragraphs dealing with pathological and clinical aspects of poliomyelitis and other affections of the nervous system, for which the methods described have value, are not always accurate. Disseminated sclerosis is *not* an extrapyramidal system disease, and to speak of "emotional centres" in the brain is to confuse categories. The book would be the better if this aspect of it were submitted to a neurologist for amendment in any future editions.

The second edition of *Gas-and-Air Analgesia*, by R. J. MINNITT (Baillière, Tindall and Cox; 5s.), remains appreciably the same as the previous one. The book is a short but clear exposition of the principles and practice of gas-and-air analgesia in labour, with particular reference to the author's apparatus. It is written primarily for midwives, but it has its lessons, too, for doctors and others who have the comfort and welfare of the parturient woman at heart.

## Preparations and Appliances

A PORTABLE WARMED ETHER-AND-AIR  
ANAESTHETIC APPARATUS

Dr. A. MEREDITH MILLAR writes from Colwyn Bay:

The object in designing this apparatus was to provide a machine which would be easily portable and deliver a warm mixture of ether and air, the concentration of which could be changed rapidly or maintained the same for a period of time, and to ensure that the mixture would arrive at the face warm. It was to be simple so that any anaesthetist could use it. It was hoped it would allow anaesthesia to be maintained at any level.

The apparatus consists of two bottles, each fitted with a drip feed, which is controlled by a needle valve; a quart vacuum flask: a U-tube of 3/4 in. diameter copper tubing, with one end open to the air and the other having a one-way directional valve permitting air to be drawn through the tube but not returned; a short length of rubber tubing (3/4 in. diam.); a face-piece and expiratory valve.

**Action.**—The vacuum flask is filled with hot water, and the U-tube immersed in it. Ether is put in one bottle and vinesthene anaesthetic mixture into the other. Either of these is fed into the U-tube, where it drops into the hot metal and vaporizes, mixing with the air, which has already become warm while in the U-tube. This mixture is drawn in by the patient. As the ether lands on the hot tubing it makes a hiss, which is easily heard, thus indicating the rate of flow. This varies with each case and as the case goes on. To ensure that too great cooling does not take place before the mixture reaches the patient's face, the length of tubing used is not more than 12 in. long.

**Induction.**—Induction is usually smooth and completed in 3 to 5 minutes as a rule. Vinesthene anaesthetic mixture is used to induce as it gives quicker and smoother induction than ether, particularly where premedication has not been adequate. The change over is made by the gradual addition of ether and reduction of V.A.M.

**Maintenance of Anaesthesia.**—When the desired level of anaesthesia has been reached it is easily maintained and alterations in depth are quite simple. If anaesthesia has become too light, it is noticeable that it may be deepened without coughing, as would occur with open ether. In fact a lighter plane of anaesthesia may be maintained. The temperature of the water when starting the anaesthetic was 190–200° F, which gradually

dropped as anaesthesia proceeded. During this time the face-piece, expiratory valve mounting, and rubber tubing all warmed up, so that the mixture was still at about body heat, as it had been at the start. In most cases the water kept warm enough for 1½ hours' use, allowing as many as four operations to be performed without a change of water being necessary. The time it lasted warm depended on the amount of ether required to anaesthetize the patient.

**Economy.**—From this last observation a saving of ether might be expected, and this was borne out in practice. The average for my series of unselected cases was 6.43 oz. an hour. The following are the figures for the first 58 cases that I did: Average age 33½; average induction time 4½ min.; average time of anaesthesia 27½ min.; average amount of ether per case 3.02 oz.; average amount of V.A.M. per case 0.39 oz.; 38½% of the patients vomited. Premedication was usually with morphine, atropine, and seconal.

**Disadvantages and Advantages.**—The slowness of induction as compared with N<sub>2</sub>O or cyclopropane is a drawback. It can partly be overcome with practice and if economy of V.A.M. is not considered. The main advantages of the apparatus are the smooth anaesthesia and good post-operative condition of the patient; its ease of portability and use; the fact that an intratracheal anaesthesia may be given with such a simple apparatus; and its economy. For a head operation the apparatus can be placed so that it is not in the way and the anaesthetist can also be well away from the field of operation, because not only can the drops of ether be heard at the air inlet but the breathing also. The patients have a feeling of well-being which surprises and pleases them, and the hospital staff are also pleased at the reduction in their work.

I should like to thank Mr. D. I. Currie, Mr. H. Lord, and Dr. F. J. Bennett for allowing me to use this apparatus when anaesthetizing their patients.

## SULPHAMEZATHINE SODIUM

Imperial Chemical (Pharmaceuticals) Limited now offer their "sulphamezathine" brand of sulphadimethylpyrimidine in the form of a stable solution of the sodium salt for intramuscular and intravenous administration. It is available in ampoules each containing the equivalent of 1 g. "sulphamezathine" (in 3 c.c.m.) packed in boxes of 6 and 25.

## PROTEOLYSED LIVER

Allen and Hanburys Ltd. announce that supplies of this product are now available for the oral treatment of patients suffering from pernicious anaemia or other megalocytic anaemias. It has a pleasant flavour and can be administered by dissolving in soup or warm water. 1 oz. of proteolysed liver A. and H. is equivalent to 8 oz. of fresh liver. Available in two sizes, 4 oz. and 8 oz.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MAY 6 1944

## CROSS-INFECTION BY DUST

Next to chemotherapy the study of cross-infection has been perhaps the most notable feature of medical progress during the war, and it is a study in which this country has led the world. The proof that one patient has infected another often depends on the closest possible identification of the micro-organisms recovered from each of them, and is therefore possible in infections due to common species only when these are divisible into many serological types. Unfortunately from the point of view of specific immunization, but very fortunately for the purposes of epidemiological study, there are two important species of which this is true. Just as the serological typing of the pneumococcus is a product almost entirely of work in the U.S.A., so that of haemolytic streptococci—apart from the broader method of grouping devised by Lancefield—is entirely the work of an Englishman. No survey of this subject is complete without a tribute to the work of the late Frederick Griffith, to which the achievements of others in tracing the migrations of haemolytic streptococci are entirely due. The knowledge so gained of cross-infection, particularly in surgical wards dealing with wounds and burns, and in E.N.T. and fever wards, has posed a problem to which the answers are still being found, though many have yet to be applied. It is an indication of the importance attached to this subject that two of the M.R.C. War Memoranda are devoted to it, No. 6 dealing solely with the problem as it affects surgical wards, and No. 11, published and reviewed in these columns only a few weeks ago,<sup>1</sup> embracing cross-infection of all kinds.

There are two principal ways in which cross-infection can occur: through the air and by contact, either direct or indirect. The second of these routes embraces every kind of failure in aseptic technique, including some which were unsuspected until recently and unprovided for in usually accepted rules. By no means everyone yet appreciates the infectivity of a patient's skin at some distance from his wound, of apparently unsoiled outer dressings or of the outer surface of a soiled plaster, or the capacity of haemolytic streptococci for survival on all manner of objects used by an infected patient. On the other hand, an even more striking fact brought fully to light only in the past three years is the degree and persistence of infection in ward dust. All observers who have studied this quantitatively agree in their findings that dust from wards where

there are patients with haemolytic streptococcal infections may contain hundreds of thousands or even millions of these organisms per gramme. They are also known to survive in this medium for long periods: while a substantial number will certainly survive under favourable conditions for a month; a few survivors in naturally infected dust kept in the dark have been observed by L. P. Garrod<sup>2</sup> after a lapse of over six months. The production of such dust is still something of a mystery even to those best acquainted with it. It consists mainly, as does all domestic dust, of particles of wool or cotton, and many of these are evidently contaminated with infected wound exudate or throat secretion. However produced, it remains an obvious menace, accentuated whenever it is scattered into the atmosphere by bed-making or floor sweeping. One important question which remains unanswered is how much cross-infection in the average ward is due to dust and how much to some form of contact. In other words have we to concentrate on purifying the ward atmosphere or on improvements in aseptic and general nursing technique? This is by no means easy to answer, as may be gathered from a careful study recently made by Edward. This comprised quantitative bacteriological examination of dust at intervals of a week for six months in two wards one for E.N.T. and eye cases and the other a children's ward, together with regular swabbing of throats and any septic lesions in the patients and staff. The numerous haemolytic streptococci recovered were typed, and the types found in the dust were usually those with which one or more patients were known to be infected. On the other hand, there sometimes appeared in dust a fresh type which had not been isolated from any patient, presumably having been introduced from without by a patient attending for a dressing. In spite of this very close method of observation, and of the occurrence of numerous cases of hospital infection, no conclusive evidence was obtained of its transmission by dust.

Perhaps the clearest evidence hitherto forthcoming of the proper apportionment of blame to dust and contagion respectively, at least in one type of ward, is to be found in the paper by Joyce Wright, R. Cruickshank, and W. Gunn in this issue of the *Journal*. There is, as is now well known, one method of dealing with the dust danger which can be applied anywhere, regardless of hospital structure or the absence of up-to-date cleaning facilities: and this is the use of oil to make dust particles sticky, so that they undergo agglutination on the floor instead of remaining easily dispersible in the air. This treatment was applied with the utmost thoroughness, not only to the floor—which alone was almost without effect—but to almost every fabric article in the ward, notably the bedclothes and the patient's garments. An identical ward, also accommodating patients with measles, was not so treated. In the oiled ward total counts of bacteria and haemolytic streptococci in the air during bed-making and sweeping were reduced by about 91 and 98% respectively, both from counts previously obtained in the same ward and those which continued to be obtained in the control. The in-

<sup>1</sup> *Brit. Med. J. (Gen. Pract.)*, 1944, 1, 477.<sup>2</sup> *British Medical Journal*, 1, 245.  
<sup>3</sup> *J. Hyg.*, 1944, 43, 256.

dence of infection by the Type 6 haemolytic streptococcus then prevalent in both wards was only 18.6%, whereas in the control it was 73.3%, and the frequency of otitis media was 2.8%, as against 14.3% in the control. This is clear evidence that under these conditions dust is a major factor in cross-infection, and the demonstrated infectivity of various ward articles can account for only a small fraction of the troubles to which such wards are subject. Valuable as this evidence is, it should perhaps be accepted as applicable only to wards for infections confined to the respiratory tract. Where wounds are concerned, contact may possibly play a greater and dust a lesser part, although it is hard to believe, in view of these very definite findings, that dust can ever be unimportant.

This paper is one of three which deal with different aspects of the same subject. That the oiling of floors alone may be useful in living-rooms as distinct from hospital wards is evident from the interesting experiment made by Lieut.-Col. Anderson and his colleagues in two Army barracks. Floor oiling in one of these was accompanied by a striking diminution in the frequency of respiratory infections, and the significance of the figures obtained seems unquestionable in view of the care evidently taken to provide an exact control, and to observe and record in both units according to the same plan. That those responsible for cleaning liked oiling as a system, apart from its benefit to health, is an encouraging fact. A third paper is by three members of the staff of the British Launderers' Research Association Laboratories, who were invited to study the oiling of fabrics with a view to devising an economical process which would be feasible in any laundry. In this they have well succeeded, since it appears that by adding a small amount of a cationic detergent the oil in an oil-in-water emulsion can be caused to be wholly absorbed by wool. Blankets can thus be impregnated with any desired amount of oil, leaving a fluid from which no surplus oil has to be recovered. Cotton requires somewhat more complex treatment, but on the same principle. If, as seems probable, this process comes to be recognized as an essential safeguard in many hospital wards, these authors' instructions will no doubt be widely followed in the future.

---

## THE HEALTH OF MALTA

From the outbreak of war with Italy till the grand release of 1943 the brave people of the Maltese Islands suffered grievous destruction of their property and the increasing privations of a state of siege. During the "prolonged and prodigious" bombardments, when alerts sometimes ran on for forty-eight hours at a stretch, nearly the whole population had to resort to shelter life. Even in the rare periods of comparative quiet they were obliged to live under grossly overcrowded conditions because so many homes had been shattered. The hospitals suffered badly, and emergency services were in constant operation. In addition to anxiety and ever-present danger there was a progressive deterioration of the simple conditions of everyday life. The water supply and the sanitary services were damaged again and again. The preparation of meals was

beset with difficulties, as the essential services of electricity and gas were frequently cut off. As time went on, food rations, as well as allowances of soap, water, and fuel, had to be curtailed. It was hard to maintain bodily cleanliness. The calorie value of the diet dropped to a dangerously low level as the siege became more severe, and fresh protective foods such as eggs, milk, and butter were practically unobtainable. Fresh meat, mainly from goats and horses, was reserved for hospitals, and all milk was strictly rationed to those in urgent need. The people in general subsisted on vegetable soup, some tinned meat or fish, and a little fat, oil, and beans.

The reports of the Chief Government Medical Officer for the years 1941 and 1942 tell a painful but triumphant story of suffering and loss patiently borne until the day of victory. It is not surprising that there was a heavy mortality at the extremes of life, and the health department had to contend with a high incidence of typhoid fever and disturbing outbreaks of dysentery. Unhappily all the conditions favouring the spread of tuberculosis were present, and the disease took full advantage of its opportunities. The mortality from pulmonary tuberculosis rose from 437 per million in 1939 to 843 in 1942, and the non-pulmonary death rate showed a corresponding increase from 133 to 431, giving a total tuberculosis death rate of 1,274 per million persons living. Scarcity of soap favoured the spread of scabies and other clamorous infestations, but these were quickly controlled when services and normal supplies were resumed. The general prevalence of infectious disease was not so great as might have been expected from the wretched conditions of living, but unhappily a sharp outbreak of acute anterior poliomyelitis occurred in the winter of 1942-3, represented by over 400 cases. There have always been sporadic cases on the islands, but this is the first instance of an epidemic. The restriction of food supplies told a plain story. Loss of weight, especially in children, was much in evidence in the later stages of the siege, and there were a few cases of nutritional oedema and rickets. Septic conditions of the skin, ulcerative stomatitis, and other signs of vitamin deficiency were unmistakable, and scurvy appeared among the old. There was a moderate amount of pellagra. These conditions improved rapidly when the siege was raised.

The medical and health department of the Maltese Islands never faltered in the time of trial. The services were carried on in the face of fearful odds, when the added burden of emergency medical services strained the resources to the utmost. The people of Malta have received the George Cross as a worthy token of their courage, but the time is approaching when a more substantial recognition is due. Among the many ruined homes there were slums and unhealthy houses; standards of family life often fell short of the decency and order of a flowering civilization. The great disaster must be turned to greater advantage by building good homes in well-designed towns, "with amenities that would render existence more useful and more pleasant both to the individual and to society as a whole." The Chief Medical Officer rightly adds that it will be a far-reaching tragedy if this unique opportunity is lost.

## BIOLOGICAL VALUES OF MIXED PROTEINS

It has been realized for at least twenty years that a mixture of proteins may have a higher biological value than that of the separate proteins in the mixture;<sup>1,2</sup> and that a relatively small addition of animal protein may considerably raise the biological value of a predominantly vegetable diet. This supplementation occurs when one protein contains an adequacy of one or more amino-acids in which the other proteins of the diet are deficient. For example, gelatin—a protein which itself has an extremely low biological value, since it is completely devoid of several essential amino-acids—has three times the lysine content of wheat proteins, and hence when mixed with the latter produces a mixture better able to provide the body's amino-acid needs—i.e., is of higher biological value than the wheat protein alone.

Very few reports illustrating the working of this principle in practical European diets have been published, no doubt owing to the considerable technical difficulties in the collection of representative meals and in the determination of biological value. The recent paper of Macrae, Henry, and Kon,<sup>3</sup> on the proteins in food served in R.A.F. messes is of special interest in this respect. At each of four R.A.F. stations the total food available to five men at all meals during one week was collected by taking plates at random from the men as they left the serving table. The food was frozen to  $-20^{\circ}$  for a week and homogenized in the frozen condition. The biological values and true digestibilities were determined by giving each diet (slightly diluted to equalize the protein and fat content) in turn to each member of a group of young growing rats and measuring their growth rates and nitrogen balances. Significant differences were found in the biological values and digestibilities of each protein, though all were high, the extreme figures for biological value being 77.6 and 81.2. The protein values of the diets—that is, the product obtained by multiplying biological value, digestibility, and level in the diet,<sup>4,5</sup>—also showed variations, values of 9.5, 11.1, 11.1, and 12.2 being obtained for the four diets. Only three single foodstuffs are known to have biological values greater than those found for these mixed proteins. One of these foods, eggs, was absent from the R.A.F. diets; the second and third, milk and white fish, each contributed a mere 5% of the total proteins. The animal protein was calculated by Macrae *et al.* to be about 43% of the total protein of each diet. Hence the inclusion of 57% of vegetable protein had raised the biological value of the mixed protein to a figure higher even than that of the majority of the individual animal proteins.

These experiments were carried out in October–December, 1941, but the protein position of both civilians and Services has been improved since National flour became compulsory early in 1942. The experiments of Chick,<sup>6</sup> though contested by Wright,<sup>7</sup> are generally accepted as showing superiority in biological value of the proteins of National over white flour. In the R.A.F. diets studied only one-third of the flour, providing 6 to 10% of the total proteins, was of the National variety. Assuming that these determinations of biological value based on rat experiments are applicable to man, it would seem that with the amino-acid contribution of National flour supplementing the other sources of amino-acids in the diet, there need be no qualms about the protein value of our diet during the fifth year of war.

## A SHORT GUIDE TO V.D.

When general practitioners were asked to undertake the treatment of venereal diseases under the Ministry of Health's scheme it was obvious that they would need some guidance. This was provided in a little pamphlet issued by the Ministry of Health and the Department for Scotland entitled *Venereal Disease: Guide for Practitioners* and drawn up by Col. L. W. Harrison. The name of the author is a sufficient guarantee of the quality of the contents, and it can be said at once that it seems hardly possible that this pamphlet could be improved. In fewer than 20 pages is compressed almost all the average general practitioner would want to know about the job he has been asked to undertake; particularly clear are the sections on the taking of specimens and the interpretation of reports of serum tests. These two matters are of paramount importance when one realizes how essential it is that the diagnosis of syphilis, with all that it entails, should be made only on almost incontrovertible evidence. Diagnosis, treatment, and tests of cure are set out with the utmost clarity, and sections are included on equipment, sterilization, and care of solutions and instruments, and in an appendix appliances and drugs required. If any criticism is to be made it would seem that: (1) Four gonococcal complement-fixation tests in three months after completion of treatment of gonorrhoea are rather excessive; (2) the taking of a specimen of prostatic and vesicular secretion one week after apparent cure is rather early when a case has cleared up in a few days under chemotherapy; and (3) irritating the urethra by instilling Lugol's iodine as a test of cure would not appeal to all venereologists. Further, it might be useful to explain how to dissolve neo-arsphenamine preparations—i.e., by sprinkling the powder lightly on to the distilled water, not by pouring the distilled water on to the drug. This is an excellent publication, with the stamp of quality all over it; those who treat venereal disease should study it carefully. Copies may be obtained through the M.O.H. of the county or county borough.

## MISLEADING NAMES

It is clear from correspondence in this *Journal* that the word "mitis" applied to diphtheria bacilli, and, by extension, to cases of the disease, has some tendency to mislead the general practitioner. The Leeds workers who first used the term could readily separate the cultures got from undoubted clinical cases of diphtheria into three broad groups. "Gravis" was mainly found in severe infection with toxæmia, bull neck, and a high incidence of paralytic and cardiac complication; it gave a characteristic colony on heated blood agar and tellurite plates, and fermented starch and glycogen. "Mitis" grew in a different form on these media, did not ferment starch, and occurred more often in mild attacks of diphtheria. "Intermedius" can be considered an intermediate variety of *C. diphtheriae* nearer the "gravis" end of the scale.

The danger appears to be that a doctor may conclude that an infection with "mitis" can be regarded as a "mild" infection, not demanding such instant administration of antitoxin and other proper measures. Any view of this kind might endanger the patient. McLeod<sup>1</sup> in a recent review analysed some 25,000 cases of diphtheria the bacilli from which had been typed. Though the mortality was lower in the "mitis" group—2.6% among 6,858 cases, while 11,492 "gravis" cases had a death rate of 8.1%—181 patients infected with "mitis" died. It is true that the paralytic and cardiac complications were two to three times more common in the "gravis" group than in the

<sup>7</sup> *British Medical Journal*, 1941, 2, 659.

<sup>1</sup> *Brit. Rev.*, 1942, 7, 1.

"mitis," but laryngeal obstruction occurred three to four times more often in the "mitis" group. We do not know how many of these 181 victims would have been saved by an early diagnosis of diphtheria and the instant injection of 2 or 3 c.cm. of modern "refined" or enzyme-treated antitoxin (which has a very small tendency to cause "serum reaction"), but it is safe to suggest that many would have been saved.

It is a fascinating epidemiological problem that strains behave somewhat differently in different areas—thus "intermedius" has often been the most virulent of the three types in Liverpool and several other areas. "Mitis" in the small collection of 310 American cases caused a death rate of 8.1%. M. Frobisher,<sup>2</sup> writing from Baltimore, finds the strict determination of the types so often in disaccord with their effect on the patient that he speaks of an unfortunate confusion between clinical and bacteriological terminology, and favours the application of Roman numerals to the half-dozen or more serological groups that the laboratory worker is able to make in McLeod's three groups. McLeod,<sup>1</sup> after a survey of the world literature available at the middle of 1942 and discussion of the serological subgroups within his main three groups, considers that the three groups "gravis," "intermedius," and "mitis" comprise all the cultures yet identified—except "a small percentage of strains." Whether further research in different parts of the world increases this small percentage to a larger one or not, the terms introduced by the Leeds workers are probably near enough to the truth to have come to stay. An interesting feature of the whole problem is that, though diphtheria antitoxin in use in the whole world was made almost entirely for many years from the descendants of one culture, Parke 8, generally considered to be an "intermedius" variety, the brilliant success in immediate stoppages of outbreaks of diphtheria by the injection of this antitoxin was virtually unbroken, though widely separated epidemics must have been caused by many different bacillary types. Further, it is virtually true that the nursing staff in diphtheria wards can be kept entirely free from attacks of diphtheria by immunization with prophylactic made from this same Parke 8 intermedius strain, though they must repeatedly be exposed to infection by all types when nursing.

### THE KENNY METHOD CRITICIZED

Under the title "Fact and Fancy in Poliomyelitis" there appeared in the *Journal* of July 31, 1943, a critical review of a book by Pohl and Kenny in which the latter's methods of treatment in acute poliomyelitis, and the hypothesis by which the method was sought to be rationalized, were fully discussed. The "new concept" of the disease proposed that the well-known lesions in the motor nerve cells of the ventral horns of the cord were irrelevant, and that true paralysis from destruction of nerve cells was exceptional and unimportant, but that the residual symptoms were due to shortening and wasting of inflamed muscles which had not been properly treated in the initial stage of the illness. The essential lesion of the disease is, according to this concept, an inflammatory condition of muscles leading to spasm, pain, temporary "mental alienation" of muscles, and incoordination. All this is curable by the Kenny method of hot packs and re-education exercises initiated at the earliest possible moment after diagnosis, and the permanent disabilities with which we are all so familiar are due solely to the neglect to combat the muscular inflammation by the Kenny procedures. In short, we have never treated the malady properly because we did not recognize

its true nature. It was easy to expose the fantastic nature of the new concept, and in a recent article J. A. Key<sup>1</sup> provides the necessary criticism of the method. He states that all the cases of so-called cure obtained by the Kenny method that have come under his observation have been those of patients who were never paralysed but belonged to the abortive or non-paralysed group that bulks so large in every epidemic. In claiming 80% of cures for her method Sister Kenny, he says, has omitted to point out that she includes cases of this category, if indeed she recognizes it. In addition she contrasts this figure of cures with the 12% of cures recorded by McCarroll, whose cases came under observation and were treated only because they were in fact already paralysed. Key deprecates the use of broadcast and of lay press to advertise claims of this order.

In a detailed comparison of orthodox and Sister Kenny's methods of treatment Key states that the latter tend to aggravate the illness and to disturb the patient because they involve the application of hot packs and the use of re-education exercises in the initial febrile stage of the illness; that they are wasteful of man-power and of material; that they are applied to many cases that, being of the abortive variety, do not require it; that they lead to unnecessarily prolonged immobilization of the patient on his back; that they handicap mobilization also by the neglect to use appropriate mechanical walking and other supports; that they omit the proper assessment of muscle weakness; that they tend to prolong pain and spasm and do not prevent the development of stiffness and muscle shortening. Finally, he says, patients are buoyed up by extravagant promises of cure. In no case are the results better than by the use of the methods commonly adopted.

These conclusions will tend to confirm doubts left in the minds of readers of Pohl and Kenny's book already referred to. The new concept was manifestly untenable, and it now appears that the method itself is open to objection, and claims made in respect of it have not shown the dispassionate and careful character we have the right to expect of them. It is particularly unfortunate that the direct appeal to the lay public by Press and radio, indicated by Key, should have been made. The public cannot be judges of pathological hypotheses or of therapeutic methods, and false hopes are raised by extravagant and ill-founded claims made in this way. It is not so many years ago that the scientific assessment of the value of convalescent serum in poliomyelitis was prejudiced by such publicly made claims. These claims effectively prevented the making of the necessary control observations, for public opinion in the countries concerned would not tolerate the withholding of serum, for which high claims had been made, from any proportion of cases. The only valid appeal when a method of treatment is under investigation is to expert judgment, given due time and opportunity of observation. A campaign that ignores this principle and flies to the public emotional appeal over the heads of the only proper tribunal does its cause a disservice and gives nothing to medicine.

The next session of the General Medical Council will open on Tuesday, May 23, at 2 o'clock, when the President, Sir Herbert Lightfoot Eason, will take the chair and deliver an address.

**Correction.**—The lecture on "Teaching and Practice in Preventive Medicine," by Dr. J. M. Mackintosh, noted in last week's issue, will be given on June 23—not June 2—at the London School of Hygiene and Tropical Medicine, and it is not a public lecture.

## AERIAL CONVECTION FROM SMALLPOX HOSPITALS

BY

C. KILLICK MILLARD, M.D., D.Sc.

*Ex-M.O.H., Leicester*

Forty years ago the theory of the spread of infection from smallpox hospitals to the surrounding population by means of "aerial convection" was accepted by a majority of epidemiologists and regarded as definitely established. To-day the theory has receded into the background, and many are frankly sceptical as to its validity. Thus Harries and Mitman, in their *Infectious Diseases* (second edition, just published) say, in referring to this question, "There are still some who hold the view," but it is clear that they themselves disbelieve in it. In Jameson and Parkinson's *Synopsis of Hygiene*, published in 1934, the theory is not even mentioned, though they give the Ministry of Health's regulations as to the siting of smallpox hospitals, which are based on the theory. It scarcely seems likely that this omission was an oversight: Parkes and Kenwood's *Public Health* is also against it. C. V. Chapin, formerly Superintendent Officer of Health for Providence, U.S.A., in his *Sources and Modes of Infection*, published in 1910, after discussing the question at some length sums up against the theory; and he gives the impression that this is the general view in America.

The question is by no means of merely academic interest. On the contrary, it is of considerable practical importance. Local authorities throughout the country have to make provision for the isolation of smallpox, even though it be only for odd cases which may never occur; and to comply with the Ministry of Health's regulations such hospitals have to be at least a quarter of a mile from another institution or population of 200, and at least half a mile from a population of 600. To maintain all these institutions, seldom or never used, is not an economic proposition; and to open one in a hurry, at short notice, and provide the requisite staff, is often most inconvenient. If the theory of aerial convection can really be disregarded as of no practical importance, there seems no reason why smallpox cases should not be treated in a separate ward in a general isolation hospital with better supervision and much less inconvenience.

It seems desirable, therefore, that the whole question should be reviewed by going back to the original reports upon which the theory was based; and by the courtesy of the Medical Department of the Ministry of Health I have been given access to the Ministry's Medical Library, where I have been able to refer to these reports and other relevant literature. This article is based upon what I have recently been reading.

### History of the Aerial Convection Theory

It was in the great epidemic of 1871 that the Metropolitan Asylums Board began to isolate smallpox cases in hospital; and until 1886, when cases were removed to the Hospital Ships at Long Reach, on the Thames, to the east of London, the smallpox hospitals were situated inside the Metropolis and surrounded by thickly populated areas. It was in respect of Fulham Hospital, in 1881, that W. H. Power, a medical inspector of the L.G.B., demonstrated the influence of the hospital on the prevalence of smallpox in its neighbourhood. He was able to show, and illustrate by a series of spot-maps, that following the use of this hospital for smallpox a graduated intensity of smallpox incidence occurred among the surrounding houses, the percentage of houses invaded becoming gradually less as the distance from the hospital increased. This "influence" of the hospital could be observed up to at least one mile. He satisfied himself, after careful inquiry, that this influence could not be explained by "hospital operations"—i.e., contact with the hospital staff, visits of tradesmen, movements of ambulances, and visits of patients' friends or relatives. He therefore propounded the theory of "aerial convection," or distal conveyance of infection through the atmosphere. Although this had often been suggested before, Power was the first to put the theory forward officially and attempt to justify it scientifically.

The striking facts obtained with regard to Fulham naturally led to inquiry as to whether other smallpox hospitals in London

had brought about increased prevalence of the disease in their surrounding neighbourhoods; and in the Report of the Medical Officer of the L.G.B. for 1886 there was published a section—"Statistics of Smallpox Relative to the Operation of Smallpox Hospitals in the Metropolis"—which showed unmistakably that during the period 1876-85 the hospitals receiving acute cases had been associated with an excessive prevalence of smallpox in surrounding areas. Similar evidence was forthcoming from smallpox hospitals in the Provinces. Speaking in 1886 at a special debate on this question before the Epidemiological Society, Dr. G. S. (afterwards Sir George) Buchanan said:

"We cannot get away from these facts; they are as definite as any known to epidemiology. They had already been ascertained by a multiplicity of careful and detailed observations, in many hospitals, in different epidemics, in London and the Provinces. Recent epidemics have now enabled the question to be tested afresh."

That smallpox hospitals have had a deleterious influence in disseminating the disease in surrounding areas is now admitted, so there is no need for this aspect of the case to be argued further; but it is noteworthy that with no other disease has a similar influence been established. In this respect smallpox stands alone, which proves that its infectivity is exceptional. It is as to the explanation of the influence exercised by smallpox hospitals that difference of opinion exists.

Those who disputed the theory of aerial convection argued that the increased prevalence around hospitals could be explained by human contact in connexion with the normal operations of the hospital, supplemented by irregularities due to laxity of discipline. Against this line of reasoning there was the fact that only in the rarest instances could any contact, direct or indirect, be discovered, in spite of searching inquiry; the great majority of the cases occurring in the vicinity of hospitals were untraceable except on the theory of aerial convection. This is quite contrary to the usual experience in investigating the aetiology of smallpox cases, for careful inquiry will generally elicit some human contact, direct or indirect. There was also the fact that the increased incidence did not follow the main traffic routes to and from a hospital. Moreover, it was pointed out that when hospital staff go on leave they do not visit in the immediate vicinity of a hospital, but rather make for the shopping centre and places of entertainment; also, that tradesmen are not usually appointed because they happen to reside near to the hospital, and that visitors to patients come from all parts of a town where the patients themselves reside. Lastly, even though laxity of discipline might account for occasional spread in the early days, it is to be expected that it would be tightened up after attention had been publicly drawn to the danger. Yet in the case of the Fulham Hospital the influence reported by Mr. Power in 1881 was found to be again in operation in the epidemic of 1885.

Some epidemiologists still seem to think that there is an inherent improbability in aerial convection, so it may be well to say a word about this. It may be taken for granted that the infection of smallpox, as with all infectious diseases, is particulate, and we know that finely particulate matter—carbon, cement, lava—can be carried by the air for great distances. In some manner the infection of smallpox leaves the patient's body and gets into the air of the sick-room or ward, and a susceptible person inhaling that air will readily contract the disease. Infection, then, can be carried by the air for short distances, and this may happen in the open air as well as in the sick-room. The only real question is, For how long can the infection survive exposure to the outside atmosphere? And here it is important to remember that the infection of smallpox, probably more than that of any other disease, can be carried by fomites. This fact certainly suggests that it is exceptionally resistant to desiccation and that it can survive for considerable periods outside the human body. This may explain why aerial convection has been demonstrated only in the case of smallpox. It would seem, therefore, that there is really no inherent improbability in the theory; it is just a matter of weighing the evidence.

### Smallpox in the Orsett Union

The theory of aerial convection as opposed to contact conveyance by hospital operations received striking support from

the experience of the Orsett Union, in the epidemic of 1901-2, in connexion with the Hospital Ships at Long Reach, where cases of smallpox from the Metropolis were then being treated. These hospital ships were moored in the Thames near the Kentish shore, while the Orsett Union was on the opposite or Essex side. During this epidemic the Orsett Union suffered severely, and the outbreak was the subject of a special report by Dr. G. S. Buchanan. He wrote:

"The most striking feature of the epidemic is the remarkable intensity of its incidence on the small community of Purfleet. . . . Out of 110 dwellings no less than 44 were invaded by smallpox. . . . As regards the influence of the hospital ships upon the prevalence of smallpox in Purfleet, we have to choose between aerial convection or nothing; there is here no question of infection, direct or mediate, through human intercourse or traffic."

Purfleet was the parish in the Orsett Union which was the nearest to the ships on the Essex side of the river, but all communication with the ships was from the Kentish side. Not only did it suffer by far the most heavily, but it was the first to be attacked. The next most heavily attacked was West Thurrock, which also happened to be the next nearest to the ships. No other explanation of these facts could be given, for in this case hospital operations could be ruled out. Dr. J. C. Thresh, M.O.H. for Essex, pointed out that all this had happened before, and that in the two previous epidemics since the ships had been used for smallpox Purfleet had suffered exceptionally. The distance from the ships to Purfleet was under three-quarters of a mile, but Dr. Thresh believed that the influence of the ships could be traced for a much greater distance to other parishes in the Union.

#### The Epidemiological Society Debate

In 1904 a full-dress debate on this question took place before the Epidemiological Society of London, when a paper supporting the theory of aerial convection was read by G. S. Buchanan, and many of the leading epidemiologists of the day took part in the discussion. Dr. C. B. Ker, Medical Superintendent of the Edinburgh City Hospital, who opened against the theory, said that he based his objection on his own negative experience at Edinburgh. There the smallpox hospital adjoined not only the fever hospital but the poor-houses and another institution, and there was a population of some 3,000 within the one-mile radius; yet, although for three months they had had an average of nearly 50 smallpox patients under treatment, there was no evidence of infection having spread from the hospital. He concluded that, while not denying the possibility of aerial convection, for practical purposes it might be disregarded. Dr. (afterwards Sir Arthur) Newsholme considered that the theory was not yet proved, and he waited for further confirmation. He thought that excessive prevalence round a smallpox hospital, when not due to coincidence, could be explained by personal contact; and as regards the Purfleet experience, he suggested that surreptitious visits by members of the hospital ships' staffs to the Essex shore might have taken place. (Dr. Buchanan in his reply said that the only instance of this discovered was the case of one man who had visited his sweetheart.) Analysing those who took part in the debate, we find that 12 were in favour of aerial convection and 7 against. Apparently expert opinion at that time was strongly in favour of the theory, and it is noteworthy that since then there has been no further opportunity of testing the theory, owing to the disappearance of epidemic smallpox from this country. In the presence of positive evidence, such as certainly exists from a number of different hospitals in different epidemics, negative evidence from other hospitals cannot settle the question. Innumerable instances have been recorded of failure to infect by personal contact (as where tramps in the early stages of smallpox have wandered about a town without infecting others), yet no one would suggest that this proves that smallpox is not infectious by personal contact. As regards aerial convection, we know little about the conditions necessary for the survival of the smallpox virus outside the human body, or of the meteorological conditions most favourable to this. It has been suggested that it may be related to the presence or absence of ozone, dampness, fog, etc., in the atmosphere.

To sum up, I feel that the case for aerial convection is very strong—much stronger, indeed, than many present-day

sceptics imagine. I think that if they could spare time to consult the original reports they would admit this. At the same time it might be justifiable to allow certain hospitals to try isolating smallpox in general isolation hospitals and watch the result.

In the meanwhile, the theory of aerial convection does certainly provide a solution (and here I speak from personal experience) for remarkable facts in smallpox aetiology which cannot otherwise be explained.

#### CANCER RESEARCH

Prof. H. R. Dean, chairman of Council of the Imperial Cancer Research Fund, presided over the annual meeting of the Fund, which was held at the Royal College of Surgeons of England on April 19. Viscount Halifax was re-elected president of the Fund and Sir Holburt Wariog treasurer. Mr. L. E. C. Norbury and Dr. C. H. Kellaway replace Mr. Sampson Handley and Prof. Major Greenwood on the Council as representatives respectively of the Royal College of Surgeons and the Royal Society.

In a brief account of the year's work Prof. Dean said that in cancer research progress was always slow, but during the last twenty years the rate of progress had been accelerated, and this was due partly to the fact that the observation of cancer as it occurred in human beings had been supplemented by the production of cancer experimentally in animals, but even so, the results of one experiment might need to be observed over a number of years, and every report of a research body such as their own must necessarily be of an interim character, recording investigations which might yet be long in reaching their conclusion.

#### Prostatic Cancer: Two Advances

What appeared to be the most important contribution of chemotherapy to cancer so far made was the administration of diethylstilboestrol, the synthetic oestrogenic compound originally prepared at the Middlesex Hospital, in the treatment of cancer of the prostate gland. This work had the further interest that it was an example of treating gland cancer with a chemotherapeutic substance having the essential physiological properties of a natural hormone. As soon as this method of treatment was announced, Dr. E. S. Horning, a member of the Fund's scientific staff, undertook to study the prostate gland in mice, and to attempt to induce glandular cancer by injecting a chemical carcinogen into the epithelium of the anterior lobe of the organ. In this he was successful, and six epithelial tumours were obtained out of fifty mice treated. This work had been continued by Dr. L. Dmochowski, a visiting research worker, and the chemically induced prostatic cancers had now been transplanted and were being studied.

#### Other Experimental Work

Two other research workers for the Fund, Dr. R. J. Ludford and Miss Hilda Barlow, had been investigating sarcomas arising in the stroma of transplanted breast cancers derived from inbred strains of mice, and had found that when spontaneous mammary cancers of these mice were propagated, each in mice of the strain in which the tumour arose, malignant transformation of tissue stroma was apt to occur. The sarcomas could be separated from the mammary cancers and propagated independently. An opportunity had thus been afforded for close study of these tumours *in vitro* as well as *in vivo*, and at all stages of their development. It confirmed that in some mammary cancers the malignant cell was able to induce malignancy in a neighbouring connective cell.

Another member of the Fund's scientific staff, Mr. H. G. Crabtree, had continued his search for a substance which would inhibit specific metabolic processes on the induction of cancer in mice. He had previously drawn attention to two substances—namely, the groups of compounds represented by chloroacetone and by bromo-benzene respectively, which, though chemically unrelated, were intimately concerned with cancer metabolism, and to these he had now added a third—namely, maleic acid, used as the more fat-soluble maleic anhydride, which was proving even more effective than bromo-benzene as an inhibitor of carcinogenesis when applied in an appropriate

concentration. All the three classes of substances had the common property of fixing labile sulphhydryl groups by three different types of chemical mechanism, all producing the biological effect of checking the action of chemical carcinogens. The inference was that sulphur, in an unknown way, was concerned in this type of cancer induction.

## Nova et Vetera

### HISTORY OF EPIDEMIOLOGICAL DOCTRINES

An English student of medical history reads in 1944 Dr. Charles Edward Amory Winslow's book, *The Conquest of Epidemic Disease*\* with a pleasure perhaps faintly tinged by envy and regret. He may not care much for the title; epidemic disease has not been conquered and the phrase gives no hint of the content of the work. But he will envy the admirably clear style of the writer and the way the book has been produced.

Dr. Winslow set himself the pleasant if laborious task of writing a history of opinion, choosing the authors whom he regarded as of primary importance and, so far as possible, letting them speak for themselves. This method easily degenerates into either a mere anthology with more or less relevant footnotes or into a catalogue of names. Dr. Winslow has avoided both mistakes, and, certainly so far as writers of the last 200 years are concerned, has fully succeeded. His study of Pettenkofer deserves particular praise. It is not easy to write sympathetically on a champion of a lost cause when one feels that, on the whole, the cause was deservedly lost; but Dr. Winslow has done so. One regrets that another champion of lost causes, who, like Pettenkofer, said many true and some profound things, Charles Creighton, is not commemorated in these pages. A special and rare merit of Dr. Winslow's exposition is its freedom from the vice of neocentricity—viz., the assumption that because a writer of the remote past taught something which resembles what we now believe to be true, *therefore* he must have been an exceptionally good reasoner. He may easily, of course, have been a very bad reasoner who guessed happily.

### Contagion or Infection in Ancient Thought

Much of the first half of the book is devoted to an appraisal of the parts played by the concepts of contagion, or infection, and of atmospheric katastases, or constitutions, in the epidemiology of the Greek, Hellenistic, and mediaeval physicians. As Dr. Winslow remarks, few, probably no modern, physicians have mastered the whole of even Galen's writings; each of us must form a judgment on incomplete data. The reviewer certainly does not claim a wider knowledge than that of Dr. Winslow and his collaborator, Prof. Hendrickson, of the sources; but, having been an interested reader of Galen for many years, may attempt to supplement Dr. Winslow's discussion by epitomizing an argument published more than twenty years ago (*Proc. roy. Soc. Med.*, 1921, 14, Sect. History of Med., p. 3).

Contagion or infection in ancient thought has two origins: from the pre-scientific idea of sympathetic magic and as a scientific corollary of the hypothesis of atmospheric change. The magical idea was wholly rejected by the Greek thinkers, but in many, perhaps a majority, of the passages in Latin poets and historians where the word "contagium" occurs that idea lurks. The notion of an atmospheric origin of disease, of a miasma spreading, is akin to that of transmitted vibrations, and at once suggests the analogy of tuning-forks picking up a pure note and transmitting it. Suppose the forks aligned, then the nearest to the original source of sound will first respond, and there is "infection" from one to another. I do not think that in any of the passages cited by Dr. Winslow, or in others which might be cited, Galen's idea of infection went beyond this. One inconsistency (see Dr. Winslow's book, p. 73, footnote) is explained by Prof. Hendrickson as due to a corrupt reading. There is another (see Greenwood, *op. cit.*, p. 7) which does seem to postulate seeds of pestilence in

Fracastor's sense; but the Greek text of the work has not survived. If this is a just analogy, the Greek scientific theory of contagion is merely of conduction; the tuning-forks originate nothing; so to Galen contagion was of secondary importance, he concentrated on the atmospheric katastases and the human crises. To Fracastor belongs the credit of imagining a fresh liberation of energy in each member of the series. Whether he conceived the process as chemical or biological is not, perhaps, a very important question. Had this hypothesis presented itself to Galen, the whole course of medical history would have been different.

### Influence of Galen

Dr. Winslow remarks that "it is a fundamental error to consider Galen as merely a compiler." One may be permitted to doubt whether a single reader of *any* tract by Galen (after all one of Galen's major works is available in the Loeb series) could have made that mistake. But no doubt Galen, like Malthus, is usually judged by people who have never read him. Dr. Winslow writes:

"It is perhaps significant of the difference between the Greek and the Roman mind that Hippocrates is intrigued by problems of causation while Galen—Roman in environment if Greek by race—is almost exclusively preoccupied by the immediate practical problems of diagnosis and treatment. One is essentially a philosopher, the other an experimenter and clinician."

This judgment would have made Galen—two of whose most famous minor works are developments of the argument that a good physician must be a philosopher—very angry and, so far as epidemiology is concerned, is disputable. The most famous Hippocratic writings on epidemiology described observed facts, but Galen, as Littré said, although his opportunities of observing group-disease were far wider than Hippocrates', has left no detailed account of observations. One might easily support a conclusion the precise opposite of Dr. Winslow's and hold that the intellectual weakness of Galen—typical of the Hellenistic Greeks—was over-confidence in dialectic. Perhaps, however, Dr. Winslow had in mind *De Sanitate tuenda*, which might pass as a good practical work on personal hygiene, if the only human beings worth teaching were Roman plutocrats. Dr. Winslow does not give much space to Galen's Semitic followers. As the voluminous Avicenna is only available (except to those who can read Arabic) in dog Latin, this was inevitable, and we may fairly suppose that had an Arabic scholar found pearls of epidemiological wisdom in this large mass of oysters, they would have been displayed by now. One wonders whether Chaucer's "Doctor of Physik" could have read Avicenna all through!

Coming to modern times, Dr. Winslow's account of Kircher on contagium animatum may be instructive to others beside the reviewer, although it may not convince them that Kircher was quite first-rate. The chapter on the enigma of yellow fever tells us a good deal about Rush and Webster which will be new to English and, possibly, American readers. The remaining chapters cover ground which is familiar, although—as noted with respect to Pettenkofer—Dr. Winslow has judiciously used sources not tapped by most textbook writers.

### Pioneers of Statistical Epidemiology

The reviewer—mindful of the cobbler's belief in leather—regrets that Farr plays but a small part and John Graunt no part at all in Dr. Winslow's drama, because he thinks that Graunt's contribution to epidemiology was immensely greater than Sydenham's. It was the London shopkeeper not the learned physician who really returned to Hippocrates as an epidemiologist, displaying essential facts with the help of a method, an organon, which the father of epidemiology might have envied. At least we can thank a countryman of Dr. Winslow for the only modern reprint of Graunt's book. Perhaps, encouraged by the success this book deserves, Dr. Winslow will tell the story of other forgotten pioneers of statistical epidemiology on both sides of the Atlantic. His book is escapist literature in the best sense of that adjective. It takes us out of ourselves and strengthens belief in intellectual progress through epochs almost as gloomy as that in which our own lot has been cast.

# INJECTION TREATMENT OF VARICOSE VEINS

'Ethamolin' as a sclerosing agent has the outstanding merit that, while it produces the firmest and most adherent thrombus, accidental leakage of the solution into the tissues around the vein will not cause sloughing.

Pain following the injection is very infrequent, and there is considerably

less tendency to any reopening of the vein.

'Ethamolin' is a stable chemical compound of consistent potency ensuring uniform results. It is powerfully bactericidal, and thus it reduces to a minimum any risk of introduced infection from the injection.

## ETHAMOLIN

BRAND OF ETHANOLAMINE OLEATE  
2 cc. ampoules in boxes of 6 and 100. Bottles 15 cc. and 30 cc.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRON 3434.

## ERGOMETRINE B.D.H.

*The Rapidly-acting Alkaloid of Ergot*

Ergometrine has been shown to possess an oxytocic action equal to and as rapid in onset as that of posterior pituitary gland extract. It possesses also the advantages of not affecting either the vascular or autonomic nervous systems.

The use of ergometrine, either before or after delivery of the placenta, for the control of post-partum hæmorrhage, is to be recommended; it may be used advantageously also for the treatment of those cases in which the lochial discharge is partly retained in the uterus. Ergometrine B.D.H. is issued in solutions in ampoules for intramuscular or for intravenous injections, in hypodermic tablets and in tablets for oral administration.

*Details of dosage and other relevant information will be gladly supplied on request.*

# 'Sudermo' BRAND MESULPHEN

## in the treatment of parasitic skin disorders

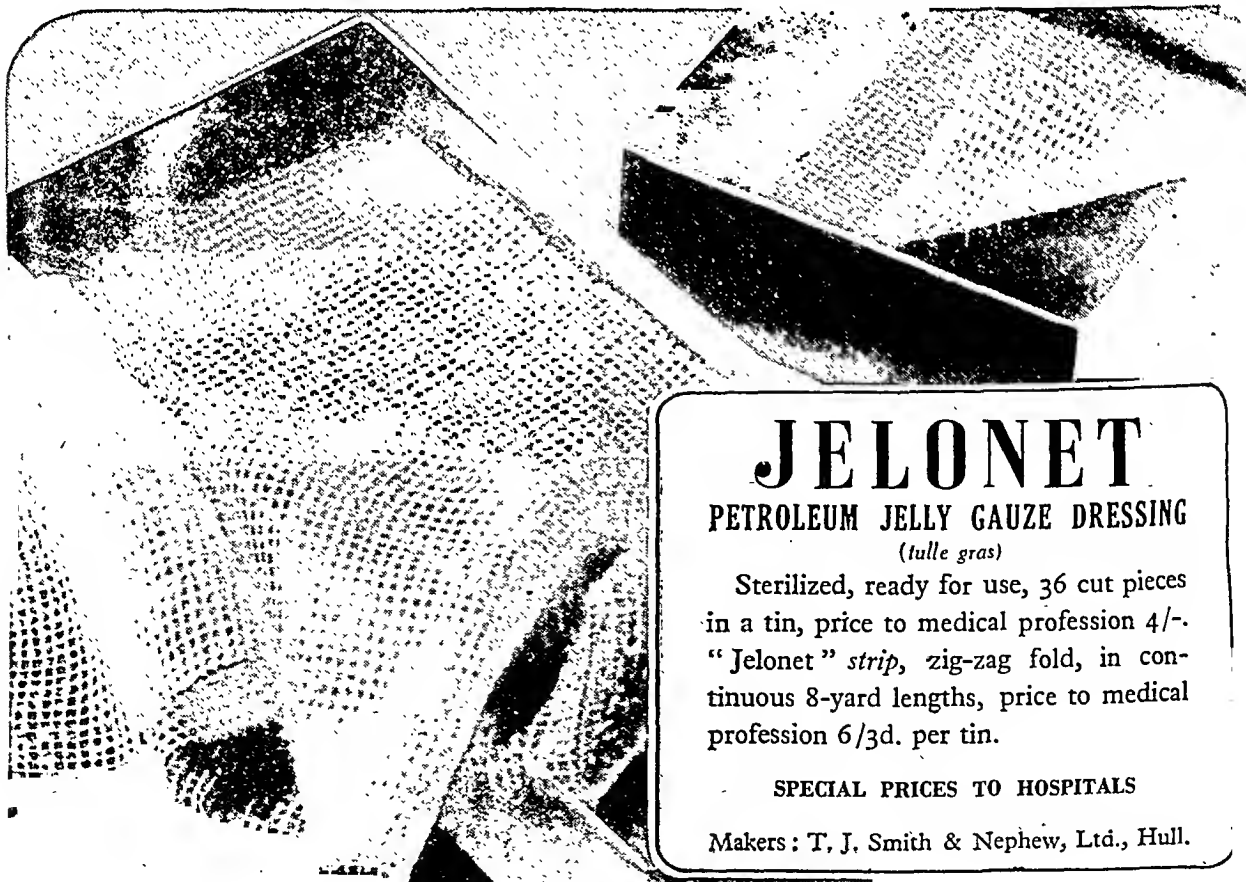

Applied externally, 'Sudermo' exerts a marked parasiticial action, due not only to the contained sulphur but also to the hydrocarbon complex in which it is combined. Some indications include scabies; scabious eczema; seborrhœic dermatoses; pruritus; pediculosis pubis, corporis and capitis; acne. 'Sudermo' brand Mesulphen is a homogeneous, oily liquid containing approximately 25 per cent of organically-combined sulphur. It is readily

absorbed by the skin without irritation or damage to mucous membranes.

'SUDERMO' brand Mesulphen, bottles of 100 c.c., 4/6 (Purchase Tax 7d. extra), bottles of 1000 c.c., 33/0 (Purchase Tax 4/1½ extra). 'SUDERMO' brand Ointment containing 25 per cent Mesulphen and 25 per cent sulphur, glass jars of 20 grâmmes, 1/6 (Purchase Tax 2½d. extra). Subject to medical discount.

## JELONET

### PETROLEUM JELLY GAUZE DRESSING

(*tulle gras*)

Sterilized, ready for use, 36 cut pieces in a tin, price to medical profession 4/-. "Jelonet" strip, zig-zag fold, in continuous 8-yard lengths, price to medical profession 6/3d. per tin.

**SPECIAL PRICES TO HOSPITALS**

Makers: T. J. Smith & Nephew, Ltd., Hull.

## HISTORY OF PHARMACY

*Historical Survey of Pharmacy in Great Britain.* By Carl Schmiedler, of C. R. Harker, Starg, and Morgan, Ltd., Devon Wharf, Emmot Street, London, E.1. (Pp. 91.)

Next year will be the 600th anniversary of the opening in London of the first apothecary's shop of which there is historical record, and this little book therefore appears at an appropriate time. The author takes pains to show, quite rightly, that the choice and manufacture of drugs was an art which had developed through many centuries before 1345. Much is known of pharmacy in ancient civilizations, but in this country drug selling is first mentioned in the Pipe Rolls for 1180; in Italy there is evidence that such shops existed in 1140. In these early days the choice of drugs was bound up with astrology and superstition; the alchemical era was the last stage before pharmacy passed to its close partnership with the embryonic true sciences. The book traces the development of the trade through its association with the "Pepperers" and the East, and through its stormy controversies with the physicians after its emancipation as the Apothecaries Company in 1617. Although the *London Pharmacopoeia* was published in 1618, it was not until 1721 that ancient superstition was eliminated from its pages, and the first *British Pharmacopoeia* did not appear until 1858.

The history of pharmacy is a vast subject, and the author has had to choose his line of approach. He deals little with the history of individual drugs, and thus deprives himself of the opportunity of mentioning incidents such as that of the Liocolnshire grazier who in the space of twenty-one years swallowed 40,000 bottles of mixture and 226,934 pills—and finally had to be sued for the bill! There are a few errors: Newton was never an apprentice, but as a schoolboy he lodged with an apothecary named Clark. For the uninitiated a sharper distinction might have been drawn throughout between the apothecary and the druggist. But these are minor matters. The author set out to give a history of pharmacy as a trade in this country, and from this aspect and within his allotted space he has carried out his task sincerely and with considerable success.

## Reports of Societies

## GASTRO-ENTERITIS IN INFANTS

At a meeting of the Fever Group of the Society of Medical Officers of Health on March 31, with Dr. ANDREW TOPPING in the chair, a discussion on infantile gastro-enteritis was opened by Dr. REGINALD LIGHTWOOD.

Gastro-enteritis, he said, was not a disease *sui generis*, but could arise from enteral or parenteral causes. The latter had been stressed in recent years, but it was often difficult to decide whether a parenteral infection caused the enteritis or was secondary to it. Gastro-enteritis was one of the oldest scourges of infants in hospital, and in open-ward conditions high death rates had occurred, particularly so in medical wards, partly because the infection was always being reintroduced and partly because cases arising in the surgical wards were transferred to the medical side. The isolation unit for enteritis cases opened in the Hospital for Sick Children, Great Ormond Street, in 1938 had proved of inestimable value. Although certain facts about the aetiology of zymotic diarrhoea were well established (its virtual disappearance in countries where mothercraft was well taught and practised and its rarity in breast-fed infants) much was still to be learned. Some of the problems were: bacterial cause; the mode of infection in primary cases; the mode of spread; the need for separate cubicles for each case; the necessity for staff to wear masks; and the advisability of nursing parenteral cases near enteral cases. Dr. Lightwood had seen no response to sulphaguanidine, but sulphadiazine and sulphamezathine appeared equally effective for any parenteral infections present. He favoured 5% glucose in half strength Hartmann's solution for intravenous fluid therapy, and recent experience with plasma or serum (diluted with equal parts of the above solution) had given encouraging responses after the initial dehydration had been combated—i.e., after six to

twelve hours. Mastoidectomy had been performed in 9 cases during the last nine months, 5 being fatal, due, he thought, to the debilitated and toxic condition of the child at the time. The operation could be done under local anaesthesia without much apparent disturbance to the general condition of the infant.

Dr. L. J. M. LAURENT said that infantile diarrhoeas were usually classified in three groups: (1) non-infective (mostly dietetic in origin); (2) symptomatic (due to a parenteral infection); (3) infectious, of primary gastro-intestinal origin. But in practice it was often impossible to assign an individual case to its proper group without a week's observation. The mild diarrhoea occasionally seen in the measles or whooping-cough wards at first sight seemed to be of dietetic origin; but the condition often spread in series of cases, and he suspected that the majority were infective. Under "symptomatic diarrhoeas" due to a parenteral infection at all ages should be included the diarrhoeas of puerperal septicaemia, early typhoid, cerebro-spinal fever, toxic scarlet fever, and severe otitis media and broncho-pneumonia in infants. With suitable treatment improvement was usually rapid, though symptoms like dehydration often needed correction. The infectious diarrhoeas of primary gastro-intestinal origin fell naturally into two groups: (a) those of known aetiology—namely, the dysenteries, the enterica, and the salmonellas; (b) those of unknown aetiology, which were a baffling problem. The wide differences in case fatality for gastro-enteritis given by different hospitals (7% up to 53%) could not be explained by age, season, and lines of treatment. He thought at least two diseases were concerned, which he designated Type A and Type B.

In Type A an incubation period, usually of three days, was followed by sudden onset with pyrexia and vomiting, some cases not having diarrhoea for 24 hours. From the start rate of breathing was high and there was a short cough. Many patients were admitted to general hospitals as cases of bronchitis and were later transferred to the fever hospital when the diarrhoea appeared. The stools were watery, bright green or orange in colour, and had a musty, oot faecal, odour which some nurses thought characteristic. Dehydration was early and profound, and toxæmia was present. Vomiting was intractable and preceded by a troublesome short cough. On the fifth or sixth day, rarely before, the temperature went higher, and with this there was unmistakable evidence of otitis media or bronchopneumonia, or of both. Death occurred in 40 to 50% of the cases and was preceded by coffee-ground vomit, hyperpyrexia, and often convulsions. Necropsy showed fatty degeneration of the liver in all, patchy congestion of the intestinal mucosa, and a few pinpoint ulcers. Pus in the middle ear was common (23 out of 32) and also bronchopneumonia (13 out of 32). He considered the otitis media and the bronchopneumonia to be secondary infections and not causes of the diarrhoea and vomiting. He had tried paracentesis years ago, but all his cases had been ultimately fatal and had showed no improvement after the operation. *H. influenzae* or pneumococci had been found on plating straight from the paracentesis knife at the bedside. Type A behaved like an acute specific infection which affected both the respiratory and the alimentary tracts, giving rise to a fatal toxæmia (or septicaemia) with frequent secondary infection of the middle ear and lungs. Clinically its spread resembled that of a virus droplet infection.

Type B was a much milder disease with an incubation period of 8 to 10 days. The onset was more gradual, with diarrhoea, vomiting, and pyrexia. Stools were more often relaxed than watery. Dehydration was in proportion to the fluid lost, and if corrected did not tend to recur. The cases were often not admitted to hospital for a whole week. There was no otitis or bronchopneumonia as early as the fifth or sixth day; the mortality in hospital cases was less than 10%. The disease behaved like a primary "enteral" infection, and it was probably this type which could be safely nursed in a "barrier" ward. The stools showed a variety of organisms of doubtful pathogenicity, but dysentery organisms were not found.

Faced with different types of infantile gastro-enteritis of different aetiologies and methods of spread the medical officer of a fever hospital had no choice but to isolate every case in a separate room. The barrier ward had become obsolete in the treatment of gastro-enteritis. In addition, a sufficient number of well-trained nurses was needed, the ratio of nurses to patients being higher than in any other ward.

Mr. E. F. GALE said that a group of workers at Cambridge had found large numbers of  $\beta$  haemolytic Group D streptococci as a "feature" of the stools in certain outbreaks of neonatal diarrhoea. These organisms had (1) an unusually

high tyrosine decarboxylase activity, and (2) the power to establish themselves in the faecal flora of the infant rat or man, properties not possessed by normal enterococci. Feeding these organisms to infant rats resulted in a fatal diarrhoea which was most marked when the diet was such as to render the intestinal medium optimal for the action of tyrosine decarboxylase; and the syndrome could be imitated by feeding tyramine itself. Older rats were not susceptible to the action of either the organisms or the amine. Estimations of the tyramine oxidase activity of fresh post-mortem material from infants showed that this activity was deficient at birth in the kidney, liver, and duodenum, but was fully developed by the end of the third month.

Dr. R. SWYER said the diagnostic error among enteritis admissions was high. Mastoiditis could arise as a late complication, but some of these cases were due to hospital infections: this view was supported by finding haemolytic streptococci in a high proportion. Dr. H. S. BANKS said that before the war the paracolony group of organisms appeared to have some place in aetiology. He felt that experiments on young animals (up to three weeks of age) were indicated. Dr. T. E. D. BEAVAN argued strongly for *ad hoc* gastro-enteritis units in children's hospitals. One of the problems of the disease was the comparative immunity of children from 12 months to 2 years and the absolute immunity thereafter. Infants with minor ailments, particularly skin diseases, should not be admitted to hospital because of the high risk of enteritis. He agreed that in the presumed infective group of unknown aetiology there were two distinct types. The odour of a severe case could best be described as spermiatic. Dr. JANET GIMSON, while stressing the need for parenteral fluid therapy, said that the intravenous route in infants was often difficult for inexperienced medical officers. She favoured bone-marrow transfusions because they were simpler to institute and could be maintained at a constant rate more easily than intravenous drips. She demonstrated a short needle with a strut-supported adaptor suitable for marrow transfusions in infants as it was not easily displaced. Dr. J. BRAY wondered if Mr. Gale had done animal-feeding experiments with amines, and pointed out that a number of organisms which were normally present were greatly increased in the presence of enteritis. In reply, Mr. GALE said that young rats (up to ten days) did develop diarrhoea when fed on tyramine. He had never met a coliform organism which produced an amine in significant quantity.

### MUSCULAR FACTORS IN FOOT FAULTS

At a meeting of the Manchester Medical Society on April 12 Mr. W. SAYLE CREER gave a lecture, which was illustrated with a cinematograph film in colour, on some foot faults related to form and function. He said that many patients complained of aching in their legs, and while some of them had foot deformities others had no obvious defect to explain the symptoms. The aching was due to muscle fatigue, which was caused by muscle overwork, and the reason for this overwork was as follows. In the normal foot unit, which meant all the tarsal bones below the astragalus, or talus, the inherent strength and shape was such that the foot was in stable equilibrium with the ground. A very common defect was an incompetent first metatarsal. This phrase meant a failure of the supporting action of the first metatarsal due to a hypermobile first metatarsal and internal cuneiform, a permanently elevated metatarsal, or a short first metatarsal. As in the case of a three-legged stool with a defective leg, the foot fell over to the inner side; Americans called the condition "pronation." The joint at which the movement took place was between the astragalus and foot unit, and in order to balance the foot the patient had to use the muscles excessively. This pronation, which was not by any means the same thing as the rare flat-foot, was the common deformity found in children and in quite a number of adults.

Other causes of muscular fatigue were factors which altered the relative tonus of opposing groups. Any painful condition of the foot—such as a corn, a wart, a callosity, or projecting nail in the shoe, or shoes which were too tight—would, by its reflex effect, diminish the tone of one group in an effort to prevent pain, and consequently increase the

tonus of the opposing group. This led to incoordination and symptoms of muscle strain. There were many factors outside the foot—such as tightness of the tendo Achillis, "squinting" knees or internal rotation deformity of the femora, tight hamstrings, excessive lordosis with its associated flexion of the hip-joint—which affected the work that various groups of muscles had to perform.

In examining the foot, small deviations from the normal had to be looked for, for the foot was a small object and deformities were very often anything but gross and obvious. In the majority of cases it was not necessary to carry out elaborate surgical procedures; the patient could be made comfortable by suitably altered footwear and the right kind of physiotherapy. The commonest type of surgical alteration to footwear was wedging the inner border of the heel and the outer border of the sole. The older method of wedging the inner border of the sole was not mechanically and physiologically sound and not so effective. The surgeon must take great care to impress upon the patient the necessity for keeping the shoes in good repair, for badly wedged or worn shoes "wobbled" and gave rise to additional muscle fatigue so that the symptoms were not relieved.

The annual congress of the Ophthalmological Society of the United Kingdom was held in London at the R.S.M. on March 31 and April 1. Among the visitors were ophthalmic surgeons of the American Armed Forces. The president, Dr. H. M. TRAQUAIR, after welcoming members and visitors, gave his presidential address on "The Nerve-fibre Bundle Defect." It was a valuable and enjoyable congress, and many of the papers gave rise to interested discussion and comment. All the proceedings, together with a report of the joint clinical meeting, will appear in the *Transactions of the Ophthalmological Society of the United Kingdom for 1944*.

The Whipps Cross Hospital Medical Society held its first public meeting on April 14 when Mr. D. G. Ardley gave a lecture on the chemotherapy of bacterial infections. There was a good attendance of local practitioners. The next meeting, which will be clinical, will take place at the hospital on Friday, May 12, at 8.15 p.m. Practitioners who wish to show cases should notify the honorary secretary of their intention at least 14 days beforehand.

## Medico-Legal

### CONTINUOUS CARE AND TREATMENT

Abundance of caution was probably responsible for most of the defects of "Herbert's Act"—the Matrimonial Causes Act, 1937. Among other grounds the Act allows a party to a marriage to be granted a decree of divorce on proof that the other party is incurably of unsound mind and has been continuously under care and treatment for at least five years immediately before the date of the petition. The definition of "under care and treatment" has already caused difficulty, and recently has been shown to conflict seriously with the best-accepted treatment of persons of unsound mind. The usual form of care and treatment under the Act is detention in pursuance of any order or inquisition under the Lunacy and Mental Treatment Acts. As the care and treatment must be continuous, if the continuity of the detention has been broken in any way the petitioner cannot have his/her divorce. In *Shipman v. Shipman* (1939) the wife had been sent out every year for a long period between Christmas and the spring to live with her sister; the President held that absence on trial for prolonged and indefinite periods must be on the wrong side of any reasonably drawn line between continuous and interrupted detention. In *Green v. Green* (1939) the husband was sent for a fortnight to a house belonging to the Mental After-Care Association; he was under the charge of the association's officers as agents for the local authority maintaining the hospital from which he came. The President did not think the detention was interrupted. The most recent case,

however, *Safford v. Safford* (1944)<sup>1</sup> turned on the question whether release on trial interrupts the detention or not. The husband was sent out twice in the summer of 1942—for fifteen days and forty-four days—and between the two periods he was back in hospital for a week. The orders were made by visitors on the advice of the medical officer, according to the Lunacy Act. On behalf of the Official Solicitor it was indicated that the Board of Control would greatly welcome in the interests of patients a decision which would, without incurring the risk of defeating the inchoate rights of petitioning spouses, encourage the use of release on trial, which medical superintendents regard as very beneficial in favourable cases, and as tending at least to alleviate the tedium of detention. Counsel on both sides invited the President to hold that the detention was continuous, but Lord Merriman regretfully decided that he could not do so. None of the relevant Acts defines the word "detained," and he felt bound to assume that if Parliament had intended the mere existence in force of a reception order to be sufficient, it would have said so. Except for daytime absences and the leave of absence for three nights or four days which a superintendent may grant under the regulations, which may be disregarded under the *de minimis* principle, there must be something which can be described as continuous detention in the mental institution itself, or something that may fairly be regarded as its equivalent. He could not bring himself to hold that absence on trial for substantial periods satisfies those requirements.

On the wording of the Act it is difficult to imagine how the President could have held otherwise. In the Scottish Act, which was passed a year later, the position is different, for that Act expressly provides that a person is "under care and treatment" while an order for his detention is in force, and when he is absent from the mental hospital the order remains in force, and detention therefore persists, for 28 days. Hence, if the patient's leave of absence is kept within that period, no question arises. Of the many amendments which the English Act requires, this seems to be the most urgent.

#### MENTAL HEALTH LEGISLATION IN SOUTH AFRICA

During the current sessions of the Union of South Africa House of Assembly legislative changes of a revolutionary kind have been made in the Mental Disorders Act of 1916, which is now amended so that the superintendent of a mental institution can no longer be compelled to retain anybody brought there at the request of any policeman. The amendments also empower judges and magistrates to commit accused persons suspected of suffering from mental disorder directly to a mental institution for observation, instead of ordering them to be held in a prison to await the Governor-General's decision. Provision is also made for the admission, for a period not exceeding twelve months, of persons suffering from apparently curable mental disablement as voluntary patients, the cardinal object being that no court order of certification is necessary. The commissioner of the institution has the power to discharge such patients at his discretion, and either the patient or next of kin has the right to apply for immediate release on conditions such as prevail in this country.

In the debate the Minister of Welfare and Demobilization, Mr. H. G. Lawrence, refused to accept an amendment absolving relatives or guardians of mental patients from paying for their maintenance. The Minister said that the Government had difficulty in accommodating patients, the present shortage being about 400 beds for Europeans and 2,500 for non-Europeans.

<sup>1</sup> *Times*, March 14

The National Union of Students (3, King's Parade, Cambridge), the representative body of students in 103 universities, university colleges, technical and training colleges in England and Wales, is at present working on student health problems in co-operation with the Scottish National Union of Students, the British Medical Students' Association, and the British Dental Students' Association. It has been concerned with this problem for some time, its activities having included the publication of a report on student health in 1937, and the encouragement of a scheme to establish an international student sanatorium. The war made impossible the immediate implementation of long-term proposals. Therefore an interim programme is being put forward which aims to keep students fit enough to meet their present responsibilities and to use fully and improve existing services in such a manner as to pave the way for a more thorough reconstruction after the war.

## Correspondence

### Publication of Anaesthetic Misadventures

SIR,—Dr. John Elam has campaigned persistently for safer anaesthesia. His latest suggestion on page 263 of your issue of Feb. 19 is one of the brightest ideas I have yet heard of for reducing the incidence of anaesthetic misadventures, major and minor. If put into practice it would indeed be effective, but in its present form it pre-supposes exceptional honesty on the part of the anaesthetist, and a considerable increase in the size of your *Journal* if it is to be the medium of confession. Before making a proposal as to how Elam's suggestion might be modified, I give my own full list of misadventures, three in all, in the belief that published evidence of this nature, if accumulated, would be of value to younger anaesthetists. I exclude a case of amputation for gangrene in an elderly woman already unconscious and moribund when brought to operation as a last desperate resort.

1. Overdose of anaesthetic. Many years ago an adult man died during a minor operation. At necropsy the sympathetic pathologist stressed a fatty heart and liver. At the inquest I was even commended on how I had dealt with the situation. Only I knew that that patient had died from my "pushing" the anaesthetic to subdue the patient's reflexes quickly. This death was due to bad anaesthesia, and yet is probably listed for statistical purposes as "fatty degeneration of the heart."

2. Mental deterioration following nitrous oxide. Anaesthesia was induced and maintained with nitrous oxide, but the operation did not commence for almost an hour owing to the surgeon's encountering unexpected difficulties with the previous case. On recovery the patient was restless, irritable, and irrational, as described by de Courville in his book *The Untoward Effects of Nitrous Oxide*. The patient died on the fourth day from pulmonary collapse. Necropsy was refused. I have no doubt that the sequence of events was attributable to prolonged anoxia due to a misuse of nitrous oxide.

3. Amputation of forearm resulting from pentothal injected inadvertently into an artery. This case was published in the *Lancet* of Nov. 6, 1943, page 571.

The pages of the medical journals testify that anaesthetists, like other mortals, rush into print more readily with their successes than with their tragedies—yet it is from the latter that more can be learnt. Anaesthetic misadventures are not rare. The accidents I have heard of recently varied considerably in character. One can well imagine the mortification of giving pentothal intra-arterially on two different occasions, each followed by amputation; the paralysing effect of injecting the wrong drug intrathecally; the tragedy of leaving the anaesthetized patient unattended for a short period to find him dead on return; of having been responsible for an explosion through ignorance of elementary physical facts; of giving chloroform under the impression that the bottle contained ether; of giving a lethal overdose of pentothal, or of local anaesthetic drugs such as cocaine and amethocaine. The cause of tragedies such as these is obvious; others are not so overt. Death on the table is a clinical problem, and in the great majority of cases the anaesthetist is the only one who can give a clue as to what went wrong; if he is frank enough to give a detailed anaesthetic history of the sequence of events prior to death his story will be far more illuminating than the most searching necropsy.

A striking fact is that anaesthetists seldom make the same mistake twice. Who has heard, for example, of the anaesthetist who has had two deaths from so-called status lymphaticus? He may make many mistakes once. This is because he has perforce to learn in the hard school of his own experience, since the misfortunes of others are not readily available to him. This can be remedied. The publication of anaesthetic misadventures in a form in which the victims can be identified by the lay public is obviously undesirable. I think, however, they could be collected and published in book form from time to time. To avoid social or legal repercussions it might be desirable to confer anonymity on the anaesthetist. The Association of Anaesthetists is now a large and powerful body. A Misadventure Subcommittee might be formed to which fellows and members could bind themselves to notify their misadventures. There would soon be available valuable

reference books of what not to do. Alternatively, an investigation on these lines might be undertaken by some scientific or philanthropic body with adequate funds at its disposal. Such an investigation would pay a good dividend in terms of human life.—I am, etc.,

Oxford.

R. R. MACINTOSH.

### The Hazard of Anaesthesia

SIR,—Much has been written recently in your columns concerning risks attached to the various methods of anaesthesia; in fact, it is rare to pick up a *Journal* without finding an illustration of some new piece of apparatus which is claimed to be of value to the anaesthetist. This seems to me to be making a simple subject into a complicated art, and no wonder that the average R.M.O. cannot be expected to administer anaesthetics with skill when he is called upon to use this massive armamentarium.

I have been giving anaesthetics in different hospitals since 1921, and have tried all the various new agents, such as cyclopropane, spinals, CO<sub>2</sub> absorber, etc., and at last have come back to where I started—open ether, allowing myself plenty of time for the patient's respiratory tract to get used to the irritation of ether vapour, about 8 minutes. The average R.M.O. will have to learn to give anaesthetics himself, as there will not be enough anaesthetists to go round when the second front opens. In fact, under Service conditions one often has to rely upon the assistance of a sensible sister or nurse.

I maintain that open ether given slowly, and if the anaesthetist refuses to be hurried by the surgeon, is as safe as anything can be in medicine. Perhaps there is only one exception, and that is in thoracic surgery, where movement of the lungs has to be controlled; but as most thoracic surgery is best left to specialized units a skilled anaesthetist in this work will be available. To sum up, care, calmness, a good airway, and open ether represent the art of anaesthesia to-day.—I am, etc.,

Rebington, Wirral.

J. M. H. HANNAN.

### What is Psychiatry?

SIR,—In view of the considerable amount of painstaking microscopic research which has been devoted, in many parts of the world, to the study of brain cortical cells in normal and abnormal mental conditions, it is a little disconcerting to find so influential an authority as the Director of the Medical Services Division of the Rockefeller Foundation committing himself to the statement, for which he produces no evidence, that there remains a much more difficult group of (psychiatric) diseases in which *no structural or chemical variation* is known to accompany in characteristic fashion the all-too-obvious symptoms of social, moral, and intellectual inadequacy, (April 22, p. 551).

In the works of Shaw Bolton, G. A. Watson, Bournville, Hammarberg, Sachs, von Economo, Vint, R. M. Norman, and many others, including even my own *Cerebral Atlas*, there is much evidence to refute Dr. Alan Gregg's hypothesis; but perhaps, as much of this is derived from the mental defective, Dr. Gregg wishes it to be inferred that the brain cells of the psychoneurotics are immune from the structural and pathological abnormalities of the lesser breeds of men. Some of the surplus wealth of the Rockefeller Foundation might perhaps be devoted to the elucidation of the truth.—I am, etc.,

Ormskirk, Lancs.

RICHARD J. A. BERRY.

### Ophthalmic Surgeon and Optician

SIR,—The article in the *Journal* of April 22 (p. 560) by Mr. Spencer Walker on the future of ophthalmic work makes me, as one of the members of the Ophthalmic Group Committee, send you some reply. I think I may say that this committee has been for many months past carefully considering the future of medical eye work: work involving ophthalmic medical practitioners, nurses, optician-refractionists, and dispensing opticians; workers of such order as will inevitably be necessary if the new National Health Service establishes regional health centres for certain medical attention, of which, without doubt, eye work would be one form of service. Such

centres may be attached to hospitals preferably. The Ophthalmic Group Committee has drawn up an excellent draft of a scheme for the future. That draft is before all members now. Such a scheme will doubtless involve the National Eye Service as at present working under the direction of the National Ophthalmic Treatment Board, of which I am chairman.

Personally, I think that the work of the National Eye Service has been uncommonly successful and useful. The B.M.A. and the Dispensing Opticians Guild started this service at the request of the special committee appointed by Parliament to consider the claim of the sight-testing opticians presented to Parliament in a Bill laid before the House of Commons. That special committee emphasized the importance of trained medical eye experts, and every item of experience I have had as chairman of this Board has confirmed this.

The work of our National Eye Service has been especially useful when run in clinics. The value of the service is perhaps best shown by the way it filled a serious gap in the Government medical provisions at the outset of this war. The service was of particular use in that catastrophic time. When war threatened an officer of the War Office asked if the Army might make use of the N.O.T.B. organization for the care of the "file" of the Army. On my own responsibility, as chairman of the Board, I replied it could. The work the N.O.T.B. has done for the Army and Air Force since then, and particularly in the early years, has been immense. I wish I could display the figures that I have here before me, with the numbers of the soldiers attended by the N.O.T.B.; I think that would be a surprise to colleagues. But let it be noted that the facility given by the N.O.T.B. organization has justified itself in one respect: the number of recruits referred for eye examination, I have been informed, has exceeded considerably the number referred for all other medical and surgical defects! That fact, shown in the early years of the war, indicates how important are satisfactory arrangements for eye examination, eye care, and eye treatment. There is no doubt that some national and regional eye service for all who do not wish to make their own arrangements will be of high value to our fellow citizens.—I am, etc.,

Crockham Hill.

N. BISHOP HARMAN.

SIR,—The White Paper states that the design of the National Health Service shall be comprehensive from the outset, and be fulfilled as fast as resources and man-power allow. Some temporary limitations of the full service in ophthalmology are expected to be inevitable. During the period of negotiation ahead of us it is the duty of all ophthalmologists to take an active part and endeavour by constructive criticism to find a solution of the problem of laying the foundation-stone of a sound and comprehensive ophthalmic service for the whole community.

In your issue of April 22 Mr. Spencer Walker of Hove submits a solution which, as he says, is similar to my plan, which I have been urging on the profession for a considerable time. He came to his conclusions independently of me, and I have known for some while that there is a large body of opinion among ophthalmologists in support of our views. The Ophthalmic Group Committee has adopted the plan and it is submitted to the profession for approval. It is for this reason that I write to support Mr. Spencer Walker. I know of individual sight-testing opticians who will welcome the scheme, but we do not know what will be their opinion as a whole.

The main argument of ophthalmic surgeons opposed to the scheme is that opticians should not be allowed to do refractions and examine eyes. There is little need to say much to refute this, as most surgeons are fully aware that the optician can do refraction as well as the surgeon. What he cannot do is assess the importance of the error of refraction in the life of the patient, and this brings me to the main argument against the scheme among opticians. They assert that they should have professional status and be independent of medical control. This is clearly impossible, as the ophthalmic surgeon must be the one responsible for the welfare of the eyes of the community, and if he is to be responsible he must have control.

But why must the ophthalmologist be entirely responsible? For two very good reasons. The first is the diagnosis of early disease. It is true that the optician can in a large number of

cases recognize the presence of a disease or an abnormal condition, but there is that percentage of patients in which a pathological condition is overlooked. Even if the percentage of such cases is as low as 1 or 2, that is too many. The training of the optician in the pathology of the eye is quite inadequate, and short of a complete medical training must always be dangerously incomplete.

The second and more cogent reason is the assessment of the importance of a refractive error in each individual case. It is only the ophthalmic surgeon with his medical training who is able to decide whether an error of refraction requires correction, or whether other treatment, either locally or generally, is advisable. It is a common experience to see patients who have been supplied with glasses by an optician and in whom there is found some other and more important cause of their symptoms.—I am, etc.,

Ride.

FRANK HECKFORD.

SIR.—There is much to be said in favour of Mr. Spencer Walker's article on the ophthalmic surgeon and the optician. It has always seemed wrong to me that even the most enlightened ophthalmologists should have to spend much valuable time in prescribing presbyopic spectacles in order to live. There can be no objection to the handing over of the refractions to a sight-testing optician or medical auxiliary provided the patient has been first examined by a doctor and all question of disease eliminated. I believe that such a scheme obtains at the present time in the Royal Naval Medical Service, where opticians come into the category of Sick-berth Steward O.

But even if the opticians are willing to co-operate in such a scheme—and recent correspondence in the Press suggests that some of them at any rate regard themselves rather as consultants than as medical auxiliaries—there still remains the question of finance. From our point of view this may be rather a "bull" than a "bear" point. I do not know what the average sight-testing optician earns, but I should think his income is high, having regard to the price of spectacles and the fact that all classes, irrespective of their financial status, seem willing to buy elaborate spectacles. It is possible, therefore, that an optician may earn more than the State proposes to pay an ophthalmic surgeon, though this is mere conjecture, as, with customary delicacy, this all-important point has been omitted from the White Paper. Now, while we as a profession are notoriously unbusinesslike and take an altruistic view, no one would accuse the opticians of any lack of business acumen. The Minister of Health can hardly offer a higher salary to a medical auxiliary than he suggests for a doctor. I am sorry to finish in such a materialistic vein, but anyone who has read Sir John Anderson's admirable Budget speech will realize that inflation has already set in, and I do not wish to end my career on an inadequate fixed income.—I am, etc.,

Camberley.

LESLIE HARTLEY.

### What is Evidence?

SIR.—I was very sorry to see the article "Assessment of Blood-group Evidence" in the *Journal* of Jan. 22. Even had such an article appeared in a legal journal I should have found it remarkable, but finding it in a journal of medicine is almost beyond belief. For a writer presumably familiar with the reliability of blood-grouping tests and the unreliability of the testimony of witnesses and of subjective judgments of character, to indicate approval of Mr. Mullins in coming to his decision that "he did not, having heard and seen the wife, think she was of a type that commits adultery," frankly amazes me. Your writer goes on to say, "It would be an evil day for our courts if they ever felt obliged to elevate scientific evidence into a class by itself, instead of, as at present, keeping it on the same footing as other evidence." Had your writer said instead, "It would be an evil day for our courts if they ever felt obliged to base their decisions on facts instead of rumours and anonymous communications," I could not have been more astonished. At one stroke you have dealt the cause of the proper use of scientific proof a blow from which it may require literally years, not only in Great Britain but also in the United States, to recover.—I am, etc.,

Boston University, School of Medicine, Boston, MASSACHUSETTS. WILLIAM C. BOYD.

### To Boil or Not to Boil

SIR.—Within the last seven months two samples of milk, as supplied compulsorily to residents in a road, have been sent for bacteriological analysis to the Ministry of Health laboratory in the district. Necropsies of inoculated guinea-pigs gave one sample positive for *B. tuberculosis*, the other for *Brucella abortus*. In the fourteen houses in this small road section, supplied by the one vendor, are living fourteen young children. No alternative milk supply is purchasable, yet public advice to make the milk safe by boiling is not thought desirable. The M.O.H. has been consulted, but replies that "we public health people" consider that general advice to boil milk should be reserved in case a typhoid or other epidemic should make such recommendation a matter of extreme urgency.

So fourteen young children, in homes where extremely high standards of child care are maintained, are left unprotected by the guardians of public health, although the milk supply is demonstrably toxic. The two households who submitted the samples for analysis were "strongly advised" to boil all milk, but this warning would only directly affect two of the fourteen children. Very many others in the area supplied from the same source must also be at risk. If a pasteurized supply is impossible to obtain while the war lasts should not purchasers be warned that milk safety cannot be guaranteed, and that milk should therefore be brought to the boil before allowing children to consume it?—I am, etc.,

ESTHER CARLING.

### Mastoiditis and Mastoidectomy

SIR.—I am very glad of Mr. G. Gordon Mowat's reply (April 8) to my letter on mastoiditis (March 18) because, as he generously states, I do write in very good faith. I feel that this is a very vital question for the medical profession and should be widely ventilated.

The word "mastoid" brings a feeling of dread to the general public. They of course do not look upon it as a very strong bone protecting the ear and giving a point of support to important muscles of the neck. The public have come to think of it as a dread new disease which requires an operation of a very serious and often fatal nature, with frequent great disfigurement and possible facial paralysis, possible deafness, a continuation of and aggravation of the ear discharge with very painful and prolonged dressings after operation.

The operation of mastoidectomy, I believe, originated in Germany and has been performed in this country for roughly the past forty years. The operation became very popular with otologists from about 1910 onwards, and, I contend, became quite a menace to the public. After the last war its popularity came to its full swing. For several years the cry was for immediate operation. This naturally was followed by a great many tragic deaths of healthy people, mostly children and young adults. To break into the mastoid bone, get into an acutely infected middle ear, and then (as was so often done) to chisel away into the attic and remove the bone which separated this septic cavity from the brain was, in my opinion, very faulty surgical technique, and simply asking for trouble.

The frequency of meningitis was alarming, and so many young people died of this in a matter of three or four days to a week after the mastoid operation that it began to alarm otologists. A wiser attitude prevailed, and the practice of waiting until the acute stage of the otitis media had passed became the general rule. Nevertheless, even this wiser policy got a very bad hearing when Dr. Douglas Guthrie of Edinburgh first proposed it at a meeting of the Otolological Society in London some years ago. Now, I am glad to say, his words have sunk in, and, I repeat, it is now generally accepted that it is extremely dangerous to operate upon an acutely infected middle ear. By operation I do not mean paracentesis of the tympanic membrane, for that, I contend, is a proper course to take, and is just assisting Nature rather than waiting until the tympanic membrane ruptures, and it is a proper surgical technique. "Where there is pus, let it out."

Redness and swelling behind the ear, with the ear pushed forward, and a raised temperature, etc., is no reason for mastoid operation. The infection has not passed through the mastoid bone. It would be ridiculous to think that it could do so

## CORRESPONDENCE

636 MAY 6, 1944

in this hard powerful bone in the space of a day or two, is was contended by those who believed that osteitis of the mastoid bone had taken place. The infection passes along the meatus and infiltrates into the tissues at the back of the ear, causing those so-called symptoms warranting mastoidectomy. This is proved by the great frequency of all those symptoms in furunculosis of the auditory meatus. I have seen similar symptoms after a boxer has received a hard blow over the ear. I have seen similar symptoms in a child with pediculosis capitis, which caused scratching and inflammation of the scalp.

I cannot believe that Mr. Gordon Mowat really means that all cases with a discharge from the middle ear should be subjected to the drastic course of having a mastoid operation performed within six weeks of the commencement of the discharge. How soon would he operate? What mass operation there would be; for a discharging ear has happened to a great many people at some time of their lives. Even furuncle of the ear often takes weeks to clear up, let alone an otorrhoea. Mastoidectomy is a very drastic way of stopping a discharge from the ear, and, alas, it so frequently does not succeed. Personally I would rather have a discharging ear than undergo mastoidectomy, and I know of many more who also would think it the lesser of two evils. However, as Mr. Gordon Mowat says, the symptoms do subside, the discharge does dry up, and very often the perforation itself heals also (the last is my own remark, the first two are Mr. Mowat's), and I simply cannot agree that a state of mastoiditis or osteitis of the mastoid bone remains. So why operate? The danger of meningitis or of abscess of the brain is immeasurably greater when the defences are all chiselled away than when, at the worst, the mucous membrane lining of the middle ear is thickened the discharge is of a chronic non-virulent nature, and Nature herself has sealed off all sources of danger. This is what does happen and always has happened, and it results in a very harmless state of affairs for the patient. The only cases of meningitis and of abscess of the brain I have seen as a sequel to otitis media have been those on which mastoidectomy has been performed. Cases of previous radical or modified radical operation are placed in Grade IV. This is very definite, and shows what medical authority thinks of the expectation of life or of health of anyone who has undergone the mastoid operation.

The alternative to the mastoid operation is treatment of a very simple nature:

- (1) First drop pure hydrogen peroxide into the affected ear; gently mop up secretion; do this several times until the meatus is clear as possible.
- (2) Rest patient on affected side and apply as much heat to that side of the ear as possible.
- (3) It is generally best to give an aspirin or phenacetin powder twice daily to help the inflamed pharynx which originated the ear trouble; it is also soothing and helps to allay pain and allow sleep.
- (4) Great pain is nearly always stopped by dropping in pure methylated spirits, followed quickly, if the spirit itself causes too much of a feeling of burning in young children, by pouring in pure hydrogen peroxide after letting the spirit run out of the ear.
- (5) As the discharge becomes less, add one or two drachms of spir. vini meth. to one ounce of hydrogen peroxide and continue using this as ear-drops for some time.
- (6) Latterly use pure methylated spirit to complete the drying up and healing process: continue this for many weeks, filling the ear with spirit nightly and plugging with cotton-wool; the wool can be removed in the morning.
- (7) Sometimes, for a cellulitis behind the ear or irritation of the skin of the ear, 10% ichthyol in glycerin plain lint is required, and quickly allays inflammation and tenderness.

The general medical practitioner needs only patience, faith, and courage, and he will see results which will astound him.—I am, etc.,  
Edinburgh.

H. HILTON BROWN, M.B., D.P.H.

## Marriage and Parenthood

SIR.—Dr. E. F. Griffith's letter (April 15, p. 540) raises issues of paramount social importance at the present time, not only because there has never been a period as during the last five years when so many young and ignorant couples have rushed blindly into matrimony without the foggiest notion of its complexities, but also because many of the difficulties he outlines will be multiplied and accentuated when the fighting men return to the womenfolk on demobilization. His letter is in point of fact, an amplification of Prof. J. A. Ryle's letter in the *Lancet* of March 27, 1943. Both Prof. Ryle and Dr.

Griffith tend to suggest that doctors are in great part to blame for the ignorance of the public, but I think this is hardly fair. My experience has been that people will ask their next-door neighbours or their friends or the chemist about these matters, any one in fact but the only person whose knowledge is sufficiently thorough to explain things properly—namely, the doctor.

Dr. Griffith states that young people should be encouraged to seek advice. So they should, but many difficulties will be encountered. Those who try will find that it is well-nigh impossible to cleave a way through the jungle of ignorance and prudery which surrounds the vast bulk of the population. It may sound incredible, but my experience goes to show that there are people who are actually prepared to believe that efforts to assist them spring not from a spirit of wanton and vulgar curiosity. I have even encountered a spirit of narrow-minded censoriousness in people who by their education and training should know better, and it is not until a high level of intelligence, coupled with a sound though non-medical education, is reached that one finds even a disposition to regard such matters with a reasonable degree of broad-mindedness. The education authorities are the prime culprits in respect of the public ignorance of sex, and not until they lay a satisfactory groundwork of sane sex education can any progress be made which will enable doctors to exercise their specific educative function.

Dr. Griffith and Prof. Ryle are pioneers, and like all pioneers are a generation ahead of their time. Their voices, I am afraid, stand very little chance of dispelling the prevailing ignorance and prudery of the masses.—I am, etc.,  
J. B. WRATHALL ROWE.

Harrow.

## Colonial Medical Service

SIR.—In your issue of March 25 Dr. Morgan is reported (p. 440) as saying in the House of Commons on March 16 that "the Colonial Medical Service was one of the worst in the world." The exact implication of this generalization and the data upon which Dr. Morgan relied in arriving at it are not easy to assess. But so far as it concerns Tanganyika, Dr. Morgan's statement is strangely misleading. If he means that the medical department is much understaffed I am in full accord with him, but I cannot suppose that his remarks will be of assistance to the Colonial Office in their efforts to rectify the deficiency.

If, however, Dr. Morgan refers to the qualifications or performance of the medical staff he displays gross ignorance of facts which a cursory examination of the reports on the Territory would speedily dispel. The European staff of the Medical Department of Tanganyika, which has been but little augmented in the past twenty years, has not only met all demands imposed by the growth of other Departments, but has extended its activities in numerous directions. During the war it has made large contributions in personnel to the military Services, and has not only maintained its peacetime activities but has borne a greatly increased burden by the examination and care of large numbers of military units stationed in connexion with the country, and a large amount of work and passing through the Department. There has been no etc., has fallen upon the Department. There has been no breakdown or suggestion of failure in the Department, despite all the additional work imposed upon a much reduced staff. Statements such as Dr. Morgan's are such welcome material for the propaganda organizations of our enemies that I feel strongly the need for contradiction.—I am, etc.,  
Boscombe.

J. B. DAVEY,  
Formerly, P.M.O., Tanganyika,  
recently S.M.O., Tanganyika.

## Tuberculin Patch Test

SIR.—Dr. Donald Paterson's tuberculin jelly patch test seems to have much to commend it, but in its place seems to be unnecessarily refined. All that is necessary to do a satisfactory patch test is either or acetone for cleaning the skin, a solid glass rod—such as is used for the instillation of ointment into the eye—and a bottle of crude tuberculin. After cleaning

the skin a drop of tuberculin, the size of which can be controlled within fairly wide limits, is applied to the desired site (since reading Dr. Paterson's article I have been using the "V" sign), and covered with elastoplast. This idea was obtained from an article by Maurice Grozin in the *American Review of Tuberculosis*, Oct., 1943.—I am, etc.,

Penzance.

G. A. M. HALL.

### Tonsillectomy in Children

SIR,—I understand that Mr. Carew-Shaw fears that an evil-minded person who read my letter of March 11 without having seen his of Feb. 19 might think that I had imposed a slur upon his character and reputation. Certainly I had no such intention when I wrote, nor can I even now see that any such interpretation can be put upon my words; but I owe him the sincerest apology for any hurt that I may have done him.

I wrote that letter because of two causes that I have had at heart for many years. The one is opposition to the excessive removal of tonsils. I thought that in minds less acute than Mr. Carew-Shaw's and in hands less skilful his letter might result in an increase in the number of these operations just at the time when we have in view the hope that they may be reduced to reasonable proportions.

The other is the principle that has been accepted by the people that in future there shall no longer be one medicine for the rich and another for the poor. I feared that Mr. Carew-Shaw's contrast of the "private" with the "hospital" patient might result in the same suggestion of a varied service that has arisen under the N.H.I. between the "private" and the "panel" patient, and I felt that any such suggestion should be scotched at once. In trying to do this I used an expression that I had intended to be rhetorical and to suggest a *reductio ad absurdum*; but apparently it can be interpreted as being a slur upon Mr. Carew-Shaw, whereas, in fact, he has enrolled himself among those who have determined that the old conditions shall no longer remain.

I have long contended that the criticisms that have so freely been made against our profession of recent years are due not to any original sin inherent in the members of it but to the conditions under which we have to work; and that it must be the purpose of the medical statesman to provide conditions that will afford the opportunity to give equal service to all. At that and at that only was I aiming when I wrote my letter.—I am, etc.,

Guy's Hospital, S E

T. B. LAYTON.

## Obituary

### J. ARGYLL CAMPBELL, M.D., D.Sc.

We regret to announce the death at Inverness on April 20 of Dr. J. Argyll Campbell, who had been a member of the research staff of the National Institute for Medical Research at Hampstead for 23 years.

James Argyll Campbell, son of James Colin Campbell, M.D., of Bute and Brisbane, was born in Australia on March 30, 1884, and was educated at Brisbane Grammar School and the University of Edinburgh, where he had a brilliant career, gaining nine university medals; he also won the Aitken Carlyle bursarship, the Carnegie and Crichton scholarships, and on two occasions the Vans Dunlop scholarship. He graduated M.B., B.Ch. (with honours) in 1909, received high commendation for his M.D. thesis in 1912, and was awarded the D.Sc. in physiology in 1914. He worked as research assistant to Sir E. Sharpey-Schafer in the physiological department at Edinburgh from 1909 to 1913, in which year he was appointed professor of physiology at the Government School of Medicine, Singapore, retaining that office until he came to London in 1921 to work under the Medical Research Council. During his time in Singapore Argyll Campbell served on a commission of inquiry in one of the Malay States, and was a member of the Medical Advisory Committee on Food Control in Singapore. He contributed to this and other journals a number of important papers on physiological subjects and on lung tumours in

mice and in man, and collaborated in 1925 with Sir Leonard Hill in writing *Health and Environment*, and in 1934 with the late E. P. Poulton in writing *Oxygen and Carbon Dioxide Therapy*. The physiology of oxygen and its uses in medicine had attracted him for many years, and he became a recognized authority on that subject as well as on cancer of the lung.

In his youth Argyll Campbell had been a keen cricketer, playing for Edinburgh University and in inter-State cricket in Malaya. During recent years he was greatly handicapped by deafness. He gave ungrudging assistance to this *Journal* for some years as a leader-writer on those subjects in which he had special knowledge.

### J. MCK. CATTELL

James McKeen Cattell, the American psychologist, who died recently at the age of 83, has been described as the organizer of American science. He was, more strictly, its publisher, for he was the founder and editor of several scientific periodicals, both for the scientifically educated and for those who spoke only a lay language. Cattell made his reputation from the 'eighties onwards in the field of experimental psychology, and psychological research was one of his chief interests to the end of his life. At the turn of the century he was by far the most likely candidate for active leadership in American psychology, but as the years went on he found his greater work in the dissemination of scientific knowledge in general, and thus became a leader and servant of American science as a whole rather than of psychology only. He is said to have been the first American scientist to recognize the great power of print in the promotion of science; the attitude of some scientists, even among the greatest, has been that the publication of scientific work beyond the austere walls of a learned society vulgarized it in some way and perhaps hindered its fulfilment. Cattell took the opposite view. His chief organ was the weekly journal *Science*, published in Pennsylvania, and very much resembling *Nature* in this country. He edited *Science* from 1894 onwards, and it was his boast to have produced an impartial journal in which for half a century any reputable man of science could set forth his honest opinions, however controversial or however much at variance with accepted theory, about any matter of importance. A more popular presentation was afforded by another periodical, *The Scientific Monthly*, and he founded or helped to found a number of other journals dealing with psychology, philosophy, scientific methods, and education. Another useful labour of his was *American Men of Science*, of which the first edition was published in 1906 and the seventh is now in the press. This work called for laborious compilation and fine editing, the kind of task Cattell greatly enjoyed: it was a means of disseminating scientific knowledge in the form of biography.

Cattell was a leading figure in the American Association for the Advancement of Science. He induced it to establish a Section of Education, and himself worked to make it a success. In 1921 he organized the Psychological Corporation. This enabled psychologists, by undertaking practical service for business organizations and individuals, to earn funds to prosecute further psychological research. The venture was owned and operated by psychologists, not for private gain but for the advancement of their science. It now enjoys an income of £120,000 a year. Cattell was president of the American Psychological Society in 1895 and of the ninth International Congress of Psychology in 1929. At the age of 28 he was a professor in the University of Pennsylvania, and at the age of 31 became head of the department of psychology at Columbia. He was dismissed from this latter post in 1917 on a charge of "treason" because he had signed a petition urging Congress not to declare war, but his reputation suffered no lasting harm from that setback. He was a man of highly original character, fearless in urging what he believed.

The following well-known medical men have died abroad: Dr. BERNARD SACHS, an eminent New York neurologist, aged 80, author of *Mental and Nervous Disease in Children* (1926), *Nervous and Mental Disorders from Birth through Adolescence*, and *Keenly your Children Normal* (1936); Dr. LEO WALLACE DEAN, a prominent nose and throat specialist of St. Louis and editor since 1927 of *Annals of Otolaryngology, Rhinology and Laryngology*, aged 70.

## Universities and Colleges

### ROYAL COLLEGE OF PHYSICIANS OF LONDON

#### Election of Fellows

At a meeting of the College held on April 27, with Lord Moran, President, in the chair, the following were elected Fellows:

Norman Kletts, M.B. (Manchester); Dr. W. Winnicott, M.R.C.S. (London); S. E. Tanner, M.D. (Leicester); T. C. St. C. Morton, D.B.E., M.D. (R.A.F.); William Gunn, M.B. (London); A. Wilson Jill, M.D. (Newcastle, Staffs); C. N. Armstrong, M.D. (Newcastle-upon-Tyne); P. H. O'Donovan, M.D. (Nottingham); A. S. Wesson, A.D., F.R.C.S. (London); R. W. Brookfield, M.D. (Liverpool); I. A. Clegg, M.B. (London); W. E. Rees, M.D. (Swansea); P. E. T. Hancock, M.B. (London); A. B. Taylor, M.D. (Birmingham); T. F. Jewer, M.D. (Bristol); I. J. Wood, M.B.E., M.D., F.R.A.C.P. (Australia); G. B. Mitchell-Heggs, M.D. (London); R. E. Tunbridge, A.D. (Leeds); W. I. Card, M.D. (London); C. H. Stuart-Harris, A.D. (London); F. Graham Lescher, M.C., M.D. (Derby); C. T. Potter, M.D. (London); Sir Rupert Briercliffe, C.M.G., O.B.E., M.D. (Barbados); C. G. Barnes, M.D. (London); J. R. Rees, M.D. (London); A. R. Gilchrist, M.D. (Edinburgh); G. L. Taylor, M.D. (Cambridge); Alexander Fleming, F.R.S., F.R.C.S. (London); J. K. Henderson, M.D., F.R.C.P. (Edinburgh); Lieut.-Gen. Sir Alexander Hood, K.C.B., C.B.E., M.D.; Col. W. S. Middleton, A.D., F.A.C.P. (America).

Dr. G. E. S. Ward was appointed external examiner in medicine or the Fellowship Examination of the Faculty of Radiologists. A. Clark, Dr. H. A. Dunlop, Dr. R. V. Christie, and Sir Robert Stanton-Woods were appointed examiners for the Diploma in Physical Medicine. Dr. Leonard Parsons and Dr. Donald Paterson were appointed representatives to attend the conference of the National Association of Maternity and Child Welfare Centres.

The following candidates, having satisfied the Censors' Board, were admitted members:

I. Ansell, M.B., Sheila T. E. Callender, M.D., Joyce A. Keeping, M.D., H. Lim, M.B., Fl. Lieut. D. S. Munroe, R.C.A.F., Y. H. Ng, M.B., apt. C. G. Phillips, R.A.M.C., Flying Officer O. L. S. Scott, R.A.F., apt. P. J. Sweeney, R.A.M.C., G. T. G. Thomas, M.B., Col. J. R. D. Webb, M.B.E., I.M.S.

Licences to practise were conferred upon the following 146 candidates (including 21 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the necessary by-laws:

C. C. A. Adeniyi-Jones, T. B. Anderson, W. A. Ashford Hodges, C. G. Attenborough, D. B. Austin, J. P. Barham, J. A. Barlas, D. V. Bates, R. L. atten, M. A. Bazett, M. Bendit, Jean G. Brabner, D. L. Broadhead, Jean A. roughston-Alecock, A. Brown, G. L. Bunton, E. Burman, R. Cannon, McC. Carmichael, Frances N. Carr, A. P. Chaudhuri, Peggy J. Clark, J. M. Clement, S. Coffey, W. R. Cole, M. D. M. Collins, A. Comfort, A. A. Condon, G. N. Cooke, W. E. Craddock, J. A. Daff, J. E. Davies, C. Dawson, C. E. Dent, A. B. Dickie, Mary P. Douglas, I. A. Dudgeon, I. A. Duncan, W. J. D. Eberle, D. A. W. Edwards, G. K. Emsley, L. English, A. M. Evans, E. A. Fairburn, Mary Farquharson, T. R. Arrimond, R. L. M. Ferrari, C. G. Fox, S. Freedman, J. Fry, J. H. Gibson, I. McC. Giles, M. T. Gillies, M. L. Grime, B. Green, B. V. I. Greenish, Cecile Greig, S. C. Harper, H. L. Harris, W. R. Harrison, C. J. V. Hellivell, M. Hill, C. B. Holmes, H. Howell-Jones, Rachael C. A. Hunter, I. G. Jackson, D. M. M. Jones, J. G. P. Jones, V. H. Jones, H. Kaufman, M. D. Leates, J. V. Kent, A. C. de C. Kerr, Eileen Keveney, June M. Kingan, Elizabeth M. Kingsley Piers, Joyce E. Landau, F. W. Lapage, L. G. H. e Clercq, J. C. S. Leverton, L. N. Lightstone, D. W. R. Lyle, J. D. M. Lytle, F. M. MacDonald, P. N. MacGinnis, I. L. McKelvie, J. L. F. Maine, heila M. Martin, M. B. Matthews, E. V. M. Medill, J. L. Middleton, I. Milton, Stella M. Murray, Constance B. S. Napier, R. W. Nash, H. M. Joorooya, K. W. Oldham, K. Owen, C. R. Oyler, D. B. L. Pailthorpe, E. Pembrey, P. B. Philip-Smith, T. L. C. Shalom, Patricia E. Sichel, O. A. Silis, P. H. Smith, W. H. R. mith, H. P. Speed, S. J. Steel, T. R. Steen, J. W. Stewart, Catherine Storr, W. Suleiman, J. L. Taylor, G. H. Tee, Barbara K. Thompson, D. A. Tilsley, P. Todd, W. G. Toole, F. I. Tovey, P. M. Tow, D. R. D. Vanstone, H. H. D. Veale, J. L. Wakelin, Jean M. Watson, B. L. Whitehead, J. D. A. Whitehaw, Marjorie J. Williams, J. L. Winkler, M. P. Winstanley, A. B. Wood, J. E. Wood, G. S. Yeoh.

Diplomas in Ophthalmic Medicine and Surgery (17), and Medical Radiology (5) were granted, jointly with the Royal College of Surgeons of England to the persons whose names were published in a report of the Royal College of Surgeons of England in the Journal of March 18 (p. 409). Diplomas in Child Health were granted to the 16 persons whose names were published in the report of the meeting of the Royal College of Surgeons of England in the Journal of April 29 (p. 605).

### UNIVERSITY OF OXFORD

In Congregation on April 3 the following medical degrees were conferred:

B.M., B.Ch.—J. B. Jeffries, W. S. Hamilton, W. E. Ormerod, G. R. enning, R. G. Harrison, T. Bell, P. P. H. Schmidt, Margaret M. Shattock, oan M. Levitt, and V. W. Zetlin and J. M. K. Marsh (in absence).

### UNIVERSITY OF CAMBRIDGE

The Linacre Lecture will be delivered by Col. Elliott C. Cutler, M.D., Chief Consultant in Surgery, U.S. Army, European Theatre of Operations, Moseley Professor of Surgery in Harvard University, to-day (Saturday, May 6) at 5 p.m., in the Lecture Room of the Anatomy School. The title of the lecture is "A Surgeon Looks at Two Wars."

The following have been approved for the degree of M.D. in absence: T. B. L. Bryan, A. J. Daly, S. T. Anning.

## Medical Notes in Parliament

### Penicillin Clinical Trials Committee

Answering Major Lyons on April 19 Mr. ATTLEE said the only change in membership of the Penicillin Clinical Trials Committee (set up by the Medical Research Council) since a previous answer on June 10, 1943, had been the appointment of six additional members. A report on the use of penicillin in treating war wounds was published on March 24 as Medical Research Council War Memorandum No. 12. A full account of work done at one of the main centres where trials were being made was published in the *British Medical Journal* on April 15. Further reports were being prepared. There was close contact between the Council and the firms manufacturing penicillin, who were represented on it.

Mr. LEVY: Is my right hon. friend aware that the *British Medical Journal* is a very illuminating journal, which ought to be circulated much more widely than it has been in the past?

Mr. ATTLEE later named the present members of the Committee, as follows: Prof. H. R. Dean (chairman), Prof. J. H. Burn, Dr. A. N. Drury, Surg. Vice-Admiral Sir Sheldon Dudley, Prof. A. Fleming, Prof. H. W. Florey, Dr. A. M. H. Gray, Dr. P. Hartley, Mr. R. Vaughan-Hudson, Air Vice-Marshal G. L. Keynes, Prof. J. R. Learmonth, Major-Gen. L. T. Poole, Dr. C. M. Scott, Dr. J. W. Trevan, Prof. R. V. Christie (secretary), and Prof. L. P. Garrod (assistant secretary).

### Gold Treatment of Arthritis

On April 20 Major LYONS inquired what was being done by the Ministry of Health in the development of the gold treatment for arthritis. Mr. WILLINK said clinical research into the value and correct dosage of gold salts in this form of rheumatic disease had been continued by the Empire Rheumatism Council, whose latest report said that no definite conclusions could yet be announced. The results reported as having been obtained by this form of treatment up to the present by no means justified any claim that it was uniformly successful.

### Increase in Short-term Sickness

Mr. WILLINK, answering Sir Henry Morris-Jones on April 20, said sickness benefit claims of approved societies showed a material increase in 1942 and a further rise in 1943, as compared with the pre-war average, in short-term sickness among insured persons, both men and women. It was not possible to state the precise extent of the increase. There was no statistical information available on sickness among domestic housewives. Detailed information on mortality rates was not yet available, but a provisional count indicated that the death rate in 1943 was slightly higher, at 11.1 per 1,000 population, than the figure of 10.5 recorded for 1942.

### Mental Health Services

In reply on April 27 to Mr. Ritson Mr. WILLINK said it would not be feasible to undertake a full restatement of the law of lunacy before the introduction of the National Health Service. At this stage, therefore, it was proposed only to make such amendments as were needed to enable the administration of the mental health services to be included in the one comprehensive service. These would be discussed with the local authorities and others concerned. No general survey of the mental health services was contemplated, but a special survey of certain important aspects, with particular regard to the provision for neurosis, was in progress.

**Tuberculous Ex-Service Men.**—Mr. McNEIL on April 4 asked the Secretary of State for Scotland whether there was any priority of medical treatment for ex-Service men afflicted with tuberculosis in any of its forms, or whether medical officers of health, in granting priorities of treatment, had regard solely to the medical needs of the patient. Mr. JOHNSTON replied that local authorities gave the necessary treatment as quickly as possible to ex-Service men suffering from any form of tuberculosis. Where sanatorium treatment was not required this usually presented no difficulty. Most local authorities, however, had a waiting list of tuberculous patients who required

Disorders of the Skin

# THE PRACTITIONER

Month by month THE PRACTITIONER provides the medical profession with carefully prepared articles on selected aspects of medical practice. Each issue is designed as a monthly aid in post-graduate study. Thus the January number dealt with "Problems of Rheumatism"; February with "Diseases of the Eye"; March with "Gynaecology"; April with "Indigestion" (special number, price 5/-). In addition to the monthly symposia THE PRACTITIONER brings to the notice of subscribers advances in medicine and surgery, practical points culled from the world's medical literature, notes and queries, and reviews of books.

## CONTENTS OF THE MAY ISSUE (Symposium on Skin Disorders)

- Sulphonamides in Dermatology.*  
By H. W. Barber, M.B., F.R.C.P.  
*Scabies.* By Henry MacCormac, C.B.E., M.D., F.R.C.P.  
*The Causes and Treatment of Acute Dermatitis.*  
By J. Ferguson Smith, M.D.  
*Acne Vulgaris.* By John T. Ingram, M.D., F.R.C.P.  
*Skin Disorders in the New-born Infant.*  
By J. L. Henderson, M.D., F.R.C.P. (Ed.)  
*The Therapeutic Use of Penicillin.*  
By Professor Lawrence P. Garrod, M.D., F.R.C.P.  
*Heredity of Blood Groups.* By R. M. Walker, M.D.  
*The Treatment of Infections of the Hand: the Necessity for a New Approach.* By David Patey, M.S., F.R.C.S.  
*The Interpretation of Physical Signs. V.—In Otolaryngology.*  
By F. C. Ormerod, M.D., F.R.C.S.

The JUNE issue will deal with

## DISORDERS IN WARM WEATHER

Through a recent increase in the paper ration allowed by the Paper Controller to all periodicals, THE PRACTITIONER is again in a position to enrol a limited number of new subscribers. The first four issues of the year are now entirely out of print. New subscriptions are invited from the May issue onwards, at a cost of £2 2s. per annum, post free at home and abroad. Single copies may be purchased at 4/- post free. Orders with remittances should be sent to:—

The Publisher, THE PRACTITIONER, 5, Bentinck Street, London, W.1.

## 'NEO-HALARSINE'

TRADE MARK

BRAND

## arsphenoxide tartrate

has been produced specially to meet the growing demand for an arsenical suited to the shorter and more intensive methods of treating syphilis. Repeated tests indicate that, both in the destruction of superficial treponemata and in the reversal of positive serological reactions, 'Neo-Halarsine' compares favourably with neoarsphenamine.

The average dose for an adult man is 0.09 gramme, for a woman 0.06 gramme.

Solutions retain their full therapeutic efficacy and freedom from toxicity for at least twelve hours after being made up.

Supplied in ampoules of 0.045, 0.06 and 0.09 gramme packed singly or in boxes of ten.

## The Services

Air Vice-Marshal A. F. Rook, O.B.E., has been appointed an Honorary Physician to the King in succession to Group Capt. G. S. Marshall, O.B.E., who has vacated the appointment on retirement from the R.A.F.

Capt. G. H. A. Simmons, R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in the field and Brig. (Temp.) H. G. Furnell, C.B.E., D.S.O., has been mentioned in recognition of gallant and distinguished services in the South-West Pacific.

## Medical News

The *Practitioner* announces with regret that, owing to age, Sir Humphry Rolleston has had to resign from the position of editor, which he has so successfully held since 1928. Until further notice Dr. Alan Moncrieff, associate editor since 1934, will act as editor.

At the annual general meeting of the Section of Psychiatry of the Royal Society of Medicine to be held at 1, Wimpole Street, W., on Tuesday, May 9, at 5 p.m. a discussion on morale will be opened by Surg. Lieut. G. Garmany, Lieut.-Col. G. R. Hargreaves, Wing Cmdr. J. H. Hunt, and Dr. A. B. Stokes.

A meeting of the Tuberculosis Association will be held at Manson House, 26, Portland Place, W., on Friday, May 19, when Surg. Capt. W. D. W. Brooks and Dr. A. K. Miller will open a discussion on treatment of the minimal lesion as found by mass radiography. Dr. Joseph Smart will give a short paper on two unusual cases of asthma.

The summer meeting of the Association of Industrial Medical Officers will be held in Birmingham on Friday, May 19, and Saturday, May 20, under the chairmanship of Dr. J. C. Bridge. On Friday there will be a business meeting at the Queen's Hotel, New Street Station, at 4.30 (tea at 4 p.m.), followed by dinner at 6.30 for 7 p.m. at the White Horse Hotel, Congreve Street. On Saturday, at the Tatler News Theatre, Station Street, Mr. E. A. Nicoll will show the new British Council film "Accident Service," at 9.45 a.m. At the Birmingham Accident Hospital, Bath Row, at 11 a.m., a discussion on "Rehabilitation and Industry" will be opened by Prof. Seymour Barling, Mr. William Gissane, Dr. N. T. Glynn, and Mr. G. M. Farrer. Luncheon will be provided at the hospital at 1 o'clock. In the afternoon a tour of the new departments of the hospital has been arranged, followed at 3.15 p.m. by demonstrations and clinical cases. Arrangements for this meeting are in the hands of the local secretary—Dr. W. Jeaffreson Lloyd, Guest, Keen and Netticolds Ltd., Heath Street, Birmingham, 18.

A whole-day conference of the Nutrition Society will be held on Saturday, May 20, beginning at 10.50 a.m., at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, with the following programme: "Budgetary and Dietary Surveys of Families and Individuals, Part II," papers by Miss E. M. Widdowson and Dr. R. A. McCance ("Dietary Surveys by the Individual Method"); Dr. Gertrude Wagner ("Surveys of Methods used in Preparing and Cooking Food"); Dr. G. N. Jenkins, Dr. L. W. Mapson, and Miss M. Oliver ("Laboratory Assessment of Nutritive Value of Meals as Eaten"). Papers on Food Consumption: Data Obtained from Analyses of Institutional Diets will be read by (a) Miss E. M. Langley ("School Diets"); (b) Dr. M. Pyke ("Industrial Canteens"); (c) Dr. A. Lyall ("Hospital Diets"). The openers of the discussion will be Prof. V. H. Mottram, Mrs. Barbara Callow, Dr. C. P. Stewart, and Miss M. C. Broatch. Further details of the Nutrition Society can be obtained from the hon. secretary, Dr. Leslie J. Harris, Nutritional Laboratory, University Field Laboratories, Milton Road, Cambridge.

On May 2 representatives of the Royal College of Nursing discussed with the Minister of Health modern trends in the development of the nursing profession, especially in relation to a comprehensive health service. Lord Horder, who, as chairman of the College's Nursing Reconstruction Committee, accompanied the deputation, said that his committee had been greatly heartened at the speed with which the main recommendations on the committee's first report—that on the assistant nurse—had reached the Statute Book. He briefly outlined the committee's recommendations for a wider and more elastic basic training for the nurses of the future, to include an insight into preventive and social medicine, and experience in certain special branches of nursing not hitherto covered. In this way the young nurse would view the whole nursing field in better perspective, and her interest would be aroused to the scope and opportunity for service in branches at present sadly understaffed. Recognition of real student status for the nurse in training would have a far greater influence on recruitment than any other single measure.

## Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.) TELEPHONE: EUSTON 3353. TELEGRAMS: *Articulate Westcent, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London*.

### ANY QUESTIONS?

#### Frequency of Defaecation

*Q.—I have come across two patients who state that they are in better health when they defaecate only on alternate days than when they try to do so daily. In one patient a type of vagus nerve hyperactivity appeared to occur when daily defaecation was attempted. Can this be explained, and how should it be treated?*

*A.*—No satisfactory definition of constipation has ever been made and it would be difficult to construct a distribution curve of the normal frequency of evacuation of the bowel in this country, owing to excessive bowel consciousness and the advertisement of purgatives on the one hand, and the inhibitions produced by gearing humanity to modern industrial and transport conditions on the other. There is little reason to doubt, however, that there is a range of variation in the frequency of normal evacuation of the bowels, as in other rhythmic functions such as the pulse rate or menstruation. Some people defaecate twice daily, others are upset if they worry their intestines into a daily action and are much better if their bowels are opened only twice a week. The chief physical ill effects of constipation are hardening of the faeces, which may then cause fissures on expulsion, and distension of the bowel, which may bring about reflex disturbances or actual obstruction. None of these is likely to happen when defaecation occurs on alternate days. The psychological effects of constipation are much more subtle, inasmuch as training in bowel habit forms so large a part of the early education of the child. The normal bowel habit of an individual may be the resultant of several physiological and psychological forces, and the attempt to disturb it may well arouse unconscious anxiety. The patient should be assured that an action of the bowels on alternate days is perfectly normal, and that attempts at interference are undesirable.

#### Marital Difficulties and Service Life

*Q.—I am concerned about a delicate problem, which has grown from one or two isolated cases to a number which is assuming proportions I feel need consideration. The patients are married men and all have the same complaint—namely, the inability to obtain an erection when desiring intercourse. In each case the facts are materially as follows: (1) They are healthy, vigorous, active types performing their Service duties efficiently and without undue fatigue. (2) There is no evidence of constitutional or other organic disability. (3) All claim to be fond of their wives and affirm that it is no lack of love or desire on their part (a frequent cause of this disability in other cases). (4) All look forward with keen anticipation to intercourse on their periods of leave or time off. (5) In each case the lack of ability to obtain an erection has caused considerable mental upset to the man, frustration for the woman, and bids fair to upset marital happiness, which in any case, in wartime, is in none too stable a state. In some cases charges of unfaithfulness and lack of love have been made by the wives, which are quite understandable. Men return home or go on leave, possibly pre-occupied with Service problems, or concerned with matters other than domestic. I feel that the basis is a mental one rather than physical, and should I be glad of any help.*

*A.*—The problem of partial or complete impotence in men separated from their wives, especially on military service, can be understood in terms of the psycho-analytic libido theory. It is commonly observed that the good soldier "invests" much of his available emotional energy in an all-male group—i.e., in the questioner's words, he is preoccupied with Service matters. This often means a reanimation of an adolescent pattern of interests and loyalties: without such bonds morale and *esprit de corps* could not exist. To the extent of this change in "libido economy," the wife and home become more remote, the man's attitude divided. Like the adolescent, he nourishes a great fantasy of sexual potency, where in reality there is every gradation between this condition and com-

plete erotic estrangement. It is unfortunately true that the military uni-sexual milieu, devoted to destruction, is antagonistic to Eros, and that the very promiscuity of soldiers is mostly an attempt to allay the fear of impotence arising from this enforced mass regression to the "boys together" level. To the above predisposing situation must be added possible anxiety and rush to catch the earliest train, arrival in a fatigued condition, and the challenge of "proving" one's love and power as soon as possible. As put by a colleague: "He feels he ought to be lusty for his wife instead of settling down for a day or two. . . . He makes it a point of duty to try to do a star performance—and both take the first-night failure as something final." Anxiety and conscious preparation, inferiority, guilt, and suspicion complete the aetiology. In fact both partners have become desensitized and need a period of days to re-establish erotic intimacy. In sexual relations, as in digestion, psychology largely governs physiology.

As prophylaxis a general talk to married men proceeding on leave may dwell on these notions: the possible sense of strangeness, the happiness of a new courtship, the need for being rested and reattuned, and the error of being in too great a hurry. The tone must be friendly, reassuring, and not suggest failure, but rather assume the naturalness of such a state of affairs in most couples separated for a time. In treatment after such an occurrence the wife's doctor may need to co-operate on similar lines, while the man's M.O. prepares him as above for the next occasion—aided in some cases by a suggestive "tonic." Unit M.O.'s should enlist the help—not necessarily by referring the men—of Service psychiatrists, whose duty it is to watch over the mental health of the Forces.

#### Vaccines for Arthritis?

**Q.**—Would you advise treatment by vaccines in a case of arthritis of the spine where there is no obvious locus of infection?

**A.**—The late Dr. Okell, formerly professor of bacteriology at University College Hospital, who suffered from spondylitis, expressed the following opinion: "Is it reasonable to treat a supposed infective disease with a vaccine made from a micro-organism when there is no acceptable evidence that disease is caused by the micro-organism in question? The answer must be, No. . . . There seems no convincing evidence that a human disease has ever been cured or significantly benefited by vaccine treatment" (*Reports on Chronic Rheumatic Diseases*, R.C.P., 1937, 3, 3). No doubt enthusiasts may be found to disagree with this conclusion, but the whole article is worthy of careful study. I am definitely of opinion that in such a case as the question refers to vaccines would be useless, and I have seen many cases in which treatment by vaccines has made the victim of arthritis worse, apparently from sensitization. Rest and general measures to build up resistance furnish in most cases the safest and best line of treatment, though good results have been obtained by deep x rays in expert hands.

#### B. Coli in Urine

**Q.**—I would like advice about a small girl aged 6 with *B. coli* infection of the urinary tract. She was treated for about three months with alkali without benefit; to this was added a course of sulphapyridine, the alkali being continued—again no result. What further treatment should be tried?

**A.**—Treatment with any of the sulphonamides should have cleared up an uncomplicated urinary tract infection with *B. coli*. It should first be determined by bacteriological examination of the urine whether the same infection still exists. Persistence might be due to the co-existence or substitution of another infection by an organism not susceptible to sulphonamides, such as *Str. faecalis*. This infection responds only to mandelic acid treatment, which is also worth trying in the presence of atypical and sulphonamide-resistant coliform bacilli. If antiseptic treatment still fails, there is likely to be some abnormality of the urinary tract, such as a hydro-nephrosis, predisposing to infection and its continuance.

It is assumed in this answer that an infection is known certainly to exist, but it should perhaps be pointed out that female specimens of urine always contain cells and bacteria, including sometimes *B. coli*, which have merely been washed off the vulva. These bacteria may multiply rapidly in the specimen if its examination is delayed, and produce the picture of at least a bacilluria. There are objections to catheterizing a child, but if the diagnosis is in doubt, and prolonged treatment or elaborate further investigation depend on it, an uncontaminated specimen must be obtained.

#### Paralysis Agitans

**Q.**—Can you suggest further treatment for a case of paralysis agitans in a retired medical officer who has spent some years in tropical Africa? Sedative drugs, gland extracts, and vitamin B have been tried without benefit.

**A.**—It is unlikely that residence in the Tropics will have influenced the onset of paralysis agitans. In this case the first point to be decided is whether it is a post-encephalitic syndrome or whether it

is secondary to vascular changes, or simply the paralysis agitans of old age. Because of the chronicity of the condition, very many different kinds of treatment have been tried; most of them have not shown any advantage over more usually accepted drugs such as the alkaloids atropine, hyoscine, and scopolamine. An excellent review of the effects of various kinds of treatment will be found in the clinical study by J. B. Neal entitled *Encephalitis*, published in New York in 1942. It is shown quite clearly that vitamin therapy and gland extracts have no place in symptomatic treatment, whilst sedative drugs have a very slight effect.

In using the alkaloids it is most important to push the dosage to a high level, if necessary, to produce relief of symptoms, and it is also advisable to try different combinations, since there is a great individual variation in response. To do this the patient should, of course, be under observation. Treatment should be begun with small doses and pushed to the limit of the patient's tolerance, care being taken that he has not any evidence of glaucoma. The beneficial effect of persistent exercise and physiotherapy must be remembered.

#### Implantation Cancer

**Q.**—We are all familiar with cancerous growth developing in a scar after operation for cancer (autogenous implantation), but has there ever been implantation of cancer in other wounds—e.g., a surgeon's hand? Has any case ever been recorded of cancer of the penis following sexual intercourse with a woman suffering from carcinoma of the cervix?

**A.**—There are no authentic reports of accidental homologous implantation of cancer in human beings. Deliberate experiments have been made to transplant cancer from one person to another. Thus Alibert allowed himself to be injected with ichorous material from a cancer of the breast (1808). In recent times Senn (1901) transplanted into himself a fragment of lymph node in which carcinomatous invasion had been demonstrated by the microscope. A nodule the size of a pea appeared at the implantation site and remained stationary for two weeks and then regressed.

We now know from experiments on animals that transplantation of cancer from one human being to another would not be likely to be successful in more than a small percentage of inoculations and then only under propitious circumstances—e.g., sterile grafts composed of many thousands of healthy cancer cells, and a near genetic relationship between host and graft. Accidental injury at an operation could not provide the necessary conditions. In a famous case in Paris about 15 years ago a house-surgeon accidentally pricked his hand with a needle which had been used to draw off fluid from a cystic mammary cancer; a sarcoma, which eventually caused death, developed at the site of the injury. This was not an "implantation cancer," since the tumour of the hand differed in structure from breast tumour.

#### Cerebral Thrombosis

**Q.**—What is the treatment for cerebral thrombosis?

**A.**—In the acute stage of cerebral arterial thrombosis, to which the question presumably refers, treatment is directed towards preventing extension of the thrombus by increasing cardiac efficiency, diminishing the clotting power of the blood, and reducing progression of arterial degeneration, which is the prime cause of the thrombus. (Any cause for the degeneration, such as renal disease, diabetes, or syphilis, should be sought.) Rest, fluids, and glucose are needed; purgation should be avoided, and, if fibrillation or cardiac embarrassment are present, digitalis should be given. Injections of strychnine may also help. The clotting time can be increased by injections of heparin, and sodium iodide by mouth is said to diminish the spread of atheroma, though this is very doubtful. Once the acute stage is passed the patient should be got up, and exercises, massage, and movements of the affected limbs should be undertaken. It is most important to keep the muscles working and the patient active.

#### Scissors Gait in Disseminated Sclerosis

**Q.**—Some time ago I became afflicted with disseminated sclerosis. My condition has recently improved, and I now need some rehabilitation exercises which will help me to counter the occasional blocking of left (affected) foot by right foot in walking. I attribute this to the fact that the right foot encroaches on the middle line, thus seeking centre of gravity, but impeding the already embarrassed left foot. This blocking is occasional only and does not seem to be due to definite paralysis or paresis. What remedial exercises are advisable to inculcate a correct sense of centre of gravity? My difficulty is present in walking only. I can stand up from my chair under my own power, and, unsupported, can use my companion hair brushes. I should also like to know where to obtain the latest references to this disease.

**A.**—The symptom which is complained of is surely a slight scissors gait, a more severe example of which is seen in Little's disease. It is due to spasticity which affects the adductor muscles. These occasionally go into spasm with consequent dragging of the leg over the midline. Sparring of the arms might be expected if the

weight of the disease were upon the dorsal spinal cord. I do not think there are any special exercises to relax the spasm, since it is due to over- and not under-action of the muscle. The most recent literature on disseminated sclerosis deals with the theory that it is caused by venous thrombosis in the central nervous system, and many of the references may be found in the *Archives of Neurology and Psychiatry* of the last two or three years.

#### Ridged Finger Nails

**Q.**—What are the causes and treatment of ridged finger nails? The patient has an asthmatic history and is subject to bronchitis.

**A.**—Ridged finger nails with transverse furrows are usually the consequence of some local or general disturbance of nutrition, and may thus be related to attacks of asthma or bronchitis. Median striation describes the ridge extending down the centre of the nail which can be remedied in many cases by small doses of x rays given by an expert.

#### Toxicity of Waterglass

**Q.**—Is waterglass a poison? I have heard of a man who drank about a tumblerful thinking it was lemonade, and died in about two days. In another instance waterglass was given in mistake for glucose. I cannot find any reference to waterglass as a poison in any of my books.

**A.**—Waterglass is a solution of sodium silicate of varying but high alkalinity, and the poisonous effects are most probably due to corrosive poisoning by free NaOH. It would have been interesting to have an estimation of the pH of the actual solution in cases mentioned. It is not unlikely that commercial samples of waterglass may be caustic from excess of alkali. Recent analyses in Germany have shown frequent adulteration with sulphur compounds and with sodium sulphate. When administered to dogs by mouth, waterglass caused inflammation and ecchymoses of the gastro-intestinal mucosa and congestion of the kidneys with infarction of the tubules. By intramuscular injection it was fatal. A dose of 15 gr. (1 g.) to rabbits induced alteration in the blood and fatty degeneration of the liver (*Legal Medicine and Toxicology*, Peterson, Hamis, and Webster, 2nd edition, vol. 2, W. B. Saunders Company, 1923). A case was reported by Eichhorst, 1920 (*Schweiz. med. Wschr.*, Nov. 25, 50, 1081), of a man who recovered after drinking by mistake 200 c.c. (6.75 fluid ounces). Prompt vomiting removed some of the substance, but enough remained to irritate the alimentary mucosa, causing vomiting, diarrhoea, severe abdominal pain, and occult bleeding. Excretion by the kidneys caused albuminuria, tube casts, sugar, acetone, and blood in the urine for a few days. The temperature and blood pressure were raised, and the blood picture showed lymphocytosis.

## LETTERS, NOTES, ETC.

#### Cecil Rowntree Memorial

Dr. A. C. SOMMERVILLE (hon. secretary, Medical Committee, Queen Victoria Hospital, East Grinstead, Sussex) writes: I should be very grateful if you would allow me to call the attention of any of your readers who might be interested in the proposal to establish a Cecil Rowntree Medical and Surgical Reference Library at the Queen Victoria Hospital, East Grinstead, to perpetuate the memory of the late Mr. Cecil Rowntree, F.R.C.S. Apart from his many other activities Mr. Rowntree was honorary surgeon to this hospital for upwards of twenty-five years. His colleagues and his many friends and patients in the neighbourhood will always remember his name with respect for his skill and with gratitude for his many kindnesses. It has therefore been decided to erect some permanent memorial to his name, and it is felt that there could be no better plan than the above. Gifts of books or the means of purchasing them will be gratefully received and acknowledged by the secretary-superintendent of the hospital.

#### Asthma in Children

Dr. ALEXANDER FRANCIS (London, W.1) writes: The article "Chronic Pulmonary Catarrh in Children," by Dr. Brian Taylor (April 1, p. 453), shows a lack of appreciation of the real significance of asthma and other bronchial symptoms. Dr. Brian Taylor evidently considers asthma a substantive disease. He says that in his asthma clinic in 1942, among 63 children under the age of 14, in only 12 cases "did it seem that the condition was a true allergic asthma." There is no such thing as "true allergic asthma." Asthma is only a symptom, comparable with pulmonary catarrh and sneezing. Various allergens are certainly capable of producing attacks of asthma, but they are no more the basic cause of the asthmatic condition than a chill producing an ague is the cause of malaria. I know of cases in which when the vasomotor system has been made stable allergens which once were highly irritating lose their power of producing an attack of asthma. This fetish of allergy seems to have warped our common sense. Undoubtedly climate and

certain subsoils have a marked effect upon the circulation; and if children suffering from pulmonary catarrh and asthma can be sent to Switzerland, as Dr. Brian Taylor suggests, they will lose their trouble, and provided they can live there long enough to establish a proper circulation they can return to this country and remain free, but this is impracticable and in the majority of cases unnecessary. Properly controlled courses of breathing exercises, muscular exercises, and cutaneous massage are essential, and immense good can be done by an almost imperceptible touch on the mucosa of the nasal septum with a fine cautery point. This, by reflex action through the nasal nerves on the sympathetic system, does much to regulate and stabilize the whole vasomotor system.

#### New Zealand Hospital on Fifth Army Front

We have received from the New Zealand Government Offices in London the following note: Within the sound of big guns booming out their hymn of hate New Zealanders man their hospital, the most forward complete hospital unit on the Fifth Army front in Italy. It is a little more than an hour's run from the front line, so that there is quick reception of wounded and sick persons from field ambulance and clearing stations. Less than a month before its establishment this New Zealand hospital was operating in the Middle East. For a short time the staff, with their equipment, were quartered on the east coast of Italy, but within a week of receiving orders to move they were again functioning as a hospital close up the Cassino front. The buildings occupied were formerly Fascist barracks and later a German military hospital. The buildings are modern, divided into bays, conveniently placed for division into wards. The walls are adorned with Fascist slogans which give the patients real entertainment: the highlight selected by the patients is this—"Battle is to men what maternity is to women."

#### Oiling Blankets

MESSRS. OLINOL LTD. (44, King Street, Manchester, 2) write: To obviate any possible further misunderstanding regarding "Olinol No. 1" (the product mentioned in the answer to the question "Oiling Blankets" in your *Journal* of April 15, p. 545) we would respectfully point out that we, and not our friends the Manchester Oil Refinery Ltd., are the originators, manufacturers, and sole distributors of "Olinol No. 1." Misunderstanding has in fact arisen in that several inquirers have written to the Manchester Oil Refinery as manufacturers of the product.

#### Sycosis Barbae

Col. S. G. S. HAUGHTON, I.M.S. (ret.) (Ely), writes: With reference to the question and answer in the *Journal* of April 8 (p. 511), in the majority of cases of sycosis barbae removal of the infected hairs, neither by forceps nor by x rays, is really necessary. A much simpler, quicker, and more satisfactory treatment is to paint the infected area twice a day with liq. ferri perchlor. fortis. Most cases are cured in one week; a few hairs may require extraction, but only a few. The patient after one week has merely to examine his face carefully each day and dab on the liq. ferri perchlor. fort. to any suspicious area. While under treatment no shaving is permitted. This treatment is slightly painful, but that is a minor detail compared with the quick result that is obtained. This treatment was referred to by Lieut.-Col. J. H. Smith, I.M.S. (ret.), a few years ago in the *Journal*. I have used liq. ferri perchlor. fort. in impetigo and sycosis barbae for years, and since using it have not had to try any other, as the result has always been both quick and satisfactory.

#### The Women's Parliament

The London Women's Parliament is an exuberant body. Over 700 delegates from factories, trade union branches, women's organizations, and professional and municipal bodies, and said to represent half a million London women, meet for occasional sessions. The report of the fourth session held recently has been published by the Women's Parliament (24, High Holborn, W.C.1) as a 4d pamphlet entitled *Health and Housing*. The record lacks the restraint of Hansard, and the British Parliament would be greatly affronted if the members took their places to the clicking of camera and the whir of sound track recorders, but at least the women go things done. A Health Bill was passed unanimously in a morning session. This Bill, among other provisions, called for an extension of the Factory Acts in order to establish minimum standards of health and welfare for women and young persons employed in transport and in every form of industry, with a part-time doctor in every enterprise employing 250 people or over, and a whole-time doctor wherever 3,000 or over are employed, also more maternity provision by local authorities, evening sessions at out-patient departments, and the development of real health education, all to be considered as steps towards the establishment of a comprehensive health service. Not content with passing a radical health measure in the morning, the Women's Parliament passed an equally radical housing measure in the afternoon.

# BRITISH MEDICAL JOURNAL

LONDON SATURDAY MAY 13 1944

## A NATIONAL HEALTH SERVICE

### REPORT OF THE COUNCIL OF THE B.M.A. TO THE REPRESENTATIVE BODY\*

The Council of the British Medical Association puts forward, for the consideration of the profession, the following draft statement of policy on the Government's White Paper on a National Health Service. It is intended that this statement should be the basis of discussion at meetings of the whole profession called by the Divisions throughout the country. At such meetings, which will be open to members and non-members of the Association alike, local professional opinion on this draft report should be expressed in the form of resolutions and instructions to Representatives at the Annual Representative Meeting to be opened on July 18, 1944.

There is appended to this report the replies of the Minister of Health to a series of questions put to him by the Representative Committee in order that the profession might have some fuller details on certain points before formulating its statement of policy. The Representative Committee has taken and is taking no other steps, and no negotiations will start until after the Representative Meeting in July. The statement in the form finally approved by the Representative Body will constitute the framework within which the Association's representatives on the negotiating body will act. A report from the negotiators will be submitted to an Annual or Special Meeting of the Representative Body before the Association is committed to any course of action. The remainder of the Annual Report of Council on this and other subjects will be found in the *Supplement* this week.

#### SOME GENERAL CONSIDERATIONS

1. The Government has put forward its first thoughts on a National Health Service in the form of a White Paper, asking that there shall be constructive criticism of them "in the hope that the legislative proposals which they will be submitting to Parliament may follow quickly and may be largely greeted." In response to this invitation the Association examines critically the spirit and form of the proposals put forward, and then proceeds to submit its own plan. It recognizes that criticism must be constructive, and relies on the Government's assurance that the proposals put forward are revisional only, and that they can be remoulded in the light of constructive criticism.

2. The medical profession is in complete agreement with the Government's aim to ensure that every man, woman, and child should be able to obtain all the advice and treatment and care which they may need in matters of health, and that the country's all resources are brought to bear upon reducing ill-health and promoting good health in all its citizens. The profession, particularly in the last quarter of a century, has again and again pressed upon the Government of the day developments and amplifications of health provision to this end. That pressure has been almost without avail. For example, the Interim Report of the Consultative Council on Medical and Allied Services (the Dawson Report) in 1920 outlined a scheme of primary and secondary health centres; the British Medical Association in 1930 and again in 1938 published its "General Medical Service for the Nation" which recommended the integration and co-ordination of the medical services; and in 1942 the Medical Planning Commission issued its Draft Interim Report which made further proposals for the organization of the medical services. All these documents are submitted to the Government for consideration.

3. The introduction to the Government White Paper on "A National Health Service" opens with the words: "The Government have announced that they intend to establish a comprehensive health service for everybody in this country." The emphasis in this opening sentence is on *Health*. One might expect this preamble to be followed by a description of the measures to be taken to promote and maintain the health of

the individual. The emphasis, however, shifts to sickness. It is a medical rather than a health service with which the Government appears to be really concerned—a service which is "an essential part of any wider proposals for social insurance which may be put into operation."

4. It is natural that public interest in health should be heightened in time of war. But it is ironical that the Government should begin to display a lively interest in organizing medical services on particular lines at a time when the medical profession and its organizations are almost wholly preoccupied with the problems of war, including the recruitment of doctors to the Forces. The doctors in civilian practice are greatly diminished in numbers as a result of recruitment to the Forces, and heavily overworked in consequence. Many of the younger and more active members of the profession who are vitally concerned with these proposals are in the Services, and effective consultation with them is exceedingly difficult.

5. A controversial issue has been raised at a time when the energies of the profession, like those of the whole community, should be directed to one objective—the winning of the war. It is recognized that housing and employment are social issues of first importance which should be faced in advance of the return of peace. But it is idle to suggest that the recasting of the form of health services cannot wait until there is time and opportunity to give them the care and thought they merit, and until our colleagues in the Forces are back in our counsels and their practices. There is suspicion, not without basis, that these proposals found their first inspiration in a desire to control an independent profession in order to control medical certification and so the outgoings of a Social Security Fund.

6. To agree upon the objects of national reconstruction in the field of health is not necessarily to approve the methods or the time-table proposed. Similarly, controversy on the working out of the plan need not obscure the fact that the ideal of a healthier people is, and always has been, the ideal of the medical profession. Our profession is rightly proud of its past and present contribution to human knowledge and happiness, its zeal and progress in scientific research, and the high standards it has imposed upon itself in its daily work. Nor need it apologize for claiming a prominent place in advising the Government on the paths to be followed and the methods to be employed in achieving this ideal of better health.

\* Members should keep this number of the *Journal* and the *Supplement*, which contains the Annual Report of Council.

There is a tendency in some quarters to foster the illusion that there is nothing good in the free institutions and the free professions of this country—an attitude usually accompanied by a belief in organization as the remedy for all our troubles.

7. Health is not mainly a question of medical services. The public must not be misled into believing that good health depends chiefly upon hospitals or clinics or doctors, or bottles of medicine, or indeed upon organization. Among the principal factors which determine a people's health are sanitation, provision of public water, housing, nutrition, conditions in factory and office, facilities for recreation, and education. Here is ample room for improvement, and for action by the State.

8. An individual's health depends in part on his or her own efforts, on healthy living, on a right attitude towards health and disease. In the field of health education there is still much to be done, if only to compete with that type of disease education which this country, like few others, allows, in the shape of patent medicine advertisement.

9. The work of doctors is conditioned by the state of medical knowledge. Investigation and research are the life blood of medical practice. The discovery of penicillin is likely to prove of more importance to the people of this country than all the health centres and all the intricacies of organization. The State's attitude to medical research may be judged by the fact that its official annual contribution to this work is a mere quarter of a million pounds! This is an indication of what a Treasury-conditioned outlook means.

10. The State is rightly concerned with problems of environment and prevention, with communicable disease, and with some forms of institutional provision. Another function of the State is to co-ordinate good existing facilities for the prevention and treatment of disease, whether they have evolved as a result of State or of independent action. Under its aegis much can be done which might otherwise remain undone.

11. To-day there are overlapping of organization, incoordination of effort, and gaps in service. These should be remedied by co-operative action between the State and the profession, and *not* by the assumption by the State of control of an expert field and those who work in it. The record of the State in health and medical matters contains little to justify the suggestion that either the Ministry of Health or local authorities are sufficiently equipped with knowledge and experience to assume so vast and so potentially dangerous a responsibility.

12. The medical profession has developed, over the centuries, as an independent profession. It has imposed upon itself strict standards, and the whole foundation of its work has been built in an atmosphere of intellectual and scientific freedom. Doctors have jealously fought for their freedom to think and to work in their own way, to hold views which seem to them right, and to practise their profession as they deem to be in the best interests of their patients. They must preserve their freedom to criticize the scientific work of their fellows and the organizations in which they work. The doctor's first allegiance is to his patient, and there has grown up a conception of a doctor-patient relationship which is confidential and wholly personal. Doctors are not prepared to sacrifice these things, and it is not in the public interest that they should be asked to do so. They are not prepared to substitute obedience to the State for loyalty to the patient.

13. In examining or promulgating any plans for a comprehensive medical service the medical profession will resist any control by the State, either political or administrative, which is inconsistent with their intellectual and professional freedom. They fear political influence in medical matters. They fear bureaucracy and red tape. They fear subservience of the clinical to the administrative. Theirs is essentially human work, related to human values, and they fear that it is likely to be submerged in a "service."

14. It is not enough to *promise* that there shall be no interference with the doctor-patient relationship, or that there shall be no regimentation of the profession. The plan must of itself, by the nature of its arrangements and provisions, ensure that there shall be no risk or chance of such interference or regimentation. And any plan must be free from features which suggest that the attack on these essential freedoms may be insidious and delayed rather than obvious and immediate.

15. It is in the light of these considerations that the Association has examined the White Paper. It is inclined to suspect that the inspiration of the Government's document is political rather than medical. It certainly detects in that paper what fatalists call a "trend of the times," a move towards a planned and deliberate central control by the State.

16. The Association believes that in so far as the State engages in the planning of health services it should plan a framework within which individuality and independence can flourish. The State should not seek to do for the people what they can do for themselves. It should not unnecessarily limit their freedom of choice or thought or action. It should do what is necessary, but refrain from the unnecessary. The State should spare from its bureaucratic attentions this form of human activity which, in an atmosphere of independence and freedom, has made more progress than it could possibly have made under the aegis of the State. The medical profession is not prepared to see itself converted into a branch of central or local government, or to become a "collectivized" unit within a free economy.

17. The Government's scheme is based on the principle that a comprehensive medical service should be available as a right, and irrespective of means, to all who want it, such service being paid for from insurance, taxation, and rates. The attitude of the profession is that the service should be available to all who need it, but that it is unnecessary for the State to make provision for those who are both willing or able, indeed prefer, to make it for themselves. Freedom is involved.

18. This is not merely or mainly a financial issue. It is true that under the Government's plan—the so-called 100% plan—private practice will be diminished, as will income from this source. This of itself may be a serious matter for some members of our profession. What is even more important is that a profession which derives its emoluments wholly or mainly from State resources is likely bit by bit to be controlled by the State which provides its emoluments. Here lies the greater danger both to the profession and to the public.

19. Until full details are known of the proposed administrative and professional arrangements and of the social security plan as a whole, and until more information is available as to the proposed machinery for safeguarding private practice among that section of the community which prefers it, the Association cannot commit itself to any acceptance of the 100% principle. Pending fuller information on these points, it reaffirms the wholly reasonable policy that the comprehensive service should be available to those who need it, and that the State should not make provision for those who are willing and able and anxious to provide for their medical service themselves.

### Principles

20. The Association approves the general principles set out in the White Paper, emphasizing that what is more important than their enunciation is their translation into action in the developments to come:—

(i) Freedom for people to use or not to use these facilities at their own wish; no compulsion into the new service, either for patient or for doctor.

(ii) Freedom for people to choose their own medical advisers.

(iii) Freedom for the doctor to pursue his professional methods in his own individual way.

(iv) The personal doctor-patient relationship to be preserved, and the whole service founded on the "family doctor" idea.

Some of the profession's more important criticisms of the White Paper proposals are set out below.

### SOME CRITICISMS

#### Central Administration

21. The central administration arrangements proposed are unsatisfactory. The Minister of Health and his Ministry are still left responsible for a number of functions only remotely associated with health. For example, the Ministry of Health is left responsible not only for such problems of housing

are clearly and closely related to health but for supervising the activities of local authorities in the actual construction of houses. Housing is an important factor in health (as are wage levels). Their design and siting approved, their construction is a matter for architects, builders, and engineers rather than for the Ministry of Health.

22. There is another disadvantage. Housing will be an acute post-war problem, and inevitably Ministers of Health will for some years be greatly preoccupied with its political and financial implications. Responsibility to Parliament for a health service should be sufficient to occupy the energies of any one Minister and his Department. It should not be allowed to become, for political or other reasons, a secondary or subsidiary responsibility.

23. Under the Government's proposals health responsibilities are to remain diffused among a number of different Government Departments including the Ministry of Health, the Board of Education, the Ministry of Labour, the Ministry of Pensions, the Post Office, and the Ministry of Fuel and Power.

24. One exclusion which the Government defends in the White Paper is scarcely justifiable—the exclusion of the industrial medical service. This is an employers' service, provided at the employers' expense. As a result it is common in the bigger and better factories, and much less common in the smaller works and factories where it is needed more. The factory is an important part of the worker's environment, and the medical supervision of the worker at the factory should therefore be linked with the supervision of his home environment, as part of the same health service. The industrial medical service is relatively new, and this linkage should be secured now. The Government's attitude in this is weak and illogical.

#### Central Health Services Council

25. Side by side with the Ministry of Health there is proposed an advisory body, the Central Health Services Council, to represent medical practice and medical teaching, hospital organization, and other professional interests—a body primarily medical. The proposal conforms to the pattern of advisory bodies set up in recent years. Many of these advisory bodies have proved useless because they have not been allowed to become useful. They have been façades to protect Ministers rather than committees to advise them. The Association cannot accept, as an appropriate advisory body to present and make effective medical opinion at the centre, one which is to be appointed by the Minister and to report only through him.

26. This, the usual, method is wholly inadequate in its application to medicine. If a medical (or mainly medical) body is to express the view of the medical profession on medical matters, it should, so far as its medical members are concerned, be appointed by the profession itself and not by the Minister. The hand-picking of such an advisory body would make it useless.

27. Further, in the field of expert medical advice, both Parliament and public should be entitled to know what advice has been tendered and whether it has been accepted or not. Only such safeguards will secure that medical advice is effectively given.

#### The Central Medical Board

28. The Association recognizes that in suggesting the Central Medical Board the Government intended to meet the known objection of general practitioners to enter into their contracts with local authorities. But the proposal to confer upon the Board two important powers has made this part of the White Paper a section to which the medical profession is most determinedly opposed.

29. The two powers are, first, the power to require practitioners intending to start afresh in public practice in any area to obtain in advance the approval of the Central Medical Board; and, secondly, the power to require newly qualified practitioners desiring to take up public practice in a particular area to enter the public service whole-time where considered necessary.

30. Both these powers can be used by "negative pressure" to direct practitioners as to where they will practise in the public service and the type of public practice in which they shall engage. However they are described, they are a form of civil

direction. The proposal to confer them is not made more attractive by the proposal that the Central Medical Board shall be composed mainly of doctors. The Association objects to their being conferred on *any* body—medical or lay or mixed. It recognizes that those who urge a planned economy for this country include as a part of their proposals some measures for the compulsory transfer of labour. The Board provides an illustration of the same trend of thought.

31. Errors of distribution of medical practitioners should be corrected by the process of attraction rather than that of compulsion. The Association is firmly opposed to the application of powers of compulsion either to doctors or to others. Indeed, they savour of a form of organization which this country has been exerting itself to oppose.

#### Local Organization

32. At the periphery the kind of organization suggested in the White Paper is even more chaotic than at the centre. There will be more, not fewer, local authorities. The new type of local authority proposed—the Joint Health Authority—is to be concerned with the planning and administration of hospital and allied services, and with the planning of non-hospital services. No steps are proposed to ensure that either these joint health authorities or their committees will contain persons of knowledge and experience in these subjects. The planning done, and the Minister's approval obtained, the non-institutional services are to be administered by other authorities, the existing major local authorities. Health functions will thus be distributed between more and not fewer local authorities.

33. Health Centres, if established, will be administered by County and County Borough Councils, and hospitals by joint health authorities. Ante-natal centres will be administered by one authority, the maternity hospital by another, while the control of the midwives' service may be vested in yet another. Responsibility for the control of infectious disease will be assigned to one authority, and the provision of infectious diseases hospitals to another. Ultimately school medical inspection may be the responsibility of one authority, and school medical treatment the responsibility of another. The general practitioner will be in contract with the Central Medical Board or both the Central Medical Board and a major local authority. The consultant will be in contract with the individual hospital authority. The public health officer will be in contract with his individual local authority. In brief, what is proposed is fragmentation, not unification, of medical services.

#### The Voluntary Hospital

34. The voluntary hospitals will, if the present proposals survive, be quietly but steadily submerged. Their contracts will be with exclusively local authority bodies which own the other type of hospital—the local authority hospital. They will receive less than the cost of the work they do, and be left to find the remainder in the atmosphere created by the Government "free for all" propaganda. Capital moneys are ignored.

35. The partnership between local authority and voluntary hospitals which the Government promised is to be achieved by virtually placing the voluntary hospitals under the control of the local authority "partner." They are afforded no effective place in the administrative or advisory machinery either at the centre or locally. Lip service is paid to these great institutions. What the White Paper proposals actually mean in practice is their elimination as autonomous organizations in a comparatively short time. These proposals would appear to illustrate once more the urge to control even a form of voluntary organization which, while uncontrolled, has achieved a magnificent standard of service to the community.

#### The Health Centre

36. Group practice, generally in Health Centres, is put forward in the White Paper as the basis of general practice development. The Government speaks of an experimental phase, but the arrangements proposed do not provide a proper basis for experiment. A joint health authority, after consulting the Local Health Services Council and taking or not taking its advice, may with the Minister's consent decide to embark on a scheme of health centres. Thereafter the County and

59. The terms and conditions of service of consultants should, like those of general practitioners, be negotiated centrally between the Minister and representatives of the medical profession. There is much to be said for placing the individual consultant or specialist in contractual relationship with the hospital or hospitals which appoint him, it being understood that the content of the contract is negotiated centrally. It has, however, the real disadvantage that general practitioners will look in one direction for contractual purposes, and consultants and specialists in another. Further consideration will need to be given to this point.

#### Private Practice

60. The future of private practice depends primarily on the proportion of the community to which this service is made available irrespective of means and as a right. The profession's present view on this issue has been stated earlier in this report. Before the profession can consider any modification on this attitude it needs fuller information on a number of points, including the general Social Security contributions, the administrative and professional arrangements, and the machinery for ensuring the continuance of private practice for those who desire to be treated privately.

61. In the case of general practice the points to be considered include the mode of distinguishing between Service patients and private patients, and the procedure to be adopted by citizens intending to utilize the Service for a particular item, or items, of medical service. In the case of consultant and specialist practice the profession needs fuller information as to the procedure proposed in the case of persons seeking consultative service in the consulting-rooms of consultants and specialists, and in private wards, wings, and blocks associated with general hospitals.

62. Whether or not the whole community is covered by this scheme, those who desire to obtain medical service privately should be absolutely free to do so from any doctor of their choice, and every practitioner should be free to render such service on a private basis with access to hospital facilities at every level, should such be necessary. This is an issue of the freedom of the public rather than of the interests of the profession.

## Appendix

### REPLIES BY THE MINISTER OF HEALTH TO QUESTIONS PUT TO HIM BY THE REPRESENTATIVE COMMITTEE

The Representative Committee submitted to the Minister of Health a series of questions on matters relating to the White Paper. The questions and the replies received are reproduced below.

#### Civil Rights of Doctors

**Question 1.**—*Can the profession be given an assurance that doctors who participate in the National Health Service will be allowed to retain as citizens their rights to serve as M.P.s and on local authorities and bodies concerned with the administration of the Service, and what steps will the Government take to protect these rights?*

**Answer.**—Yes. There will have to be exceptions, as there are now, like doctors employed in Government Departments and medical officers of health. But for the profession generally these rights must be fully retained. Any necessary provision to secure this will be included when legislation on the new service is put before Parliament.

#### 100% Issue

**Question 2.**—*Will the Minister give an assurance that the inclusion of 100% of the community in a National Health Service is contingent upon the inclusion of 100% in the national social security plan as a whole?*

**Answer.**—The proposals for the National Health Service were formulated on the assumption that there would also be proposals for a scheme of social insurance covering the whole

community. If for any reason this assumption were not realized the National Health Service proposals would be reconsidered in this respect.

#### Public and Private Practice

**Question 3.**—*By what machinery does the Government propose to make it possible for a general practitioner or a consultant to distinguish between a public patient and a private patient? Apart from the necessity for a general practitioner or a consultant being able to establish those cases in which a fee may be charged, the question is of importance in many different connexions—e.g.,*

(a) *If a patient chooses private institutional accommodation does he thereby relinquish his right to both treatment and accommodation under the public scheme in respect of the current illness? Will the patient be able to avail himself of the public service at any level of an illness and for any purpose, it being understood that in doing so he would have to change his doctor for that purpose—e.g., short-wave therapy?*

(b) *Can a patient be a private patient for general practitioner services and a public patient for consultant and/or hospital services, including radiological and pathological investigations and treatment, and vice versa? Can a general practitioner use public "investigation" services for a private patient?*

(c) *If, in spite of the Government's contract to provide all necessary treatment without charge, the particular service a patient needs is not available in his area under the public service but is available privately, what is the position as regards the payment of fees?*

**Answer.**—The Minister will particularly welcome the profession's help in working out the detailed problems of organization involved in this important group of questions. It seems to him that the general lines might be these:

(i) The general practitioner would treat as public patients any persons who had become his public patients through some suitable machinery to be devised (e.g., of a medical card signed by both doctor and patient.) He would treat as private patients, outside the arrangements of the service, any patients not so associated with him, whether or not they were associated with any other practitioner within the public service. There would need, of course, to be proper cover for people away from their home areas and similar cases, as now.

(ii) People would be entitled to take advantage of the public service at any time, and therefore to change at any time from being private patients to being public patients, either of the same doctor or of another—according to the ordinary process of choice and acceptance. If they thus became public patients of the same doctor, this would not affect any private liabilities incurred by them with him for any period while they were his private patients.

(iii) People would have the right to take advantage of part of the public service instead of the whole—e.g., a person who chose to be a private patient of a general practitioner would not thereby deprive himself of the benefits of the public service in a hospital, or of whatever domiciliary consultant services were made publicly available through the hospital service. Similarly a person who chose to be a public patient of a general practitioner would be free, if he wished, to obtain through that practitioner any specialist consultation privately and otherwise than through the public hospital and consultant services; and also, if he so wished to arrange privately for hospital accommodation and treatment outside the public service.

#### Comprehensiveness

**Question 4.**—*Why should not the scheme be really comprehensive in the sense that a single central authority should be responsible for the administration of all the civilian health services and only for those services?*

**Question 5.**—*What are the reasons for the exclusion of certain services from the scheme outlined in the White Paper—e.g., the industrial medical service?*

**Answer.**—The scheme is intended to provide for all necessary personal medical services. There are other services, con-

## MINISTER'S REPLIES TO QUESTIONS

MAY 13, 1944

nected with the work of other Government Departments, in the operations of which medical advice is constantly required but in which it plays a minor part. If medical advice is to play its full part in such services it must be constantly available and cannot be detached from the administrative framework of those other Departments without losing in force and availability. There is already liaison centrally, and this has become increasingly close in recent years. The White Paper gives the reasons for regarding the industrial medical service rather as a part of the general welfare service in industry than as a part of the personal medical services, and on page 10 reference is made to the importance of increasing use in this work of general practitioners who have received appropriate post-graduate training.

## Sufficiency of Personnel

**Question 6.**—How is it suggested that the number of doctors shall be increased so as to make the proposed service possible?

**Answer.**—It is fully realized that it would be difficult, if not impossible, to operate the new service under present wartime conditions of medical man-power, and that its operation will depend upon a substantial return of doctors from the Forces. But, when judged by more normal standards, there is no reliable means of assessing at this stage what increase, if any, in the supply of doctors will be necessitated by the new service. Particularly bearing in mind the many improvements proposed in regard to auxiliary services which will help to ease the demands on a doctor's time. The total number of doctors in this country has been for some time increasing at the rate of about 1,000 a year, and if the resources of the medical schools are enabled to be used to fullest capacity this rate of increase can be accelerated in the future. The Minister will want to discuss the question generally with the profession's representatives in due course. The recommendations of the Goodenough Committee will, no doubt, be relevant.

## Equality of Sexes

**Question 7.**—Will the Minister give an assurance that in the operation of the service there will be no discrimination between male and female practitioners?

**Answer.**—There is certainly no intention of discriminating between men and women doctors in the new service, apart from obvious kinds of special appointments which may require a woman rather than a man, or vice versa.

## Central Administration

**Question 8.**—What are the reasons why the service should not be administered as a "Corporation" (e.g., B.B.C. or P.L.A.), or as a council of the Privy Council (e.g., General Medical Council or Medical Research Council), or by a body similar to the Board of Admiralty, responsibility still lying through a Minister to Parliament?

**Answer.**—The reasons for vesting the ultimate central responsibility for the service in a Minister of the Crown, with the normal departmental machinery of central government, have been explained on pages 12 and 13 of the White Paper. It is not felt that there is any true analogy between the proposed new service and any of the services or activities with which the bodies mentioned in this question are concerned.

**Question 9.**—What are the Minister's objections to making the Central Health Services Council a body composed mainly of elected representatives—i.e., its medical membership being, in the main, elected, by the medical profession through its organizations?

**Question 10.**—What are the Minister's objections to the publication of reports by the medical group of the Council for the information of Parliament, the public, and the medical profession?

**Question 11.**—Is there any objection to the Council being given a secretariat independent of the Ministry?

**Answer.**—The Minister is anxious to consider in much more detail with the profession's representatives the whole question of consultative machinery, which is only roughly outlined in

the White Paper, and to the success of which he attaches the utmost importance. All the matters raised in these three questions will then need to be examined at some length, and it is impossible to cover the ground adequately in a short answer at this stage.

**Question 12.**—Will the Minister give some further reassurance and explanation with regard to the powers of the Central Medical Board, as the statements made by the Government spokesmen in Parliament have not removed the profession's apprehensions as to its powers of compulsion? The following are examples of the type of question being asked:

(a) If there were a shortage of public service practitioners in a particular area could not the deficiency be remedied by two or more part-time practitioners rather than by persuading or directing one practitioner to practise there whole-time in the public service?

(b) Is it not likely that the Central Medical Board will direct the flow of assistants to practitioners in full-time public service, and that practitioners doing some private practice will have difficulty in obtaining assistants?

(c) Is it the Government's intention that under certain circumstances a practitioner engaged in private practice shall not be able to accept and give treatment under public service conditions to any patient who wishes to receive it from him and to whom he is willing to give it?

**Answer.**—The proposal for a Central Medical Board is intended as a means whereby professional men and women, engaging themselves with the central government in future to take part in a service of general medical practice for the whole population, may be able to have direct contractual relations with a body which is itself predominantly professional. One reason for the proposal was that it was believed that many professional men and women would prefer such an arrangement to a contract either direct with a Government Department or with any local government organization. If this is not so, there are other possible alternatives which could be considered. It is probable, however, that it is not so much on the establishment of such a body, but more on the powers to be vested in it, that reassurance is sought in this question. In this connexion it is to be emphasized that there has never been any suggestion that the Board should have power to direct doctors to any particular area or to any particular engagements. Two powers are proposed in the White Paper in regard to the distribution of public medical practice:

(i) A power to refuse to admit additional doctors into the public service in a particular area if that area clearly does not need them. The machinery proposed for this is a requirement of the Board's consent when a doctor proposes to enter into a new public practice in which he has not been previously engaged.

(ii) A power in regard to new doctors starting in general practice for the first time; a power to say to such a new doctor that, if he wants to engage in the public service in a particular area which is in serious need of a doctor who will give all his time to public practice, then he can only engage himself there on that basis—for his first few years—although he can go elsewhere, of course, without giving all his time to public practice, or he can practise in the area privately.

On the particular aspects of the Board's powers which the question raises:

(a) If two or more part-time doctors were available and could remedy the deficiency equally well, then there would be no need to ask for the whole of the time of the young doctor who wanted to go there. That would be a question of fact in each case.

(b) It is difficult to see why a mainly professional Board should want to do this. But it is in any case a matter which could be corrected by general directions from the Minister, in consultation with the profession.

(c) It is intended that any practitioner shall have the normal right to participate in the service for all or part of his time, subject only to points (i) and (ii) mentioned above.

Generally, in regard to the proposed Central Medical Board and particularly in regard to the question of "over-doctored" and "under-doctored" areas, the Minister will welcome the profession's own ideas and suggestions and the opportunity of a more detailed discussion.

**Question 13.**—*What is the objection to securing a proper distribution of doctors by the attraction of elastic conditions of service and remuneration adaptable to different types of areas—e.g., Highlands and Islands Service?*

**Answer.**—It is recognized that there may be advantages in this for certain types of area if practicable methods can be devised. Any proposals from the profession will be carefully considered.

**Question 14.**—*Is it in the interests of the service that the general practitioner should be under central (or central and local) contract and consultants under local contract? Will this not split the profession?*

**Answer.**—It is believed that consultant services will best be based on the hospitals, and that the engagements of the consultants should therefore be with the hospitals concerned, voluntary or municipal. This is thought to be an arrangement which the consultants and the hospitals would on the whole prefer; but the whole consultant service arrangements have still to be discussed with the profession's representatives, and this point will not doubt be included in the discussion.

**Question 15.**—*What type of person are the part-time members of the Central Medical Board expected to be? Would they be medical practitioners spending the other part of their time in practice, or would they be civil servants?*

**Answer.**—The part-time medical members of the Board would be medical practitioners spending the other part of their time in practice.

**Question 16.**—*What influence is it expected the part-time members could have?*

**Answer.**—The part-time members would be the majority of the Board. A part-time basis is contemplated because it will secure that the Board is mainly composed of members who are themselves actively engaged in medical practice.

#### Local Administration

**Question 17.**—*How can there be comprehensiveness of local administration when the various services are distributed among several different authorities?*

**Answer.**—It is assumed that the question refers not to the "comprehensiveness" of the services given but to the "unification" of the means of giving them. It will be seen from the White Paper that the main key to that unification is in the arrangements for a single area plan, prepared locally by the joint authority with full professional guidance and approved centrally by the Minister, and covering the whole scope of the service for its area.

**Question 18.**—*What is to be the relationship of the environmental services to the curative services provided by the local authorities?*

**Answer.**—The importance of the environmental services is emphasized in pages 10 and 11 of the White Paper, where it is also made clear that responsibility for all these services is not included in the National Health Service organization, which is directed only to the medical and allied care of personal health. Responsibility for the wide variety of environmental services will continue to rest with whatever authorities are most appropriate to carry it in each case.

**Question 19.**—*How is it proposed to associate the general practitioner with work in the hospitals?*

**Answer.**—This is eminently a subject on which the profession's own views will be welcomed, both in planning the service and in subsequently operating it. It is impossible to deal with so important a question in a short answer. The arrangements in each area will rest on the area plan, worked out in consultation with the profession and requiring central approval. This

will be able to provide, as and where appropriate, for suitable "general practitioner" hospitals; but, quite apart from that particular kind of hospital provision, it must be recognized generally that it is in the best interests both of the public and of the medical profession that the general practitioner should have as many and as close contacts with hospitals as possible.

**Question 20.**—*What is to be the relation between general practitioners and medical officers of health?*

**Answer.**—The general practitioner, whether in separate practice or in a health centre, will not be under the direction or supervision of the medical officers of a local authority in the clinical pursuit of his professional work. It is important that he should have every opportunity of keeping in touch with the preventive work of the medical officers of health, and it is the intention that the services of the general practitioner should be used increasingly as time goes on in the performance of functions which have hitherto been mainly the concern of separate whole-time clinics.

**Question 21.**—*Into how many joint board areas is it proposed to divide the country?*

**Answer.**—No proposals as to the actual areas are yet under consideration. These can only be settled after consultation with the organizations and interests concerned.

**Question 22.**—*What is the objection to vocational, including medical, representation on joint health authorities?*

**Question 23.**—*Is it contemplated that joint health authorities should be required to establish committees to which definite functions are referred? If so, is vocational representation on these bodies contemplated?*

**Question 24.**—*Will the Minister give an assurance that voluntary hospitals shall be represented on the joint board authorities?*

**Answer.**—In the White Paper it was recognized that there are arguments for and against including on the local administrative authorities, or on their various committees, a proportion of non-elected members to represent professional organizations and the expert point of view. On balance, it was felt that the risk of impairing the principle of public responsibility lying with the elected representatives of the people outweighed any advantages which were likely to accrue. The Minister will be glad, however, to consider carefully any proposals which the profession has to offer that will not conflict with this principle of democratic responsibility.

**Question 25.**—*What type of experience will be expected of the medical advisers, if any, of the new joint authorities?*

**Answer.**—It is anticipated that the new joint authorities will need—for their varied and important functions—not only full-time officers of high calibre but also part-time advisers in specialist and general practice. In addition they will have the regular advice and guidance of the Local Health Services Councils. It is probably the senior full-time officers that the question has most in view. Recruitment to such posts should clearly not be restricted to any particular group or class of doctor, but should be open to the most suitable person in each case, whatever the source from which he or she is recruited. Experience in medical administration, hospital organization, or public health will obviously be relevant qualifications, and there is scope for further development in training and postgraduate education in these fields.

**Question 26.**—*Will the Minister describe the structure and functions of the local bodies referred to on page 29, paragraph (2)?*

**Answer.**—The profession's own views are wanted before the exact constitution of these bodies can be settled. The intention of the White Paper was that they should perform on the spot the kind of duties at present performed by the Insurance Committees, and thus avoid overburdening the central organization of the Central Medical Board with functions in relation to the general practitioners which experience has shown can be locally discharged.

## Hospital Services

**Question 27.**—*What is the objection to voluntary hospitals being paid in full for the services they render under the scheme?*

**Answer.**—If the whole of the cost of the whole of the public service rendered by the voluntary hospitals—i.e., all their services other than to private paying patients—were paid from public funds, the hospitals would have a less obvious claim to voluntary financial support from the public, and the voluntary hospital movement as it is now known would be endangered. It is neither the wish of the Government to see this happen nor their belief that the public wants it to happen. At the same time, while this principle seems important in the interests of the voluntary hospital movement, the financial arrangements must be such as will ensure that the hospitals can efficiently perform the services asked of them. The exact arrangements needed to ensure this will be fully worked out in consultation with the hospitals' representatives as soon as possible.

**Question 28.**—*Will there be any Exchequer grant for a voluntary hospital in order to enable it to carry out extensions necessary to provide an adequate local service as part of a joint board scheme? Or is such financial assistance to be provided entirely by or through the joint board?*

**Answer.**—This was not dealt with in the White Paper because there had been no preliminary discussions on the point with the hospitals' representatives. It is a point of obvious importance which will be discussed with them as soon as possible.

## Consultant and Specialist Services

**Question 29.**—*Is there to be free choice of consultant by general practitioner? If so, can the consultant be appropriately paid by salary for this part of his work?*

**Answer.**—The intention is that the approved area plan will determine generally the hospitals or groups of hospitals and the specialists to which particular classes of case should be referred within the public service, but within the general arrangements so determined as much free choice as possible will be maintained. It is proposed in the White Paper that the specialists taking part, whole-time or part-time, shall be based for their public service activities on the various hospitals in the way which the plan provides, and they will look to the hospitals concerned for their remuneration; but methods and details of remuneration remain to be discussed.

**Question 30.**—*Will the Minister give an assurance that the personal relationship between general practitioner and consultant shall be preserved?*

**Answer.**—It is the intention that a close personal relationship shall be assured between the general practitioners and the specialists to whom they will refer their patients within the arrangements of the area plan.

**Question 31.**—*What is to be the machinery for the provision of domiciliary consultations? Will the Minister amplify the passage on page 25 of the White Paper: "And—for certain consultants as circumstances may require—of visiting Health Centres and clinics, and, in case of need, the patient's home, at the request of the general practitioner?"*

**Answer.**—It is contemplated that the arrangements of each area plan for providing consultant services should include arrangements whereby consultants will undertake any necessary visiting of patients in their homes at the request of the general practitioner. Which of the available consultants undertake this function will be a matter for local arrangement with the hospitals within the area plan and, of course, with the individual consultants themselves.

**Question 32.**—*Are the details of remuneration for both consultants and specialists to be arranged centrally? On page 25 of the White Paper it is stated that "some central regulation of scales will be required." If all conditions of service for consultants and specialists are not to be arranged centrally what machinery is proposed?*

**Answer.**—No proposals on this have yet been formulated. But it appears likely that standards of remuneration will need to be settled centrally, in consultation with those concerned, and then prescribed for observance by all hospitals within the service.

## General Practitioner Services

**Question 33.**—*Does the Minister agree that the limited compensation proposals set out in the White Paper raise the whole question of compensation for loss of capital value of all general practitioners? What is the attitude of the Minister to this question?*

**Answer.**—Questions of compensation, of the possibility of providing a superannuation system, and of the desirability—and practicability—of discontinuing in future the sale and purchase of practices in the public service, all need to be considered together. The Minister hopes that the profession's representatives will join him in a general discussion of all these issues before the legislative stage arrives, and in this discussion he will particularly welcome the profession's own suggestions.

**Question 34.**—*Why should the Health Centres not be in the same relationship to the joint authorities as the hospitals?*

**Answer.**—The proposed demarcation of functions between the major local authorities acting on their own and the same authorities acting in combination over wider areas is, broadly, that services which belong to the sphere of the hospital, the specialist, and the consultant, and which therefore need to be planned and administered over larger areas, should rest with the combined authorities, while services which do not should rest with the single authorities. On this basis the provision of Health Centres falls into the latter group.

**Question 35.**—*What will be the administrative effect of a Health Centre being attached to a hospital, the hospital being under the joint board, and the Health Centre under the individual local authority, the participating practitioners being also under contract with the Central Medical Board?*

**Answer.**—In practice this situation, where it arises, should not create any serious administrative difficulty. Financial adjustments between authorities which share the same premises for their services have in the past proved perfectly feasible. Whatever the local authority organization, a similar question would arise anyway where a Health Centre was attached to a voluntary hospital. The position of the general practitioner would not seem to be affected by the fact that a particular Health Centre was attached to a hospital.

**Question 36.**—*Will the Minister give an assurance that experiments will be made in Health Centres of varied types and functions under medical guidance before central policy is adopted, and that an experimental centre shall be set up only with the acquiescence and full co-operation of the local profession?*

**Answer.**—It is fully intended to make experiments in Health Centres of varied types and functions in varied kinds of areas, and to do this with the guidance of the medical profession through both the Central and the Local Health Services Councils. As stated in the White Paper, the wish of the local doctors to bring their work into the centres must obviously be a big factor in decisions to provide centres.

**Question 37.**—*Will the Minister give an assurance that experimental Health Centres shall be available to all the practitioners in the area?*

**Answer.**—No assurance can be given that at any particular time there will be enough Health Centres available for all doctors who desire to enter that form of practice. But the desire of doctors to do so, if backed by the success of the Health Centre experiment, would be an important reason for hastening developments in any area. So far as the question may relate only to special diagnostic or similar facilities set up for an area, it will obviously be desirable to make these as widely available as possible to all doctors locally engaged in the public service.

**Question 38.**—Does the principle of free choice and the preservation of the doctor-patient relationship include free choice of patient by doctors working in Health Centres, subject to the limitation of lists? If so, what machinery is proposed to enable a doctor to obtain the transfer of a patient from his list when he feels that the association is no longer beneficial?

**Answer.**—Yes. It is not proposed that doctors in Health Centres should be placed in any worse position in this respect than doctors in public practice outside Health Centres. Details of machinery remain to be discussed.

**Question 39.**—Will the Minister give an assurance that patients will be allowed a reasonable choice of Health Centre if and when established, and that this choice shall not be unnecessarily limited in the case of patients living near the boundary between two local authority areas?

**Answer.**—Yes. Every endeavour will be made to secure this.

**Question 40.**—Why is remuneration by salary considered necessary for practitioners working in Health Centres? In other words, why is competition considered to be incompatible with Health Centre practice?

**Question 41.**—What is meant by salary or "similar" method of remuneration (p. 32)?

**Answer.**—This subject is dealt with on pages 31-2 of the White Paper. The phrase "similar method" is meant to cover any reasonable and practicable method of remuneration which is in accord with the conception of partnership between doctors working together in a Health Centre. A possible example is a small basic salary for all, plus a pooling of the allocatable income of the centre and a sharing among its doctors on an agreed partnership basis. There are other possibilities, no doubt. Suggestions from the profession on this will be welcomed.

#### Maternity Services

**Question 42.**—Will every woman be entitled to the attendance of a doctor of her choice under the service throughout the ante-natal, natal, and post-natal stages of maternity?

**Answer.**—This is one of the questions which the Minister particularly wishes to discuss in more detail with the profession before any proposals can be formulated. The main problems will be to determine the extent to which a woman should have a right to require her family doctor under the new service (or any other doctor) to be present at her actual confinement, how far it should rest only with the midwife to call in the doctor if needed, and in that event whether it should normally be the woman's family doctor who is called in.

#### Medical Officers of Health

**Question 43.**—How is it proposed to compensate a medical officer of health for the loss of the intellectual satisfaction to be derived from the varied work for which he is at present responsible when he becomes a subordinate officer in a larger authority or remains the officer of an authority shorn of the functions which have been his main interest for many years?

**Answer.**—The underlying assumption of this question cannot be accepted. A service of the kind and the scope now proposed will clearly increase, rather than restrict, the field of interest and activity in this branch of professional life.

**Question 44.**—Are the salaries of medical officers of health to be left to voluntary agreement, while the rates of remuneration of general practitioners and perhaps of specialists are wholly or largely settled by central agreement for the whole country?

**Answer.**—This is a matter which must be discussed before the new arrangements are settled. Already there is some element of central standardizing of scales for this branch of the profession, and the review of these scales will need to be considered in any case.

A. V. S. Sarma (*J. Ind. med. Soc.* 1043, 13, 74) records his observations on 25 cases of typhoid fever treated with nicotinic acid, and found that it was devoid of any toxic effect. When used early in the disease it appeared to be particularly beneficial in combating oro-lingual ulceration, excessive salivation, mental symptoms such as confusion and delirium and insomnia, and in reducing length of stay in hospital.

## HEAD INJURIES INVOLVING AIR SINUSES

BY

DONALD MCKENZIE, F.R.C.S.

Major, N.Z.M.C.; Officer in Charge of Base Neurosurgical Unit for Middle East

This paper aims at recording the details and the experience gained of 10 such cases of head injury treated by operation in the neurosurgical unit. Publication of these cases was stimulated by reading a paper on this subject by C. A. Calvert (1942) from the Military Hospital for Head Injuries, and this series lends point to his plea for early operation. Hitherto the tendency has been to adopt an expectant attitude, and, if the rhinorrhoea stops in a few days, as it may easily do, then to do nothing more. In the pre-sulphanilamide days I had the tragic experience of losing such a patient with pneumococcal meningitis in the sixth week, and other cases quoted in the paper referred to show that the danger exists for as many years after injury. In all the cases the anterior fossa was involved, and these observations concern the sinuses of that region and do not include the mastoid sinus.

**Anatomy.**—The regions which are fraught with the danger of a compound fracture into the subarachnoid space are the posterior wall of the frontal sinus, the ethmoid cells, the cribriform plate itself, and the sphenoidal sinus. The dura may be penetrated by a spicule of fractured bone in any situation, but the floor of the anterior fossa lends itself to an additional method of damaging the dura. The bone in the region specified is extremely thin—even of tissue-paper thinness in places—and the closely attached dura is also very thin. When the base of the skull is fractured either by radiation from the vertex or by general distortion, the dura splits easily in this situation. On several occasions one edge of a dural tear has been removed from a linear fissure which has ripped the dura. Hence in the anterior fossa base the thin dura may be penetrated by spicules or split by distortion accompanying a fissured fracture. A distinction must be made between trauma of the ethmoid region and that of the cribriform plate. In the former region the fracture must tear the dura, but, in the latter, rupture of the olfactory nerves alone leaves an open pathway to infection. The sphenoidal sinus is least likely to be involved, as most fractures are anterior to this region.

**Material.**—Four of the 10 cases were battle casualties and 6 were due to blunt injury.

#### Case Histories

**Case 1.**—A cannon-shell splinter penetrated this man's forehead on Nov. 11, 1942, and radiographs showed the track passing via the left frontal sinus, right ethanoids, and right antrum to the right temporal fossa. Rhinorrhoea was noticed a few days after injury, and it persisted irregularly in time and amount. Operation on March 8 (4 months after injury) showed a fistula running through a hole 1 in. by 1/4 in. in the posterior wall of the left frontal sinus and the anterior cribriform plate. Nasal mucosa was visible through the latter. A graft of fascia lata was applied over the opening remaining when the fistulous track was divided. The whole region was powdered with sulphathiazole and the wound closed.

**Case 2.**—This man had lost both eyeballs on March 27, 1943, from a shell splinter. Cerebrospinal fluid was seen to leak from the left nostril on March 30. With jugular compression later, cerebrospinal fluid ran from the right orbit. X-ray report: "Extensive damage to facial bones, left zygoma, left malar, bridge of nose, and fracture of posterior wall of right frontal sinus." Operation on April 12 (16 days after injury) showed a crack of the posterior wall of the right frontal sinus running into the cribriform plate, and C.S.F. gushed out on raising the dura from this crack. A similar vertical crack on the left side ended in a loose piece of bone posteriorly. Dura from both sides of the cribriform plate was stripped back, enabling a large graft of fascia lata to be applied over the whole area after the crista galli had been removed.

**Case 3.**—This soldier was wounded on March 22, 1943, by a mortar splinter in the forehead, which also destroyed the right eye. He had a mild attack of meningitis on April 16; and on May 7 for the first time a severe leakage of C.S.F. was reported, and 5 c.cm. was collected rapidly from the left nostril on that day. X-ray report: "A large right frontal bone defect with many fragments in the orbit, but none in-driven." Later films showed a fine linear fracture running vertically down in the midline and crossing to the left side as it approached the cribriform plate. Operation on May 8 (47 days after injury) revealed a track passing from the right frontal lobe to the open cavity of the frontal sinus. The cribriform plate was intact on both right and left sides. In this case alone the dura was

pened, the adherent tip of the frontal lobe was amputated and a graft of fascia lata applied inside the dura over the opening, and the dural incision was then closed.

**Case 4.**—This man was injured by a mine on Dec. 18, 1942. Brownish rhinorrhoea was observed two days later and continued until Feb. 26, 1943, after which there was never enough C.S.F. to collect, though it was thought to be present. X-ray report: "Extensive damage of the left frontal bone, nasal bones, and left anterior fossa. The fracture passes back in the floor of the left anterior fossa." Encephalography on Feb. 11 showed no abnormality. Operation on June 17 (6 months after injury) revealed two vertical cracks in the left frontal sinus and one crack in the right frontal sinus running down to a large hole in the posterior wall. A tear in the dura opposite the hole on the right side was sutured with black silk, the crista galli was removed, and a flap of temporal fascia was placed over the area.

**Case 5.**—This man crashed on a motor-cycle on May 13, 1943. There was no history of C.S.F. leak. Proptosis was present, and vertical diplopia, due to the depression of the orbital roof and eyeball on the right side to about 1 in. depth. X-ray report: "There is a circular fracture involving the right frontal bone down the midline through the frontal sinus (both anterior and posterior walls affected), across the right cribriform plate and orbital roof out to the temporal fossa, and up towards the vertex to join the fracture of the forehead, completing the circle. There are other secondary fractures, and the orbital roof is a pulped mass depressed into the orbit." On July 13 (2 months later) operation was undertaken to raise the orbital roof and permit the eyeball to be raised, and also to explore the dura. A large hole was found in the posterior wall of the right frontal sinus. The right orbital roof and supraorbital crest were in pieces and were raised to their normal position. A doubtful minute hole in the dura towards the front of the cribriform plate had a small muscle-graft placed over it. Convalescence was uneventful. The left eyeball began to rise steadily in the orbit, the diplopia lessened, and the ophthalmologist advised that no further operation on the eyeball itself was necessary.

**Case 6.**—This man was hit on the nose by the breech-block of an anti-aircraft gun on May 28, 1943, fracturing the nasal bone. C.S.F. rhinorrhoea was reported on the third day and lasted for several days. He developed five recurrent attacks of pneumococcal meningitis, each attack being controlled by sulphadiazine or sulphathiazole, until eventually he was flown to this unit on July 5. He was in coma in two of these attacks, and the pneumococcus was cultured from the C.S.F. on one occasion. He developed another attack on the day after admission. X-ray report: "A fine linear fracture of the posterior wall of the left frontal sinus running back towards the cribriform plate." Operation was undertaken on July 10, this last attack of meningitis settling down in four days. A crack was found on the left side as shown in the x-ray film, running down to the midline and across, to end in a small hole on the right side of the cribriform plate, where mucus could be seen in the nose. The dural tear was increased in stripping the dura back off the cribriform plate. The dural tears were sutured with black silk before placing a large graft of fascia over both sides. He was out of bed on the thirteenth day, but developed a mild meningitis attack next day. This cleared up rapidly with sulphadiazine therapy, and there were no further complications. He was quite well when seen in late November.

**Case 7.**—This man sustained a motor-cycle crash on June 1, 1943, and was operated upon at once in another hospital. Spicules of bone were picked out of the dura, and C.S.F. leak was reported for three days after operation. X-ray report: "A long linear gap in the left frontal bone—the frontal sinus opened and several fragments of bone are situated behind the gap, but not necessarily intracranial in position." Operation on July 12 (6 weeks after injury) revealed a hole in the posterior wall of the left frontal sinus. On this side a protruding bone fragment 3 by 1.5 cm. was drawn out from a dural perforation. A crack was found on the right side anterior to the cribriform plate, with adherent dura. On removing this dura C.S.F. ran out. The dural holes were sutured and a graft of temporal fascia applied over the whole area.

**Case 8.**—This man was injured in an aeroplane crash in 1943. Two lacerations in the forehead had been sutured, but they were infected and both eyes were closed by oedema. A constant discharge of brownish C.S.F. came from the left nostril. Spinal puncture revealed deeply blood-stained fluid. X-ray report: "There is a depressed fracture of the right frontal bone into the frontal sinus with comminution of the orbital roof and ethmoids. A fracture can be traced down through the ethmoids into the maxilla." Operation performed 2 days later revealed a loose piece of bone in the posterior wall of the right frontal sinus continuous with the crista galli, which was also fractured. The crista galli and attached sinus wall were removed. There was a small dural tear opposite the crista, and the right orbital plate and ethmoid roof were cracked in many places. A temporal fascia graft was applied over the small dural tear. The supraorbital crest was raised into position and the

depressed frontal bone was also elevated. Convalescence was uneventful.

**Case 9.**—This officer crashed on a motor-cycle on Aug. 13, 1943, and it is probable that the wheel of the oncoming truck went over his head. He reports that C.S.F. leaked from the nose on the second day and continued for several days. There was a right sphenoidal fissure syndrome—i.e., partial loss of the first to sixth cranial nerves. X-ray report: "A gross 'block' fracture of the facial bones—the upper limit passing through both fronto-malar areas and roof of the nose to both sides of the cranium, and the lower limit passing through the body of the maxilla, involving both antra." Operation on Aug. 27 (14 days later) explored both sides of the anterior fossa back to the transverse fissured fracture, which was just anterior to both sphenoidal crests. A subsidiary crack into the right ethmoid region was found, with a dural tear in apposition. The optic foramen was laid open and the sphenoidal crest was also removed to leave the optic nerve theca and the sphenoidal fissure exposed. There was a small tear in the optic nerve theca, through which a normal optic nerve could be seen; no blood-clot was present. A graft of fascia lata was applied over the dural tears. Post-operatively he was thought to be developing a frontal lobe abscess, but the appearance of paraesthesia, sensory changes, and muscle weakness in the palate, neck, and limb muscles established a diagnosis of peripheral neuritis. He was seen in December, when the loss of the lower half of the right field of vision was the only remaining sign of the previous paralysis of the first six cranial nerves on the right side. There was still some weakness in the left leg muscles.

**Case 10.**—This man was injured on Aug. 27, 1943, in a car smash, and there were compound fractures of a forearm and a leg in addition to the severe head injury. C.S.F. rhinorrhoea was free from the right nostril for five days, and irregularly after that. X-ray report: "There is a depressed fracture of the fronto-nasal region, with extensions on both sides to the ethmoid plate. The frontal sinuses are involved in the fracture." Operation on Sept. 13 (17 days later) revealed a loose piece of bone in the posterior wall of the left frontal sinus attached to the fractured crista galli. There was a small dural tear on both sides of the crista due to penetration of spicules. The dura was cleared well back on the cribriform plate to enable these holes to be pursestrung with silk, and a graft of fascia lata was superimposed.

### Diagnosis

C.S.F. rhinorrhoea and intracranial aerocele are two indubitable signs that the dura has been torn and that meningitis may be imminent. Aerocele did not occur in any of the 10 cases, but its presence demands investigation and operative repair of the dural injury.

**C.S.F. Rhinorrhoea.**—In this series the discharge was slight, lasting two days in three cases, three days in two cases, and irregularly for weeks in three cases; in only one case was there a profuse discharge, whereby 5 c.cm. of fluid was collected easily on the 46th day. In five cases the onset was delayed several days, presumably until the shrinkage of obstructing blood-clots permitted the fluid to escape. In the one case with profuse rhinorrhoea the discharge did not appear until the 46th day. In the first few days after injury the C.S.F. may be deeply blood-stained from associated cerebral laceration, and any early nasal bleeding should be given careful consideration. Case 6 showed blood-stained fluid, and Cases 4 and 8 a brownish discharge. Localization of the fracture to the same side as the rhinorrhoea has proved to be quite unreliable unless taken in conjunction with the homolateral anosmia and corroborative x-ray findings. Cases 2, 3, and 8 showed left rhinorrhoea, but the dural tear was right-sided; and Case 10, with right rhinorrhoea, had bilateral dural tears. Nasal mucus, or tears, may cause doubt when the amount of fluid is scanty; but jugular compression will usually increase the flow, and the presence of sugar will establish the nature of the fluid.

**Anosmia.**—Though not an outstanding symptom, anosmia is valuable evidence of local injury where it can be established that there has been an alteration in the sensation of smell following the injury. The patient may be too comatose to examine or to give his pre-traumatic condition. Also, one or both nostrils may be blocked by swelling. In our cases the man's statement about his previous sense of smell was accepted. Three cases had no sense of smell on either side; two had a slight degree of smell on one or both sides; four had anosmia on the appropriate side; and the one case with no dural tear had normal sensation.

**Radiography.**—The recognition of a fracture in the floor of the anterior fossa may be an extremely difficult matter. In Case 6 a faint vertical crack was visible in the posterior wall of the sinus, but it could only be surmised that it continued back into the cribriform plate. At operation it was demonstrated that it had crossed the midline and ended in a hole on the opposite side. Case 5 was described as a circular fracture, but it was also surmised that the fracture crossed the orbital and cribriform plates, whereas it could be easily traced up from the temporal fossa across the forehead and down through the frontal sinus. Our procedure was to take stereo-

scopic antero-posterior and lateral views and then, if necessary, oblique views. Posterior fractures involving the anterior clinoid process may be elucidated by taking an axial view of the optic foramen where the outer boundary is formed by the anterior clinoid process. Cases 9 and 10 were of the type described as a "block" fracture. The central naso-frontal block of bone was detached by two lateral fissures through the ethmoids in the one case and through the temporal and frontal bones in the other.

**Spinal Puncture.**—I believe that all patients with a head injury should have a spinal puncture. In the case of these anterior fossa fractures, examination of the spinal fluid may give warning of meningitis, and also it will check the presence of blood if there has been any doubtful nose-bleeding.

**Meningitis.**—Meningitis itself may confirm the diagnosis. Case 6 showed no fracture in the original films, but the history of five recurrent attacks of pneumococcal meningitis was accepted as confirmation of a dural tear, and a stereoscopic film revealed a hairline crack in the frontal sinus. Case 3 developed mild meningitis—headache, neck rigidity, pyrexia, and 10 cells per c.mm.—on the 25th day after injury. This was controlled in a few days by sulphadiazine therapy. On the 46th day he complained of a "running cold in the head," and was observed to have a profuse C.S.F. rhinorrhoea. It may be mentioned, by the way, that, though frank meningitis is diagnosed clinically by delirium, pyrexia, neck rigidity, and spinal fluid containing several thousand cells per c.mm., I cannot remember a case in which an organism could be recovered from the spinal fluid after sulphadiazine therapy had been instituted.

### Treatment

All of these 10 cases were seen some time after their original injury, when they were co-operative and could be investigated fully. There should be no urgency in operating on a recently injured head case until the patient has recovered from the cerebral trauma; and, in fact, judged by this series, the diagnosis of a torn dura would not be made for several days or weeks.

**Preliminary Treatment.**—All cases received prophylactic sulphadiazine—preferably by mouth, but intravenously if necessary. The dosage was 6 g. daily, but if meningitis was present this was increased to 12 g. daily and an initial 6 g. given intravenously. Blood transfusion was rarely necessary, as the operation does not produce shock and was usually completed in two hours.

**Anaesthesia.**—This was essentially local infiltration of 0.5% novocain solution after a preliminary hyoscine and morphine injection, which was supplemented by intravenous pentothal drip when necessary. Our procedure was to set up an intravenous saline drip apparatus at the start, and then either blood or pentothal could be rapidly substituted.

**Operative Technique.**—A coronal incision within the hair line was used in most cases, turning the forehead flap down to expose both supraorbital ridges. In one case only a linear midline scar already present was incised to turn a unilateral flap, but the cosmetic effect of the coronal flap is well worth achieving at the expense of a bigger incision. The bone flap was unilateral or bilateral, dependent on our confidence in the localization of the dural injury. In either case it was hinged on the temporal muscle, and was made with four burr-holes for the unilateral flap and six burr-holes if bilateral. The lower midline burr-hole was placed as low as possible after studying the size of the frontal sinus. Five cases had bilateral bone flaps, and in only one case was there any bleeding from the longitudinal sinus. The dura was stripped up off the orbital plate both medially towards the cribriform plate and posteriorly towards the sphenoidal crest. Any fracture was easily seen, and the dural tear or escape of C.S.F. was looked for on the opposing dural surface. The opposite side was explored similarly. The more difficult case was the fracture of the crista galli or cribriform plate, where, to get at the dural tear adequately, the dura had to be stripped out of the elcft beside the crista galli—a very difficult procedure. The dura could then be stripped back easily to the sella turcica region if necessary. This complete elevation on both sides was necessary in only two cases (Case 6 and Case 10). It allowed the dural holes to be pursestrung with fine silk, and gave a very good exposure, but is best avoided if any smell sensation is still present. Our procedure was then to powder the dura with sulphathiazole, apply a fascial graft over the area like a postage stamp, and seal an edge with diathermy. The crista galli was nibbled away before applying a midline graft, which would be distorted by its presence. Fascia lata was employed in six cases in which a good solid graft was indicated. Temporal muscle fascia was used in three cases, but it is thin and no great area can be covered. A muscle-graft was used in Case 5, where there was a minute and dubious hole. The graft was applied extradurally except in Case 3, in which the dura was opened widely to permit removal of the adherent anterior lobe. In this case it was much easier to apply the graft intradurally. It is reasonable to suppose that some other cases could be grafted more simply by working intradurally and avoiding a wide elevation of the dura. But the dural tears are small, and are best located by finding

the fracture and then seeing the hole or the escaping C.S.F. in the region. I do not think these small dural tears could be located well intradurally, and also there is an advantage in avoiding trauma from direct handling of the cerebral lobes.

All bleeding was stopped by diathermy to the dural veins wax to the bone. It is much more important to have the dural bleeding completely stopped in these low-pressure cases than in tumour operation, in which the raised pressure will stop any extradural oozing. The whole dura was then powdered and the flap and scalp sutured in place in the usual way. Bone chips were employed to fill up the frontal burr-holes.

**After-treatment.**—No special complication arose. Both eyes were usually closed by frontal oedema for one or two days. Sulphadiazine therapy was continued for five days after operation with the routine dosage of 6 g. daily. These patients had little pain, and some wished to be allowed up on the third day, though this was not permitted until the tenth day. When revisiting the unit on Nov. 12 all patients had been discharged and were understood to be well.

Those patients with complete anosmia did not appear to mind their disability. They could not detect any testing materials in the mouth or nose, though taste was unimpaired. One patient (Case 7) had a constant subjective sensation which he described as a "disinfectant" smell.

### Conclusions

The following are the conclusions arrived at: (1) That the dangers associated with C.S.F. rhinorrhoea need stressing to medical officers. (2) That unless the possibility of dural tearing is kept in mind, the rhinorrhoea, anosmia, and radiological evidence of fracture may be easily overlooked. (3) That every head injury with C.S.F. rhinorrhoea, however slight, should undergo operative repair of the dura rather than risk the vagaries of natural repair. (4) That with the technique used the operation is neither formidable nor dangerous; there were no deaths and no complications in this series.

I wish to thank the War Office for permission to publish this paper, and also my colleagues Lieut.-Col. R. R. Lumsden, E.N.T. Specialist, Major W. H. Milligan, Radiologist, Major J. E. Caughey, Neurologist, and Major H. B. Stallard, Ophthalmologist, for their helpful collaboration in the care of these patients.

## USE OF CRUDE PENICILLIUM FILTRATE FOR LOCAL TREATMENT

BY

J. M. ALSTON, M.B., M.R.C.P.Ed.  
(Archway Hospital, London)

The therapeutic value of partially purified penicillin has been established in this country (Florey and Florey, 1943; Fleming, 1943; Report to War Office, 1943; Christie and Garrod, and others, 1944) and in the United States (Keefer et al., 1943), but the use of untreated filtrate of cultures of *Penicillium notatum* has been very little noticed, although successful results have been obtained with gauze impregnated with the living mould (Hobson and Galloway, 1944):

This communication gives the results of the local use of the untreated filtrate in 24 patients. The strain of *P. notatum* was kindly given by Prof. Fleming, and in growing it for this purpose the medium has been changed from time to time but has always been a modification of the Czapek-Dox formula. At present it is made according to that of Challinor and MacNaughtan (1943) without the yeast extract which they recommend and with the addition of calcium carbonate. The following constituents are dissolved in a litre of distilled water:

Sodium nitrate (NaNO <sub>3</sub> )	.. .. .	3.0	gramme
Potassium chloride (KCl)	.. .. .	0.5	"
Magnesium sulphate (MgSO <sub>4</sub> , 7H <sub>2</sub> O)	.. .. .	0.5	"
Ferrous sulphate (FeSO <sub>4</sub> , 7H <sub>2</sub> O)	.. .. .	0.01	"
Potassium dihydrogen phosphate (KH <sub>2</sub> PO <sub>4</sub> )	.. .. .	6.5	"
Disodium hydrogen phosphate (Na <sub>2</sub> HPO <sub>4</sub> , 12H <sub>2</sub> O)	.. .. .	33.5	"
Glucose (pure B.D.H. anhydrous or "Climax" brand, Corn Products Ltd.)	.. .. .	40.0	"
Distilled water to 1,000 c.cm.			

Sterilize in free steam for 1½ hours in 200-c.cm. amounts in 1-litre conical flasks. Add 5 c.cm. of 10% solution of sterile calcium carbonate to every 200 c.cm. of medium before inoculating. The final pH is about 7.

The medium should form a depth of not more than 1.5 to 2 cm. in order to expose to air a large surface relative to the volume. Incubation is at a temperature of 24°C. for 8 to 10 days. When the flasks have not been shaken the mould forms a thick firm pellicle and the culture medium below is almost as clear as before incubation. The fluid medium, after growth, is passed through a Seitz filter, and is tested to make sure that the reaction is nearly neutral and that less than 0.1% glucose is left.

The assay of the product is made by comparing its action on the Oxford strain of staphylococcus with the action of a standard specimen of calcium salt of penicillin. The method mostly used is the established one of measuring the zone of inhibition of the staphylococcus around a piece of porcelain tube (containing the penicillin) set on a heavily inoculated plate of agar medium, and, occasionally for check, the assay is made by inhibition of the growth of the coccus in broth produced by serial dilutions of the standard preparation and the unknown filtrate (M.R.C. War Memorandum No. 12). The filtrates used for treatment varied in strength from 4 to 10 units per c.c.m.; they do not lose strength when kept at 4°C. for seven days nor when heated to 65°C. for 24 hours. More details of the methods used for production and assay are described in a paper by R. M. Sandercott, which is expected to appear in the *Bulletin of the Institute of Medical Laboratory Technology* in July of this year.

Specimens of pus, etc., from patients for whom penicillin treatment was desired have in most cases been cultured bacteriologically, and the most important pathogens (usually staphylococcus or haemolytic streptococcus) tested for sensitivity to penicillin.

The filtrate is applied to superficial lesions by gauze soaked in it, by a cream (made of lanette wax 4%, liquid paraffin 25%, paraffin wax 3%, and filtrate 68%) or by portions of the recently grown mould after the fluid medium had been drained away from it. Cavities in bone which are accessible to the surface are packed lightly with gauze soaked in the filtrate and sealed (if surrounding surfaces are suitable) with sheets of "cellophane" fixed by elastoplast. Deep sinuses in muscle and subcutaneous tissues are treated with indwelling catheters, which are carefully shortened as the sinuses heal from the bottom. Cavities and sinuses are washed out with saline before fresh filtrate is left in them. Treatments are carried out at first twice a day and usually, after a few days, once daily and then less frequently. In dealing with large wounds with sinuses the number of dressings is reduced to a minimum.

In general, when the treatment is successful it produces the same results as solutions of the calcium salt of the drug used locally. These are reduction in suppuration, increase of healthy granulation tissue and epithelium, decrease of pain in the lesion under treatment, and a rapid improvement in general well-being. Patients state that the filtrate stings to a moderate or, with a few batches, a severe degree when it is applied to a raw surface, but as a greater compensation it quickly reduces the tense throbbing pain and the burning sensation of the inflamed tissues from which many of them have suffered almost continuously for months or years. Experience has also confirmed that the drug is not a substitute for surgery but a very powerful ally to it, and in a complicated case repeated surgical measures may be needed to bring the benefits which they themselves are known to produce and to allow the penicillin the direct access to bacteria which it requires. In some cases of acute or chronic osteomyelitis, sequestrectomy may be needed after the filtrate has reduced the toxæmia and the inflammation of the soft tissues, but the benefit to the patient is still undoubted. Brief reports are given of all patients treated so far, with the exception of some very minor infections and some patients in whom treatment has been too recently begun for comment. The names of the surgeons who were in charge of the patients and who kindly supplied the notes are given in parentheses.

#### Case Histories

**Case 1.**—Male, 28 years. Chronic osteomyelitis of sacrum. Multiple sinuses. Injured in Germany, April, 1942. Admitted Feb. 22, 1944, with multiple intercommunicating sinuses. No

material change until instillation of penicillium filtrate started on March 13 and continued daily for 3 weeks and subsequently at shorter intervals. Marked improvement in general condition; diminution of discharge and of haemolytic streptococci. Hip mobility restored. Total penicillin, 1,500 units. (Mr. E. T. Bailey.)

**Case 2.**—Male, 25 years. Compound fracture of right femur and shell wound. Wounded Jan. 5, 1943. Admitted to Northern Hospital July 8, 1943. Plaster was applied in Tobruk four months previously. No material improvement after 3 months' sulphonamide treatment, blood transfusions, etc., until on Jan. 14, 1944, penicillium filtrate was instilled once daily for 8 days. Effect was progressive reduction in amount of discharge and of haemolytic streptococci, followed by gradual healing of 10-inch thigh wound and establishment of bony union. Total penicillin, 1,000 units. (Mr. E. T. Bailey.)

**Case 3.**—Male, 17 years. Staphylococcal osteomyelitis of tibia and abscess of thigh. Admitted June 30, 1943, for possible tuberculosis of right hip. Developed abscess of thigh Aug. 10 and acute osteomyelitis in upper tibial epiphysis six weeks later. Tibial cavity drained and daily instillation of penicillium filtrate begun Oct. 18, continued for one week, and repeated for another week a fortnight later. Progressive and rapid decrease of discharge and of *Staph. aureus* and haemolytic streptococcus; closure of cavity and restoration of normal x-ray appearance. Effect on abscess of thigh similarly treated: almost immediate response of previously intractable inflammation, with healing in four weeks. Total penicillin, 800 units. (Mr. E. T. Bailey.)

**Case 4.**—Through-and-through war wound above knee; recent sequestrectomy. 500 units instilled during week resulted in almost total healing in a month, comparing most favourably with cases without penicillin. (Mr. E. T. Bailey.)

**Case 5.**—Male, 8 years. Subacute osteomyelitis of tibia for 2 months. 300 units during 10 days caused rapid reduction of profuse pus and the granulation of 2 sinuses, with much improvement of general health. The penicillium filtrate treatment was started immediately after second operation. (Dr D. Kaye.)

**Case 6.**—Male, 21 years. Profuse suppuration for 3 weeks of finger with compound fracture of phalanx. 100 units during a week produced in that time a clean wound with healthy granulations. (Mr. R. A. V. Lewys-Lloyd.)

**Case 7.**—Male, elderly. Chronic osteomyelitis of tibia. Two sinuses were treated during 8 to 10 days with 140 units; one was practically healed and one quite healed and dry. In comparison, a third sinus was unchanged while treated with acriflavine in the same period; this sinus is now responding to penicillin. (Mr. R. A. V. Lewys-Lloyd.)

**Case 8.**—Female, 13 years. Sinus discharging for months following perinephritic abscess and nephrectomy. 500 units during 3 weeks caused cessation of discharge, much reduction in size of sinus, and general improvement in health. (Dr G. M. Palmer.)

**Case 9.**—Male, adult. Deep infected wound of palm 2½ in. by 1 in., of two months' duration; healing ceased. 30 units and mycelium during a week caused healthy granulation all over and rapid epithelization. (Mr. E. E. Bourke.)

**Case 10.**—Female, 46 years. Two syphilitic ulcers of leg, stationary for 5 years despite constant treatment. 300 units during a month greatly reduced swelling and pain of leg and reduced ulcers to less than half the area. Treatment is being continued. (Miss G. M. Sandes.)

**Case 11.**—Female, 45 years. X-ray burn and ulcer of big toe, lasting 6 years, with very slow improvement under treatment. Rapid improvement started by 2 weeks' treatment with calcium penicillin and continued to almost complete healing with 500 units of filtrate given during 5 weeks. (Miss G. M. Sandes.)

**Cases 12, 13, and 14.**—Three female children with gonococcal vulvovaginitis for 3½, 9, and 14 months, resistant to sulphadiazine (2) or sulphapyridine. 40 units each during 4 days resulted in cure, observed for four months. Filtrate retained in vagina by elevation of pelvis for half an hour after daily instillation. (Miss G. M. Sandes.)

**Case 15.**—Female, 32 years. Abscess in superficial tissues of abdominal wall associated with widespread surrounding erythema and rheumatic pains, lasting for 6 weeks after appendectomy. During 12 days 240 units produced cessation of suppuration and progressive healing of wound. (Miss G. M. Sandes.)

**Case 16.**—Female, adult. Operation wound for frontal sinusitis, indolent for two months, with inflammation of surrounding skin. 100 units followed by healthy granulation of wound and subsidence of skin infection. (Mr. Bedford Russell.)

\* Patients 1, 2, and 3 were demonstrated by Mr. Bailey and me at a meeting of the Clinical Section, R.S.M., on April 14, 1944.

**Case 17.**—Female, 38 years. Abscess and sinuses of abdominal wall for 12 months. 600 units during 7 weeks, with sulphapyridine powder during part of time, almost ended profuse suppuration, closed sinuses and gape of wound, and improved general condition. (Mr. I. Price.)

**Case 18.**—Female, adult. Large breast abscess with much swelling of surrounding breast; incised and one pint of pus removed. 200 units of penicillium filtrate instilled twice a day during five days reduced discharge to a little sero-pus and brought surrounding tissues to normal. (Dr. G. M. Palser.)

**Case 19.**—Female, 65 years. Cellulitis and suppuration in resutured abdominal operation wound. Local treatment by sulphacetamide (albucid) and by eusol produced very slow progress during two months; 150 units during 5 days ended suppuration, reduced sinuses and gape of wound, and produced healing edge all round. (Mr. W. T. Kenny.)

**Case 20.**—Female, 17 years. Two abscesses in right breast. The larger, after incision, treated with 300 units during 3 weeks, healed well in spite of a near-by pocket requiring another incision. This illustrated need for close contact of penicillin with the suppurating lesion, and the result was considered only moderately successful. (Dr. G. M. Palser.)

**Case 21.**—Male, adult. Osteomyelitis of tibia greatly improved in healthy granulation by 170 units; unopened abscess produced septicaemia, successfully treated by sulphathiazole. Rapid healing of sinuses and abscess then resumed. Septicaemia recurred. Systemic administration of penicillin needed. (Mr. E. T. Bailey.)

**Case 22.**—Female, 40 years. Acute breast abscess. After incision, 200 units in 9 days, followed by healing not more rapid than normal. (Dr. G. M. Palser.)

**Case 23.**—Female, 10 months. Subacute suppurative cellulitis of temporal region and brain abscess (probably due to *B. necrophorus*). Profuse suppuration in muscles of temporal and pterygoid regions subsided to oedema after 80 units during one week, but pus had rapidly decreased previously without penicillin. Necrosis of mastoid cells found at operation, and child died same day. At necropsy a well-encapsulated abscess in temporal lobe of brain without apparent connexion with surface; no suppuration in tissues outside skull. Effect of filtrate doubtful. (Mr. McCrea.)

**Case 24.**—Male, elderly. Chronic osteomyelitis and sinus of thigh. Very little improvement with 280 units of filtrate in a week followed by 250 units of calcium salt, although *Staph. aureus* isolated was quite sensitive to penicillin. (Mr. E. T. Bailey.)

### Comment

It is considered that in the first 19 of these patients the filtrate has been successful, sometimes to a quite unexpected degree; in the other 5 success was partial, doubtful, or absent. It is claimed, however, that this series shows that the effects expected of penicillin can be obtained by the unconcentrated filtrate when it can be applied locally to tissues infected with bacteria sensitive to it.

Since the filtrate can be readily produced and assayed in a bacteriological laboratory which has a well-trained staff, it can be used for local application to acute and chronic abscesses, sinuses, and ulcers as a substitute for the partially purified substance until the latter is available. Since the filtrate retains its potency at 4° C. for at least a week, it is possible to provide a steady supply by the production of one or two batches weekly.

A specimen was dried in several portions on April 25, 1944, in Major J. E. McCartney's laboratory by Mr. A. G. Rayner by the method which he recently described (A. G. Rayner, 1943), and when the dried substance is dissolved in sterile water some portions have retained full potency for 8 days, but others are found to have lost it entirely immediately after drying. This irregularity is being investigated.

It has been found in this series, as it has been by other observers, that, in the course of treatment of external lesions by penicillin, *B. pyocyaneus* becomes prominent and may hinder healing after the penicillin-sensitive bacteria have been reduced or banished. I have confirmed, by sensitivity tests similar to those used for assay of penicillin, that *B. pyocyaneus* (4 strains) is quite sensitive to saturated solutions (4%) of boric acid; and Dr. G. M. Palser has found in three patients that the boric acid solution reduced the suppuration due to *B. pyocyaneus* and permitted continuation of healing, although the organism recurred when boric acid was stopped before healing was complete. This seems worth further trial.

### Summary

Crude penicillium filtrate containing 4 to 10 units of penicillin per c.cm. may be used successfully for treating many acute and chronic inflammations by local application, in place of the partially purified calcium salt of penicillin: the filtrate can be dependably produced and assayed in a bacteriological laboratory in useful quantities.

I wish to express thanks to the surgeons for their co-operation, to Drs. A. Martin and C. H. Carrington and others of Imperial Chemical (Pharmaceuticals) Ltd., for imparting much of their experience; to Dr. J. H. Waelsch and Mr. E. Martin for helpful suggestions; and especially to Mr. R. M. Sandercott for his enthusiasm in developing and carrying out the technical work.

## AUTOLYSED YEAST IN THE TREATMENT OF NUTRITIONAL MACROCYTIC ANAEMIA

BY

G. R. SIPPE, M.B., B.S.

(From the Bacteriological Laboratory, Reduit, Mauritius)

Nutritional macrocytic anaemia has been reported from India, China, Africa, and Macedonia, and there is strong evidence that it is a deficiency disease due to the absence of one or more essential vitamin-like factors in the diet. It will therefore tend to occur in communities where, for economic or other reasons, foodstuffs containing adequate supplies of these factors do not normally form part of the diet. Thus in the poverty-stricken areas of Macedonia, Fairley *et al.* (1938) found the condition to be common among refugee peasants, and Wills (1934) stated that it was especially rife in Southern India, where rice is the staple food. In Mauritius it is particularly common among those members of the community who, for religious reasons, do not include beef flesh in their diet. The condition is found in both sexes, and is most prevalent during the second and third decades. It is especially apt to appear during the latter half of pregnancy, and it is probable that in cases of malarial splenomegaly the disease is aggravated by excessive destruction of normal and abnormal erythrocytes by the hypertrophied reticulo-endothelial system (Fairley *et al.*, 1938; Hughes and Shrivastava, 1931).

Although it is agreed that nutritional macrocytic anaemia is a deficiency disease, the part played by the factor or factors whose absence is responsible for the condition is obscure. Autolysed yeast (marmite) (Wills, 1934) and crude liver extracts both produce a maximal reticulocyte response, and Wills found that the factor or factors were water-soluble, heat-stable in an acid medium, and partially resistant to autoclaving in an alkaline medium; and Formijne (1940) has shown that potent substances can be obtained by extraction of beef flesh with 70 to 80% alcohol, but that the potency is lost in concentrations of 90% alcohol.

Wills *et al.* (1937), in the course of experiments on rhesus monkeys suffering from an artificially induced anaemia which was considered to be the counterpart of nutritional macrocytic anaemia in man, found anahaemin to be ineffective. This was surprising in view of its efficacy in cases of Addison's pernicious anaemia. Trials with anahaemin in nutritional macrocytic anaemia in man have given variable results. Wills and Evans (1938) considered it to be ineffective, and Napier *et al.* (1938) stated that some cases responded well while others failed to show any response. Fairley (1940) found very large doses to be effective in an Indian suffering from the condition.

Wills *et al.* (1937), in further experiments with campolon, which was fractionated into soluble and insoluble portions by saturation with ammonium sulphate, found that the insoluble

portion (containing the major part of the anahaemin) was very potent in cases of pernicious anaemia and inactive in monkey anaemia, and that the soluble portion was active in both conditions. It is suggested that the potency of the soluble fraction may be due to some of the anahaemin in the crude extract not being precipitated, or to a new substance not precipitated by the ammonium sulphate.

It is possible that there are two essential factors in the diet (Wills *et al.*, 1937): one which reacts with the intrinsic factor to form the liver principle, and the other—also found in the crude liver extract and not precipitated by saturation with ammonium sulphate—which is necessary for the activity of the pure liver extracts. Probably the commonest source of these factors in the average diet is beef flesh, and it has been shown that autolysed yeast (marmite) is extremely potent in the condition under discussion. Watery yeast extract and dried yeast powder (Wills, 1934) are inactive.

In treating nutritional macrocytic anaemia, the reasons for the non-consumption of foodstuffs containing adequate quantities of the necessary factors—namely, economic hardship and racial and religious prejudice—must be closely borne in mind, and it must be remembered that the condition will relapse unless means are adopted for the continuous supply of the essential foodstuffs. Autolysed yeast would appear to be the ideal substance, as not only is it rich in the necessary factors and acceptable to all communities, but, on account of its cheapness, can readily be made available to all sections of the public. Autolysed yeast is also rich in certain members of the vitamin B complex, and in Mauritius has proved valuable in the treatment of pellagrous dermatitis and angular stomatitis and glossitis (Dr. André), two conditions which by virtue of the poor diet tend to occur in regions where nutritional macrocytic anaemia is found.

A number of cases of nutritional macrocytic anaemia have been treated with yeast obtained locally as a waste product in the manufacture of alcohol by fermentation of molasses. The yeast mixture is obtained from the bottom of the vat after fermentation has ceased and the top fluid has been run off. Normally this sediment is discharged on to the fields, where on account of its nitrogen content it has some value as a fertilizer. The sediment (yeast mixture) has the consistency of thin gruel and is brownish in colour. The taste is not pleasant, but when given with water and a little sugar the mixture is more palatable.

At present work is proceeding in an attempt to render the mixture more agreeable to the taste and to obtain it in a more concentrated form, since patients very occasionally are unable to take it on account of the vomiting and diarrhoea it may produce. This intestinal upset is probably due to the taste and acidity of the mixture, which has to be taken in comparatively large amounts, and to the insoluble material present in the residue. It is hoped that preliminary washing associated with some form of evaporation in pans, similar to that employed in the preparation of salt, may prove satisfactory.

Before use it is advisable to pass the mixture through a coarse filter, such as cheese-cloth or a fine screen. Afterwards it is sterilized at 70° C. for one hour, which not only kills any pathogenic organisms that may be present but also the yeast cells themselves, and autolysis is thus hastened. It is probable that liberation of the potent factor or factors occurs only after autolysis has taken place. In these experiments amounts of yeast sufficient for two to three weeks' treatment were prepared at one time and administration was started immediately after sterilization. No work has yet been done to ascertain whether prolonged keeping will increase the potency of the preparation. The quantity of the mixture necessary to produce a satisfactory blood response has been found to be from 3 to 6 oz. a day. In pregnancy, especially during the latter half, the bone marrow may fail to react even with very large doses, and this unsatisfactory feature has been noted by Davidson *et al.* (1942). It may be due partly to increased demands by the foetus for the liver principle and a temporary inhibition of the bone marrow during pregnancy, and partly to the absence of some essential factor in the diet.

Samples of yeast mixture from two separate distilleries (Nos. 1 and 2) were analysed, with the following results:

TABLE I.—Average Composition of Yeast Liquor

Liquor No.	Solids	Protein	Yeast (approx.)	Calcium	Phosphorus Pentoxide	Iron	Calcium Sulphate	Ash	Density
1	26.6	2.0	4.0	4.5	0.16	0.024	9.2	16.5	1150
2	15.6	4.0	8.0	0.6	0.23	0.040	—	3.0	1060

TABLE II.—Average Composition of Solids from Yeast Mixture

Liquor No. (% Solids)	Protein	Yeast (approx.)	Calcium	Phosphorus Pentoxide	Iron	Calcium Sulphate	Ash
1 (26.6)	6.74	13	18.4	0.85	0.09	32.0	57.20
2 (15.6)	27.38	54	3.9	1.50	0.27	—	19.25

In distillery No. 1 the molasses used for fermentation were obtained from a sugar factory producing white (bleached) sugar, and in No. 2 the molasses were from a factory producing raw (unbleached) sugar. The large amounts of inert calcium sulphate present in the sample from distillery No. 1 result from the bleaching process, and therefore are not found in the sample from the second distillery. In the experiments to date the yeast has been obtained solely from distillery No. 1, but it is proposed in future to use the mixture from distilleries of the second type in view of the much larger quantities of yeast present in the sediment.

The following are details of cases treated with this yeast sediment. Owing to the isolation of the laboratory from the hospitals, a full blood examination was not always possible, nor was a daily reticulocyte count practicable. All cases showed definite hyperchromia and marked macrocytosis and anisocytosis. In Cases 1, 3, 5, and 6 gastric analysis was carried out after the yeast treatment; in Case 4 it was done before treatment. Free acid was found in all. Patient No. 2 was unable to swallow the tube even after treatment had finished.

Case 1.—A male Moslem aged 43 had been for four months complaining of weakness, dyspnoea, and palpitations. When seen he was weak, and pallor of the tongue and conjunctiva was extreme. The spleen was not palpable. The blood findings were: R.B.C., 760,000 per c.mm.; Hb, 2.94 g. (Sahli); W.B.C., 4,500 per c.mm.; mean corpuscular haemoglobin, 38.7  $\gamma$ . A few trichuris eggs only were found in the stools, and the urine was normal. Yeast, 6 oz. a day, was ordered, but by mistake the patient actually took 8 oz. a day. After two weeks he began to improve rapidly, and eight weeks after starting treatment the blood findings were: R.B.C., 4,050,000 per c.mm.; Hb, 11.9 g. (Sahli); W.B.C., 7,200 per c.mm.; M.C.H. 29.7  $\gamma$ .

Case 2.—A male Hindoo aged 21 had complained of weakness, palpitations, and dyspnoea on exertion for the last three years. He was pale and weak when seen. The blood findings were: R.B.C., 720,000 per c.mm.; Hb, 4.34 g. (Sahli); W.B.C., 6,150 per c.mm.; M.C.H., 60.0  $\gamma$ ; packed cells, 12.95%; mean corpuscular volume, 179.8 c. $\mu$ . No malaria parasites were found. The stool examination showed no ova or protozoa; the Kahn reaction was positive (+); van den Bergh, 1.75 mg. bilirubin per 100 c.cm. Yeast mixture, 3 oz. a day, was ordered. Six weeks after starting treatment 20 gr. of totaquina was given daily for four days. Two weeks later he complained of burning of the mouth, and some glossitis and angular stomatitis occurred. This disappeared in about 16 days without local treatment. Two weeks before treatment ceased the dose of yeast was increased to 6 oz. a day, and the blood findings after 16 weeks' treatment were: R.B.C., 4,860,000 per c.mm.; Hb, 15.4 g. (Sahli); W.B.C., 7,700 per c.mm.; M.C.H., 31.4  $\gamma$ . The patient is now back at work and in excellent health.

Case 3.—A female Hindoo aged 24 had been sick for three months with vomiting, palpitations, and weakness. When seen, pallor was extreme and the blood findings were: R.B.C., 640,000 per c.mm.; Hb, 2.66 g. (Sahli); W.B.C., 7,500 per c.mm.; packed cells, 8.9%; M.C.H., 41.5  $\gamma$ ; M.C.V., 139.0 c. $\mu$ ; van den Bergh, 1.5 mg. bilirubin per 100 c.cm. No malaria parasites were found. The stools showed no ova or protozoa. The Kahn reaction was negative. The patient was four months pregnant, and the spleen was not palpable. Treatment with yeast, 6 oz. a day, was begun, and was supplemented ten weeks later with ferri et ammon. cit. gr. 90 daily as there was a lag in the haemoglobin percentage. Four weeks later the yeast was increased to 9 oz. daily, and the following week a stillborn infant was delivered. Improvement was rapid for the first eight weeks, after which the stress of the six-months pregnancy was

manifest, and the count remained more or less constant at this level until after confinement. When she was last seen her condition was excellent. The blood findings were: R.B.C., 3,990,000 per c.mm.; Hb, 12.04 g.% (Sahli); W.B.C., 8,650 per c.mm.; M.C.H., 30.2  $\gamma\gamma$ .

**Case 4.**—A male creole aged 22 had been sick for nine months with weakness, dyspnoea on exertion, and bleeding from the gums. When seen, pallor was marked, and there was some periodontal ulceration and sponginess of the gums, with secondary infection of the left wisdom tooth and oedema of the left cheek. The blood findings were: R.B.C., 1,890,000 per c.mm.; Hb, 8.26 g.% (Sahli); W.B.C., 5,600 per c.mm.; packed cells 27.4%; M.C.H., 43.7  $\gamma\gamma$ ; M.C.V., 144.9  $\mu$ ; bleeding time, 4 min.; coagulation time, 6 min. Subtertian and benign tertian malaria parasites were found. Van den Bergh: 0.6 mg. bilirubin per 100 c.cm. Stools: ankylostome ova +; urine: pus cells +. Spleen just palpable. Treatment with yeast 3 oz. daily was begun, with quinine gr. 15 intramuscularly for four days. No treatment for hookworm was given. The patient was unusually co-operative, and in eight weeks was back at work, the R.B.C. count being 4,350,000 per c.mm., the Hb 13.44 g.% (Sahli), and the M.C.H. 30.9  $\gamma\gamma$ .

**Case 5.**—A female Hindoo aged 38, 7-para, had complained of extreme weakness and troublesome diarrhoea since her confinement five weeks previously. Pallor and weakness were marked, and the blood findings were: R.B.C., 620,000 per c.mm.; Hb, 3.22 g.% (Sahli); M.C.H., 51.9  $\gamma\gamma$ . No malaria parasites were found. Stool examination showed neutral fat and fatty acids ++; no ova or protozoa were present. The spleen was palpable on inspiration. Clinically the case did not resemble sprue, and a diagnosis of nutritional macrocytic anaemia was made. Yeast, 6 oz. a day, was given. Mist. bismuth. sed. 1/2 oz. four-hourly was prescribed for the diarrhoea, which cleared up within 48 hours and did not trouble the patient again except during several nights one week later. This again responded to the bismuth mixture. Two weeks after starting treatment mild glossitis and angular stomatitis similar to Case 2 were noted. This disappeared as the clinical condition improved. The patient was not seen again until approximately five months later, during which time the yeast had been taken irregularly. She was, however, very well. The R.B.C. count was 3,620,000 per c.mm.; the Hb 12.3 g.% (Sahli), and the M.C.H. 34.2  $\gamma\gamma$ .

**Case 6.**—A male Hindoo aged 26 had been ill for five months with weakness, palpitations, and dyspnoea. Pallor of the mucous membranes was marked, and the blood findings were: R.B.C., 1,320,000 per c.mm.; Hb, 6.30 g.% (Sahli); M.C.H., 47.7  $\gamma\gamma$ . No malaria parasites were found. He was given yeast, 2 oz. four times a day, and improvement was rapid and continuous. In seven weeks the R.B.C. count was 4,100,000 per c.mm., the Hb 13.8 g.% (Sahli), and the M.C.H. 33.8  $\gamma\gamma$ . He is now well and has resumed work.

### Conclusions

Sediment obtained from distilling-vats after fermentation has ceased is potent in the treatment of tropical macrocytic anaemia. This potency is due to the presence of autolysed yeast, which has been shown to contain the factor or factors necessary for the normal maturation of red cells and in whose absence an anaemia of the macrocytic type develops. Certain members of the vitamin B complex are also present in the yeast sediment, which has been used successfully to treat angular stomatitis and glossitis and pellagrous dermatitis.

It is preferable to obtain yeast sediment from factories producing unbleached sugar, as the yeast content is higher and calcium sulphate is absent. The latter may produce diarrhoea, possibly on account of its bulk. The yeast sediment used is obtained as a waste product and hence it is cheap. It is also acceptable to religious sects that will not eat beef flesh.

Concentration of the yeast extract and distribution from hospitals, estates, child welfare centres, and schools might be undertaken with valuable results in a country where tropical macrocytic anaemia is common, such as it is in Mauritius.

I am indebted to Mrs. D. Collins, M.Sc., for the analysis of yeast samples; to superintendents of the various district hospitals for permission to treat cases; and to the manager of Medine estate for supplies of yeast. I should like also to thank Dr. d'Arifat, Ag. Director, M. and H. Dept., for permission to publish this paper.

## FAMINE OEDEMA IN PRISONERS OF WAR

BY

DOUGLAS S. STEVENSON, M.B.E., F.R.F.P.S.

Brigadier, A.M.S.

Oedema or dropsy occurring under conditions of starvation or of semi-starvation has been recognized since the earliest days, in particular being associated with war, and records of it occur in literature of the ancient world. In more modern times Napoleon's army is stated to have suffered in this way in its retreat from Moscow in 1812, and there have been such records from time to time under famine conditions in Ireland, India, China, the Siege of Paris, and Central Europe from 1914 onwards during the 1914-18 war; and in these histories the clinical picture has been fully described and many theories of causation advanced (*Official History of the War*, 1914-18). These theories are all, of course, from the days when accurate biochemistry was unknown and the vitamins equally so, although it was appreciated that the empiric use of certain foods—e.g., citrus juice—did help to cure conditions such as scurvy. A frequent comment in some records is that no evidence of scurvy appeared and that people died of dropsy alone—a clinical finding worth remembering, as scurvy was greatly feared in times of want. Another observation is that in the civil population dropsy affected the adult males rather than the women and children, and it is generally agreed that when famine conditions were ameliorated most of the surviving sufferers were restored to normal health. The mortality figures vary greatly, in some cases being 50%; but seldom is there any clear reasoning as to the cause of the dropsy—simply that it was due to insufficient food.

### Aetiological Factors

What are the possible and what the probable causes of such oedema or dropsy? First, avitaminosis beriberi—the wet type of beriberi with its leg weakness, unsteadiness of gait, dyspepsia, anaesthesiae, and paresthesiae—must be considered. Secondly, nephritis. Richard Bright's (Boyd, 1938) description in 1827 of oedema and albuminuria as the main clinical features and the naked-eye observations of the diseased kidneys is historic. The war nephritis described in detail in the *Official History of the War* (1914-18), and considered to be no different from the acute nephritis of civil life has also to be borne in mind, noting that dyspnoea was often the presenting symptom, oedema was of short duration, and acute uraemia was frequent. Thirdly, we have food deficiency: famine oedema, the German *Oedemkrankheit* or *Kriegsödeme*, the French *Oedème de la famine ou de la guerre*—oedema associated with famine and commonly with war, so frequently partners. These are the most likely causes of oedema occurring in comparatively large numbers of persons and under the circumstances to be stated.

### Cases from German Prison Camps

Recent examination of some repatriated prisoners of war captured in May-June, 1940, in France, reveals that these men developed, in one case at four months, in an average at eleven months, and in one case at as long as fifteen months after capture—i.e., in 1941, and while in Germany—oedema of legs, face, and genitals, preceded by malaise, dyspnoea, and severe headache. Their condition otherwise at that time is not known to us, nor have we any record of the results of the examination of their urine. They were stated to be suffering from nephritis. After capture in 1940 the men were marched considerable distances on an extremely poor diet and in battle dress, some without overcoats, eventually reaching prison camps in different parts of Germany, where they were put to work, still on a diet very low in quality and quantity. This diet is described by each of them separately as consisting daily of one-fifth of a loaf of black bread, a pint of thin soup with some cabbage in it, and a few half-rotten potatoes. On occasion a portion

of swede turnip was given in place of potatoes. This diet does not work out at the claimed German ration containing 55 g. of protein a day and amounting in energy value, from this and other ingredients, in all to about 1,800 calories, but was in fact gravely lacking in protein, especially good-quality animal protein, and was far from sufficient for men who were put to work. In addition the winter of 1940-1 was severe and their clothing inadequate. At about this time—spring, 1941—it was reported by delegates of the Protecting Power and the International Red Cross Committee that there was an outbreak of nephritis among the prisoners of war. The chief symptom was said to be oedema, but hypertension, haematuria, and albuminuria were also reported to be present. These men, diagnosed as cases of "nephritis," are presumably those who have now been repatriated.

Their own description is that their morbid condition began in every case with what they describe as "asthma" or as such shortness of breath that they required to attain a position of rest in the sitting posture. Some stated that they had much diarrhoea; two said that they were constipated; none of them was clear about any great alteration in their output of urine, but some had to rise for this purpose from time to time through the night. Oedema now appeared in their ankles and faces, often becoming extreme and involving also the genitals, the abdomen, and even the hands. Headache became very distressing, and they felt confused in their minds and unable to concentrate on things like simple games and books. None of them described any defect of vision or any superficial ocular discomfort, but their eyes ached with their headaches. When asked whether they noticed any diminution of visual acuity in the dark they were clearly at a loss, and it may be presumed that night-blindness was not present (Weekers, 1943). They were admitted to the local prison camp hospitals, where most remained for upwards of three months and some for as long as a year, although in the majority the oedema cleared up after some 6 to 8 weeks, sometimes relapsing when they got up. While in hospital they were given a rather more generous diet, salt-free, and some had injections, which are presumed to have been diuretics, while others had blood-letting performed. They all knew of other cases in their camps and hospitals, but these others are not with them now.

Red Cross parcels began to arrive about the spring of 1941, and the men were able to get protein food in greater quantity, with this the oedema and all other symptoms cleared up fairly rapidly, but after a period of failure of parcels to arrive or after return to work the oedema was apt to reappear. On disappearance of the oedema their limbs were lamentably wasted.

These men, now in this country and on an adequate diet, have no oedema, no headache, and no symptoms or signs to suggest a fairly recent nephritis, and their general nutrition is reasonably good. Their urine is quite normal, chemically and microscopically; blood pressure, ophthalmological examination, blood urea, and renal function tests are also normal. The men do have symptoms, such as pain in the back, aches generally, depression, and post-prisoner-of-war mentality, and they fear that their kidney lesion will recur. Many of them believe that they are no longer virile, or that, if virile, they are sterile, and reassurance as to this has helped them considerably.

Reviewing their state in 1941 and their present condition, and thinking of the causes of such oedema previously noted, it is thought more than probable that they come under the third category—food-deficiency oedema. Had they been true nephritics it is unlikely that they would have recovered so completely and been without signs or symptoms of nephritis to-day. They did not show the ataxia, leg weakness, dyspepsia, and sensory symptoms of beriberi, nor did they reveal the oral signs that are so often associated with a vitamin B deficiency.

This condition of famine oedema is essentially a hypoproteinaemia (McLean, 1922; Youmans, 1941) and is not a vitamin deficiency (Aykroyd, 1930), although some degree of this may also occur; in suggested proof of this the answers to a number of questions—avoiding leading questions so far as was possible

—revealed that, as already stated, no eye abnormalities occurred; none of them had any signs or symptoms referable to the mouth, such as painful tongue, angular stomatitis (Clarke and Prescott, 1943), bleeding or painful gums; none had pains in the legs or arms; and none had at any time haemorrhages or skin lesions, thus suggesting strongly that even the prison diet contained sufficient to eke out the men's own stores of vitamins A, B, pellagra-preventive factor, C, and K. Admittedly they had headache intense enough to disturb their powers of concentration, and depression, which under the circumstances was not unexpected; but these can be explained without postulating gross vitamin B deficiency.

### Commentary

The condition described is one of much interest and importance to-day in view of its probable widespread distribution. It has been recognized before, and its aetiological factors have been worked out with observations on the biochemistry and on the question of vitamin or endocrine disturbances. Starling (1896a, 1896b) long ago showed the existence of an equilibrium between capillary blood pressure and colloid osmotic pressure, and that disturbance of this in the way of lowered protein in the blood would, in the presence of sufficient sodium chloride, the chief solute of oedema fluid, permit the diffusion of fluid from the blood into the tissues. McLean (1922) pointed out the importance of posture and of gravity in the production of oedema when blood protein was lowered, and showed that complete rest in the prone position would bring about a reduction of such oedema (Weech, 1936), also noting the alteration in the blood of the albumin-globulin ratio, the lowering of the former—often by a half, producing a ratio of 2.2 instead of the normal 4.2—being responsible for oedema, the globulin rarely going below normal. Aykroyd (1922) and Weech (1936) discuss treatment in some detail, mentioning animal experiments, and stress the importance of relying on a good mixed diet with sufficient but not excess protein, this tending to produce gastro-intestinal disturbances such as diarrhoea. In this respect they consider that it is not reasonable to try to give protein intravenously—e.g., in the form of plasma or stored blood transfusion—because the amount transfused cannot contain more than a limited quantity of protein. The total of fluid and the effect of such a procedure is only likely to cause greater oedema, pulmonary and otherwise, with possibly fatal results. This should be borne in mind when starved populations are being relieved. Relief should be by good mixed diet alone—not too high in protein, and containing, so far as possible, all the accessory food factors (*Bulletin of War Medicine*, 1944). Such a diet can be worked out comparatively simply without including a great many complex substances. McCarrison (1920) gives an excellent survey of the endocrine disturbances brought about in such conditions of semi-starvation, and these might be studied with advantage by persons organizing relief.

The importance of these observations in regard to our own returned prisoners would appear to be that the men think that they have had a serious kidney disease, that it will probably recur, and that their virility has been sapped. They therefore need careful reassurance as to the true facts—namely, that they have not been suffering from a pathological condition which has done them any permanent harm. It is important that hospitals generally should be advised of the existence of this state of matters, because in a number of cases these men have been instructed to take great care to avoid getting wet feet, or cold, and warned to wear woollens next their skin and generally against hard work. Their cases have mostly been labelled "nephritis, recovered from," and a guarded prognosis has been given in the form of a recommendation that they could be employed in Category C. In view of the anxiety state which has been produced in most of them (Newman, 1944) it would perhaps be wiser that some should be discharged from the Services with the reassurance that before long they will find themselves fit normal men, able again to take their places in the general labour market, and that such of them as wish to remain in the Services should be kept temporarily in a lower category and rehabilitated gradually at a convalescent depot.

I wish to thank Lieut.-Gen. Sir A. Hood, Director-General, Army Medical Services, and Major-Gen. J. A. Manifold for permission to publish; and the Royal College of Physicians, Edinburgh, for use of their library.

## Medical Memoranda

### Prevention of Industrial Dermatitis

The admittedly high incidence of industrial dermatoses in many of our war factories is a serious matter, and doubtless the present increase is attributable to several factors, among which the difficulty of selecting personnel for hazardous jobs, the introduction of new hazards and inexperienced workers, and inadequate facilities for proper cleansing of the skin all play a part. To these must be added the difficulty in getting certain types of work-people to use thoroughly such preventive measures as are provided against well-known skin hazards. Constant supervision by the foremen and charge-hands is essential to deal with this, and, in addition, the works doctor, by paying frequent visits to each department, must see that such supervision is exercised. Barrier creams, for which so much is often claimed, have their uses, but in my experience they are disappointing, and necessarily depend too much on the intelligent co-operation of the workman.

Two of the most common and most troublesome varieties of industrial dermatitis met with in aircraft and other machine factories are undoubtedly oil acne from close and long contact with brown machine-cutting oils, and paraffin dermatitis due to degreasing and cleaning engine parts in paraffin baths and bench troughs. These two hazards may give rise to a high incidence of skin trouble and to a very large amount of compensatable absence from work, and, of course, interruption of production and constant replacement of skilled personnel, who dislike the jobs. Faced with this problem in several of the factories in my medical charge, I sought in vain for some new, easily applied, and efficient means of meeting it, until my attention was arrested by a leading article on skin hazards in aeroplane manufacture (*B.M.J.*, 1942, 1, 188), reviewing a report by L. Schwartz and J. P. Russell (*Publ. Hlth. Rep.*, Wash., 1941, 56, 1581) on the subject, in which reference was made to the use of neutral sulphated castor oil in 2% wetting agent as a substitute for soap after work. This suggested to me the possible value of such an emulsion as a skin cleanser after hazardous work instead of using, before work, barrier creams or lanolin mixtures, which invariably were dissolved off by the oil or paraffin.

With the assistance of my pharmaceutical suppliers various experiments were made and several mixtures were tried, including three of a different nature kindly sent me for trial by Dr. M. W. Goldblatt, of Imperial Chemical Industries. Ultimately a comparatively cheap source of supply of the neutral sulphated castor oil was found; this was obtained in bulk and the wetting agent was added. It is distributed, where indicated throughout our factories, in gallon tins or bottles to the departments concerned, which dispense it to each wash-place in a round "elastoplast" tin, the lid of which is pierced with two opposing 1/4-in. holes. Directions for use are put over the wash-place, and consist of the simple instruction to wash the hands in water (hot or cold), then, while still wet, to pour a tablespoonful of the "hand cleanser" into one palm and rub well into both hands and forearms. It is then rinsed off in cold water. This procedure has proved an immediate and popular success, the skin being left clean, supple, and quite comfortable, both after long soiling with machine-oil or engine-grease, and after immersion in paraffin.

The use of this cleanser has since been extended with equally good results to various other jobs the chemical agents of which remove the normal sebaceous matter of the skin and cause a dry fissured dermatitis so prone to secondary infection; and to the stores, where the handling and cleaning of rust-proofed

and greased bar and sheet metal is a frequent cause of skin eruptions. The rubbing down of plaster castings, causing traumatic dermatitis, had also given trouble, and this, too, is obviated by the use of the "hand cleanser." The method was first put into use in our main factory in Nov., 1942, and the following table shows the marked reduction already achieved both in the incidence of all forms of dermatitis in the factory and in the incidence of oil acne and paraffin dermatitis in the machine shops alone:

	Dermatitis Incidence			
	Factory		Machine Shops Only	
	1942	1943	1942	1943
Average operative personnel ..	3,300	3,350	500	505
Cases not losing working time	375	162	67	17
Cases losing time beyond shift	39	23	5	1
Total Cases .. ..	414	185	72	18
Percentage .. ..	12.5%	5.7%	14.2%	3.5%

Oil acne affecting the front of the thighs due to oil-saturated aprons has been prevented by waist-high metal guards on the automatic cutting machines.

I have to thank the Senior Medical Inspector of Factories for his interest in and sympathetic attitude towards this experiment and its results, and it is with his approval that this preliminary report is published. His department of the Ministry of Labour has sent a member of its Dermatological Advisory Panel to investigate my method and dermatitis statistics, and doubtless will consider the question of its general adoption. This, however, must depend upon the Ministry of Food's making a higher allocation of the oil to supplement the present very limited supply of the raw material.

N. HOWARD MUMMERY, M.R.C.S., L.R.C.P.

Aircraft Factory Medical Officer; Ex-Chairman  
Association of Industrial Medical Officers.

### Skin Eruption due to Luminal

In the course of psychiatric practice one occasionally meets with instances of the intentional swallowing of a large quantity of luminal (gr. 50 to 100), but recovery usually ensues with energetic treatment. On the other hand, from time to time instances of cutaneous eruptions after the ordinary use of luminal have been recorded, though these cases must be very rare. The following recent case gave rise to much interest.

#### REPORT OF CASE

The patient, an unmarried woman aged 55, has been resident in this mental hospital since Oct., 1932, when her case was diagnosed as acute mania. She has been mentally deranged for 23 years, but showed no evidence of organic disorder until Dec., 1942, when she had two spontaneous epileptic convulsions. The Kahn test was negative, but the pupils were unequal and cerebral arteriosclerosis was suggested. In July, 1943, she again had epileptic fits, and was given luminal (phenobarbitone) 2 gr. twice daily, starting on July 19.

On Aug. 8 a morbilliform rash was noticed on various parts of the face, trunk, and limbs. It extended rapidly, and became especially thick and confluent on the back and on the extensor surfaces of the arms and legs, leaving the flexures comparatively free. The temperature on the first day was 103.2°, and a mild pyrexia persisted for two weeks, varying from 99 to 101°. On the seventh day of the rash the cervical glands were enlarged, but there was no abnormality of the mouth or pharynx. At the end of two weeks the rash began to fade. On the tenth day of the rash a blood count showed a slight leucocytosis: red cells, 4,530,000 per c.mm.; Hb, 90%; C.I., 1; white cells, 10,500 per c.mm.—polymorphs 78%, eosinophils 1%, basophils nil, lymphocytes 17%, monocytes 4%. The luminal was discontinued on Aug. 8. There was considerable desquamation when the rash had faded, and it was not until about five weeks after the drug had been stopped that the skin recovered its normal appearance.

On Dec. 14 the patient was again put on luminal. This time 3 gr. was given twice daily. After a week an eruption appeared on the limbs; but it was much less intense, and disappeared in two or three days in spite of continuing with the drug. There was no pyrexia. The blood calcium on Dec. 22 was within normal limits. She is still taking the drug daily without any further skin trouble.

#### COMMENT

Diagnosis was at first in some doubt, but the possibility of specific fever was excluded and a drug eruption suspected. This was confirmed by reference to the literature. Menninger (*J. Amer. med. Ass.*, 1928, 91, 14) recorded 3 cases of his own and collected records of 41 others. He found that a luminal eruption may arise in one of two forms—either an early one with urticarial wheals occurring soon after administration of the drug, or a later maculo-papular eruption sometimes like scarlet fever and at other times like measles. The latter type of rash is accompanied by pyrexia in more than 50% of cases, the eruption

tion usually not appearing until some days after the drug is first administered, and it may recur when the drug is renewed. There is no constancy in the dose giving rise to the eruption, which usually lasts a few days after the drug is stopped or may take some weeks to disappear, when there may be heavy scaling or peeling. The cervical glands are sometimes enlarged and occasionally there is a leucocytosis with an increase in eosinophils. Gastro-intestinal symptoms, headaches, dizziness, stomatitis, pharyngitis, and conjunctivitis have also occurred.

The immediate withdrawal of the drug is the only effective way to give relief. Apart from that, only simple local applications to relieve discomfort are necessary. Intravenous injection of 5 c.cm. of a 10% solution of sodium thiosulphate daily for 5 or 6 days has been recommended for obstinate and severe rashes.

The rarity of luminal rashes suggests that there is some personal idiosyncrasy to the drug. It has also been suggested that it is due to calcium or alkali deficiency. Menninger states that all we can say about it is that it is probably a selective tissue reaction to the drug dependent upon constitutional factors about which we are still ignorant.

F. T. THORPE, L.R.C.P., D.P.M.,  
Wadley Mental Hospital, Sheffield.

### Neorsphenamine and Infective Hepatitis

In an article published in the *Journal* for Aug. 28, 1943 (p. 261), Dr. D. R. Macdonald refers to the view that jaundice occurring during the treatment of syphilis with neorsphenamine may be due to the synergic action of neorsphenamine with the causal agent of infective hepatitis, probably a virus. Cases of jaundice that have recently been occurring in the unit to which I am the regimental medical officer seem to illustrate this view.

I have been with the unit for two and a half years, during which time we have been stationed in Northern Ireland, England, Gibraltar, and, now from March, 1943, in a "Plains" station in India. Two sporadic cases of infective hepatitis occurred in the unit in Aug., 1941, and March, 1943, and one case of transient jaundice in a man receiving neorsphenamine appeared in November, 1942. During this time there were always some men in the unit receiving weekly injections of neorsphenamine, the numbers varying, and averaging from four to five under treatment at any one time.

#### A RECENT SERIES OF CASES

During the five months from Aug. 1 to Dec. 31, 1943, a series of cases of jaundice appeared. Excluding cases in patients receiving neorsphenamine, 12 cases occurred and were admitted to hospital. The onset of jaundice was preceded by about four or five days by symptoms of nausea and epigastric discomfort and sometimes vomiting. The cases occurred singly, and were evenly spread over the period. At this time seven men of the unit were receiving regular injections of neorsphenamine, and out of these six developed jaundice and showed symptoms similar to the cases of infective hepatitis. Again the cases occurred singly and were spread evenly over the four months. The strength of the unit during the period was about 900. The men were receiving courses of neorsphenamine identical to that given to other cases during the long period when jaundice was not seen. Each had finished one course of ten weekly injections: in one case jaundice developed at the end of a rest period of four weeks, and in another after the first injection of a second course at the end of four weeks' rest. These facts seem to indicate that the jaundice was not a simple intolerance to arsenic.

#### DISCUSSION

Though the series of cases is a small one there does seem a clear connexion between the appearance of jaundice in six out of seven men receiving neorsphenamine and the simultaneous appearance of cases of infective hepatitis in the rest of the unit. It supports the view that jaundice occurring during the course of such treatment may be due to infection with the virus responsible for infective hepatitis and that patients receiving neorsphenamine are in fact much more susceptible to this infection than normal people. Further, if it is accepted that these six cases in the neorsphenamine patients were really cases of infective hepatitis it suggests that the proportion of the unit actually exposed to infection by the virus must have been high (since in this group with increased susceptibility to the disease six out of seven go down). However, in the rest of the unit 12 cases were all that occurred among 900 men, indicating that in normal people only a small proportion (about 1%) among those exposed to infection by the virus of infective hepatitis actually contract the disease.

## Reviews

### ENDOCRINOLOGY

*The Diseases of the Endocrine Glands*. By Hermann Zondek, M.D. Fourth (second English) edition. Translated by Carl Pransnitz, M.D. (Pp. 496; illustrated. 40s.) London: Edward Arnold and Co. 1944.

Prof. Zondek's book originally appeared in Germany in 1926. After he left Berlin he was first at the Jewish Hospital in Manchester and is now director of the medical section of a hospital in Jerusalem. Two English editions of this book have now appeared—in 1935 and 1944. The general scheme remains the same, but there have been extensive revisions and additions called for by fresh discoveries. He is rightly insistent that endocrinology cannot be comprehended apart from general internal medicine. A number of fundamental hypotheses, largely based on the author's personal experiences, give this book its special outlook. He is clear that not only is hormonal influence a variable quantity but that the receptivity of the tissues plays an important part in such variations. When we see a patient with general hyperthyroidism and yet with myxoedematous legs, obviously the capacity for reception of circulating thyroxin has, in that instance, varied greatly in different parts of the body. Again, functional and anatomical changes in endocrine glands should not always be regarded as the cause of disease, but in many cases as the reaction of the glands to morbid processes primarily located in other organs; as an effect rather than a cause. Hormones intensify new cellular functions which appear as evolution and differentiation proceed, but even in the most highly developed beings, however, not all of them are indispensable to life. Moreover, the endocrine system is but one link in the chain of vegetative functions of the organism. Failure to realize this leads to a dangerous over-estimation of the importance of the hormonal factors.

From such a sane and balanced foundation a sounder superstructure can be safely built rather than on the airy speculations too rife in the recent past. It is noteworthy, in view of the present interest taken in disturbance of the water-salt balance as a cause of obesity, that the author has for years called attention to this type under the title of cerebro-pituitary-peripheral obesity. The book is copiously illustrated and is practical in form throughout. We can repeat the cordial welcome which we extended to the former English edition.

### TRANSURETHRAL PROSTATECTOMY

*Transurethral Prostatectomy*. By Reed M. Nesbit, M.D., F.A.C.S. A Chapter on the Vascular Supply of the Prostate Gland. By Rubin H. Flocks, M.D. (Pp. 192; illustrated. 57 5s or 41s.) Springfield and Baltimore: Charles C. Thomas. London: Baillière, Tindall and Cox.

There is no operation in surgery the success of which is more determined by the skill and the experience of the operator than that of transurethral prostatectomy. Formerly there were few reliable descriptions in urological literature of the technique to be employed in carrying out this difficult procedure, and the beginner was compelled to acquire his own technique by the painful process of trial and error. Fortunately this defect is now being remedied, and the operator with little personal experience of transurethral resection is able to obtain guidance from those who are experts. Dr. Nesbit gives a detailed and very clear description of the particular technique which he employs in the Michigan School of Urology. He does not claim that this is the only method of performing this operation, for he believes that the existence of different methods is both logical and desirable. All that he claims is that it is the method which in his hands has proved the most serviceable.

The material in this book is arranged in four sections. The first lays down the principles and various techniques of prostatic resection, the second contains the author's appraisal of the place of resection in prostatic surgery, the third provides a history of the operation, and the fourth gives an excellent bibliography of the subject. One of the distinguishing features of the author's own technique is that instead of beginning his resection in the mid-posterior line, as do many resectionists, he starts work anteriorly at eleven and one o'clock on the lateral lobes. He does so for two reasons: first, because in

this position there is less prostatic tissue and the landmark of the internal sphincter can more easily be disclosed; and, secondly, because if the first incision is made in the mid-posterior line the tissues mobilize and retract from view in an upward direction. His description of the three stages of his operation—the intravesical, the subvesical, and the apical, the last of which includes the prostatic tissue lying adjacent to the external sphincter—is an exceedingly clear one, and by thus subdividing it he ensures that obstructing tissue is completely removed. That the technique which he describes ensures thoroughness is confirmed by the fact that in only 5% of his cases has a resection to be repeated. Although the reviewer's own technique is a different one, he can appreciate the value of the method described in this book. It can be confidently recommended to all who are interested in this important subject.

### THE POLISH MEDICAL SCHOOL, AT EDINBURGH

*Polish School of Medicine at the University of Edinburgh. (Pp. 72. No price given.)* Edinburgh: Oliver and Boyd Ltd.

Not often in these straitened times does a book come to the reviewer's table in handsome embossed binding and with four-and-twenty full-page illustrations on art paper. We are far from saying that the formation in 1941 of the Polish School of Medicine at the University of Edinburgh was not worthy of such a commemoration. The event was one of much importance; in a sense it made academic history, for there is said to be no previous record of any State setting up its own university with its own professors lecturing to its own students in their native tongue on foreign soil and as part of a foreign seat of learning. Possibly even the slighter circumstances connected with such an inauguration are worthy of permanent record, even to facsimile reproductions, again on art paper, of the preliminary correspondence and of the programmes of the ceremony. But we wish that in this sumptuous setting some account might have been given of the past history of Polish medicine or of the six universities of Poland, whose names and coats of arms are inscribed on the cover. As it is, the record, most artistically produced, is only an extended newspaper narrative of the proceedings and a statement of the activity of the first and second academic years. In the second year 113 students matriculated, of whom 33 were women.

This publication gives us the opportunity to congratulate again both the University of Edinburgh and the Polish Government on the continuance of Polish medical science in the sore days of exile. The Edinburgh Medical School itself must experience gratification at this new link with the Continent of Europe, which has been shaped in the fire of Scottish generosity.

### Notes on Books

A second edition of *The Vitamins: A General Survey for the Practising Pharmacist* has been published by the Pharmaceutical Society of Great Britain at 2s. 6d. The material of this book is based on a series of articles which appeared in the *Pharmaceutical Journal* in 1938-9, but it has been thoroughly revised and much of it rewritten. It contains chapters on terminology, units of measurement, chemical and physical properties, vitamin values of common foods, requirements of human subjects, effects of overdosage, physiological action and signs of deficiency, pharmaceutical preparations, and the potency of commercial preparations (196 of them!). It contains also a list of 10 "books to read," and one of 22 "makers and suppliers" (with addresses) of the commercial preparations. There is a useful index. The size of the book (5 in. by 7½ in.) is much more convenient than that of the first edition, but it is still bound only in paper. It has been very carefully written and should prove of great value to medical practitioners as well as pharmacists who want information in a compact and readily available form.

A third edition of the pamphlet *War-Time Information for Pharmacists*, compiled by the *Pharmaceutical Journal*, is published by the Pharmaceutical Press, 17, Bloomsbury Square, W.C.1, at 1s. 6d. post free. As before, the contents are arranged in the alphabetical order of their headings, and there is a convenient list of addresses at the end. The information has been brought up to date, and some of it will be useful to general practitioners as well as to pharmacists.

*A Book of Food*, by S. P. B. MAIS, is published by Transatlantic Arts Ltd. at 4s. 6d. This is a first book on food written for children, showing how it is grown, where it comes from, and which foods are best for growth and health. Illustrations fill the larger part of each page; the statements in the text are simply made and accurate, and there are only two pages at the end that the children for whom the book is written may find dull. Intelligent children may be stimulated by it sufficiently to ask questions which their parents cannot answer.

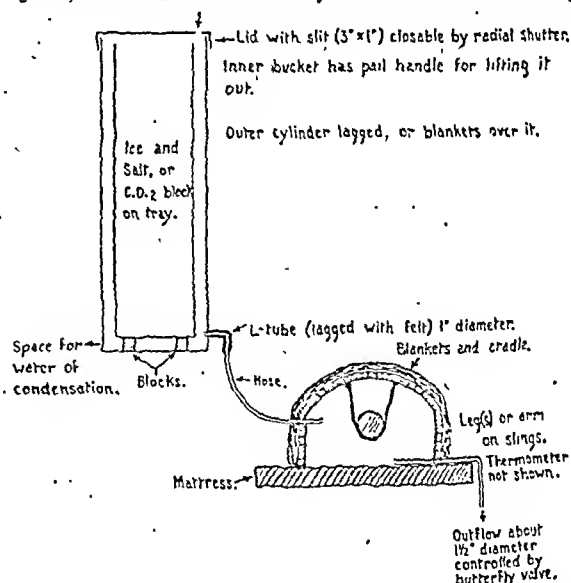

## Preparations and Appliances

### TREATMENT BY COLD AIR: A GRAVITY METHOD

Dr. FRANK C. EVE, F.R.C.P., writes from Hull:

Treatment by dry cold is now advised when circulation is blocked by frost-bite, trench foot, traumatic arterial spasm, arterial embolism, etc., in order that the limb may not decompose before its circulation is restored. In the *Journal* of Feb. 12 Capts. Bigelow and Lanyon, R.A.M.C., describe an ingenious but complicated apparatus for this purpose. May I suggest a simpler substitute, working by gravity? Although cases of this kind are not in my province as a physician, I had an analogous apparatus made for treating pneumonias in children by "Alpine air," from which the moisture and impurities had been frozen out. It worked all right but soon became superfluous, because sulphapyridine came into use, with a run of 52 cases without a death.

The apparatus was merely a metal cylinder 2½ ft. high and 1 ft. diameter (from memory) containing ice and salt. This was enclosed in a similar cylinder 2 in. wider. The annular space between them was occupied by a long flange (not shown in diagram) soldered to the inner cylinder in the form of a spiral

plane (at about 40 degrees). The heavy cold air glided down this and emerged through a spout, falling in a gentle stream on the child's face—walled round by a folded bath-towel into a sort of pond of cold pure air.

It seems probable that this simple gravity method would suffice to keep a bloodless limb cold enough if it was slung under a cradle well insulated by blankets and a mackintosh. If found adequate this would be better than the proposed method by brine electrically refrigerated pumped through narrow (blockable) tubes circulating round a metal chamber. A tinsmith made my apparatus very cheaply; possibly two tall iron fire-buckets separated by coils of barbed wire might do at a pinch.

If solid CO<sub>2</sub> were available (as from undertakers or ice-cream makers) the same device should work even better. Or it could be made as quite a small fixture just above the cradle—merely a felt-covered tin with a tray of wire mesh to hold the standard block of CO<sub>2</sub> and an exit tube below serving also as a trap for condensed water. Another larger exit tube would lead the air and CO<sub>2</sub> harmlessly away from the cradle (and patient) to the floor. A slit in the lid would regulate both flow and temperature. These devices (when once tried out) could soon be improvised; and where there is frost-bite, it will be available.

# IODATOL

Trade Mark

*Iodised Oil B.P.  
containing 40% combined Iodine*

Iodatol is identical with the iodised oil formerly imported from the Continent under a proprietary name. It is the ideal X-ray contrast medium for the exploration of the bronchial tree, female genital tract, spinal column, salivary glands, paranasal sinuses, abscesses, fistulae and similar body cavities.

Literature is available on the use of Iodatol generally, and its use in gynaecology particularly.

*Iodatol is issued in bottles of 20 c.c.*

X-Ray/E/22

TRADE MARK 'ACETYLARSAN' BRAND  
diethylamine acetarsol solution  
an efficient intramuscular arsenical

'Acetylarsan' brand diethylamine acetarsol is a ready prepared solution of a pentavalent arsenical for the treatment of syphilis by intramuscular or deep subcutaneous injection. By these routes it is much better tolerated locally than are the trivalent arsenicals.

Its administration in appropriate dosage has been reported to lead to the disappearance of spirochaetes from the chancre in six to twenty-

four hours, the healing of the primary lesion within twelve days, and of mucous patches of the tongue and lips within ten days.

#### Supplies:

Adults (25.60 per cent. solution)  
10 x 3 c.c. ampoules 10s. 6d.  
and in boxes of 50 x 3 c.c., 1 x 5 c.c. and 50 x 5 c.c. ampoules  
Children (9.40 per cent. solution)  
10 x 2 c.c. ampoules 7s. 6d.  
and in boxes of 50 x 2 c.c. ampoules

Obtainable from your usual supplier at the above prices subject to the usual discounts and purchase tax

# Insulin A.B.

Over 20 years ago Allen & Hanburys Ltd. and The British Drug Houses Ltd. decided to pool their resources in regard to the manufacture of Insulin. The object was to make available as quickly as possible, a supply of Insulin in this country.

Insulin A.B. was the result.

It was one of the first British Insulins to be offered commercially to the medical profession and was sold in 5 c.c. vials (20 units per c.c.) at 25/- per vial.

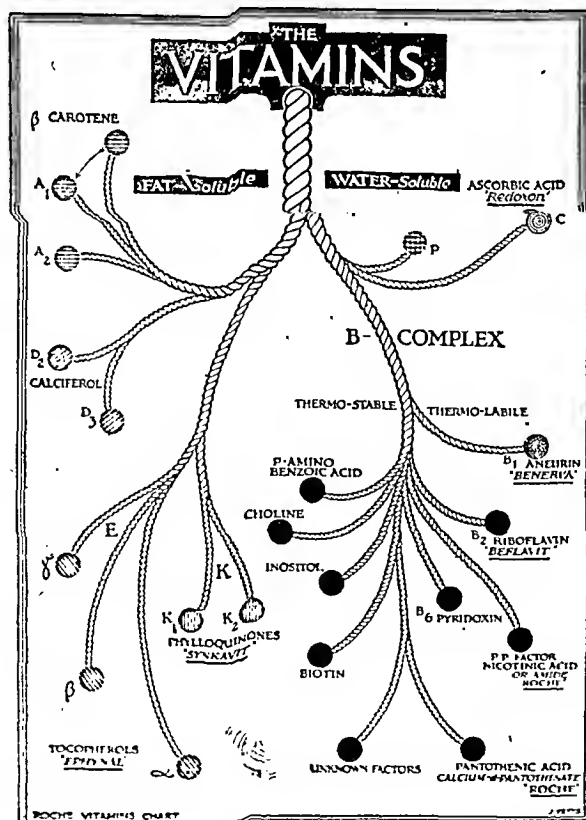

Through constant research and improvement in the manufacturing process, the same high quality and quantity of Insulin A.B. is now sold at 1/3.

Insulin A.B. conforms to every test and combines the high reputations of two famous British manufacturing houses.

Joint Licensees and Manufacturers:

ALLEN & HANBURYS LTD.

THE BRITISH DRUG HOUSES LTD.

## 'Roche' Vitamin Preparations

Since the first synthetic vitamin, namely vitamin C, was introduced ten years ago as 'Redoxon' laevo-Ascorbic Acid, Roche Products Limited have directed ever-increasing care to the manufacture of other vitamins, notably 'Benerva'  $B_1$  (aneurin) and 'Beflavit'  $B_2$  (riboflavin). Oil-soluble vitamins are also made by Roche: 'Ephynal' Vitamin E and 'Synkavit' vitamin K analogue.

## BEFORE NEGOTIATIONS BEGIN

At the meeting of the B.M.A. Council last week a number of important decisions were taken and two highly significant documents were placed before it, the one for information and the other for discussion as the basis of a report of the Council to the Representative Body. As we believe that these two documents are at the moment of supreme interest and importance to the whole profession, including those who are not members of the Association, we have printed them in the opening pages of what is principally a scientific, medical newspaper. In normal times many medical men are for the most part uninterested in medical politics, being more concerned with applying their science and art in the treatment of the sick, for this is their profession. To-day, however, every medical man willy-nilly must become a medical politician, and perhaps a very big majority in the profession are now thinking in terms of medical politics for the first time. Many are in the unfortunate position of having to try to speak a language with only an elementary knowledge of its grammar, and therefore they tend to look with some suspicion upon the grammarians. These are the people who, in times of stress such as the present, tend to accuse the B.M.A. of "doing nothing," of "not giving a lead," or, even worse, of carrying on secret negotiations and discussions with the Ministry of Health. Such accusations—and they are being made—are unjust and baseless. Those who at this late moment wish to learn the ABC of medical politics might catch up a little bit by reading two documents—one the B.M.A.'s proposals for a General Medical Service for the Nation,<sup>1</sup> available as a grey book, and the other the Draft Interim Report of the Medical Planning Commission, published only two years ago.<sup>2</sup> This draft report was the result of co-operative work between the Royal Colleges, the Association, the Society of Medical Officers of Health, and the Medical Women's Federation. The appearance of the Beveridge report, with its serious medical implications, interfered with the continued deliberations of the Medical Planning Commission, and hence postponed indefinitely the preparation and publication of a final report. Out of the Commission came a smaller committee representing the same medical interests. This Representative Committee entered into discussions with the Ministry of Health, but without any power of negotiation. Apparently many voices have uttered the fantastic sugges-

tion that the Representative Committee was responsible for the White Paper. If the Representative Committee can be said to have had any influence at all it was in preventing the Government from drafting a document plainly advocating a whole-time salaried service, and leaving little or no room for further discussion on this point. Of the emotional cross-currents in the life of the profession to-day, the strongest is suspicion. We may be sure that those who have not really at heart the interests of the medical profession will take full advantage of the suspicions that prevail, and use them to promote disunity among us at a time when unity is the one indispensable weapon needed by the profession's negotiators with the Government in the days to come. As doctors we boast proudly of our individualism, but this is a characteristic that can become so hypertrophied as to be as dangerous to the profession as its tooth was to the sabre-toothed tiger. It is as well to remember that there are now 46,195 members of the B.M.A., and that there cannot be 46,195 separate plans for reorganizing the medical profession.

The report at page 643 of our current issue marks both the end of one phase and the starting-point for the next. The Representative Committee is now dissolved. A negotiating body is to be set up, to begin work after July. This will be composed of 30 members: 16 of these are to be appointed by the British Medical Association (8 by the Council and 8 by the Representative Body at its meeting in July); 3 are to be appointed by the Royal College of Physicians, 3 by the Royal College of Surgeons, and 2 by the Royal College of Obstetricians and Gynaecologists; 2 are to be appointed by the Society of Medical Officers of Health, 1 by the Medical Women's Federation, and others by the Royal Scottish Medical Corporations. In so far as it is possible to devise any way of electing representatives that would satisfy most people at any one moment, the method proposed and the distribution of representatives would seem to be the fairest way of ensuring that our negotiators can speak with one voice when it comes to the hard weeks of negotiation that lie ahead. It can, however, speak with this one voice only if it is trusted and not suspected by individual doctors or groups of doctors. The Representative Committee at its last meeting, and the Council at its meeting on May 3, decided to hold no more discussions with the Minister or with the Ministry of Health until the negotiating body is set up at the Annual Representative Meeting in July. The last communication with the Minister of Health was to put before him certain written questions with a request that written answers should be given to them. These questions and the answers returned by the Minister are set out in full, with no omissions, as the second "contribution" in the opening pages of this week's *Journal*.

In the fallow period between now and the moment when negotiations begin it is hoped that doctors both individually and in groups will give as much time as they can spare from their daily work to an intensive study of the White Paper and to any other published matter that has a bearing on it, and more especially to the report of the Council to the Representative Body. It is most likely that some sections of the Press will isolate for quotation parts of the report that will help them to prove whatever mis-

<sup>1</sup> *British Medical Journal Supplement*, 1938, 1, 253.<sup>2</sup> *Ibid.*, 1942, 1, 743.

leading case they may wish to present. In spite of much admirable educative work that has been done over the past year or so by the Association, the public is still most ill informed about medical matters, and still fails to understand why we as a profession attach importance to certain fundamental aspects of our work. It would be a mistake to think that the public is generally sympathetic to the medical profession as a whole. The most obvious form of misrepresentation is to depict doctors as generally opposed to reform because of their supposed financial interests in the present way of giving personal medical service to the people of this country. Like most other workers, doctors still believe that a labourer is worthy of his hire, and see no reason to be ashamed of working for hire. Many people think, speak, and write as if the medical profession should turn itself into a philanthropic institution; hence the popularity of the slogan "Free treatment for all."

Out of many admirable statements in the Council's report we would pick upon the following as summing up succinctly the attitude of most medical men to reform: "To agree upon the objects of national reconstruction in the field of health is not necessarily to approve the methods or the time-table proposed." There should be no need to recapitulate in these columns the successive steps that have been taken by the B.M.A. to bring about medical reform during the past 20 or 30 years. During this period it has found both Government and public completely unresponsive to every demand for reform made, reforms that had the double virtue of being in the interests of the public and not contrary to the interests of the majority of the medical profession. Both publicly and privately, doctors should make it clear where they take their stand—and this is not against reform, which they recognize to be necessary, but against certain specific proposals in the White Paper, and against the motives which appear to lie behind these. There is in fact a flat contradiction between the excellent principles long accepted by medical men, and printed at page 47 of the White Paper, and the proposals contained in it. The medical profession is, too, opposed to the time chosen to introduce these reforms. Again it should be clear that it favours the preparation of plans and the discussion of ways and means of carrying out these plans, so that it may lay them before the now large numbers of medical men engaged in the Forces who will carry on the work of the doctor in the two or three decades after this war. To introduce legislation in wartime, with the younger generation of doctors away, would seem to betray the promise made by the Prime Minister not to legislate during the war on controversial matters. Paragraph 15 of the Council's report makes this moderate statement: "It [the B.M.A.] is inclined to suspect that the inspiration of the Government's document is political rather than medical." Many sober observers go further than this rightly cautious utterance. It is because the profession suspects that the White Paper is the result of political bargaining that it distrusts the proposals made, couched in however fair language. If, as we understand, the White Paper is in essence a Cabinet document, it would seem that the right hand of the Cabinet was unaware of what its left hand was up to.

From the point of view of the general practitioner the key proposal of the White Paper is the establishment of health centres to be built, owned, and administered by the major local authorities—namely, the county councils and the county borough councils. For rewarding the staff of these centres the Government favours payment by salary. The practitioner will enter into contract with the local authority and the Central Medical Board. If in fact such a proposal is accepted and acted on, then it is difficult to see any other fate for the future general practitioner than that of a whole-time salaried servant of the State. The threat to the other key structure in our medical services is the threat to the voluntary hospitals. This threat is aimed at them through the agency of the proposed joint authority, through the drying up of voluntary contributions, and through the suggestion that, if the Government pays in full for the services of the voluntary hospitals, this will necessarily involve loss of autonomy and status. The real issue, in fact, is not whether money for health services should be collected in this way or that way, or should be distributed to those who render the services in the form of fees or of salary, but whether the medical profession is to be socialized: turned, in other words, into a body of men deprived of that freedom of thought and action which over the centuries has made it possible to substitute for the magical incantations and practices of the whole-time employee of the Temple the rational thought and free practice of contemporary medicine. When, in addition to this, the profession sees a Government so frightened of the power of local authorities, so hampered by the interdepartmental jealousies of Government Departments, as to leave these unsound dwellings untouched, then as a profession we cannot help but suspect its motives. The skeleton structure into which the body of medicine is to be moulded is the skeleton not of a developed adult but of a disjointed puppet. Except for a vocal minority of doctors grouped round a party political flag, by far the greater part of the profession is rigidly opposed to a whole-time State salaried medical service, and it is upon this one issue that opposition must be unshakably offered in the coming months.

To resist all proposals moving in the direction of a whole-time salaried State medical service must not be taken as opposition to the White Paper as a whole, nor must it mean a refusal to negotiate, as some doctors apparently would so like to refuse. It is necessary to be clear-headed in opposition, and whole-hearted in co-operation in reforms agreed to be necessary. Some of these reforms are put forward in the second half of the Council's report to the Representative Body of the British Medical Association, in paragraph 38 onwards, in positive proposals that crystallize the results of the deliberations of the Council's Standing Committees.

The profession can approach the coming negotiations at least with the knowledge that in the present Minister it has to do with a man who has shown himself sympathetic to the professional point of view. It will be able to enter negotiations fully conscious of a proud record of service, and fully aware that time and tradition have given it a stake in the country to which it is justifiably entitled and which in equity it is entitled to defend.

## REPORT ON MEDICAL EDUCATION

War is the supreme test of a nation's health services, but in this war the verdict has been something of a paradox. On the one hand the national health has shown a surprising resilience, and statistics of sickness have improved. On the other hand there has been wide concern at the poor state of health revealed by surveys and by the mass evacuations of 1939 and 1940. The Peckham experiment,<sup>1</sup> for example, finds less than 10% of its subjects without some disorder of health. Evacuation focused the attention of the country on the frequency of infestation by parasites, skin diseases, and defects of the teeth, eyes, ears, nose, and throat in city children. Much of this ill health demands as a remedy the provision of better homes, food, and work for the people, but much of it demands medical attention which is not now available. There is a shortage of practitioners, specialists, and pathologists. The war has also revealed the importance of newer branches of medicine, such as industrial medicine, psychology, applied physiology, and nutrition, which are still imperfectly recruited in this country. There is a demand that more money should be spent on research, and in particular that the deficiencies of this country in applied pharmacology and chemotherapy should be repaired. High-ranking officers in the medical services of the armed Forces and of industry complain that the newly qualified practitioner is lacking in adaptability to unrehearsed situations and in knowledge of the preservation of the health of the mind and body. On all sides, therefore, there is a demand for more doctors and better doctors. Nevertheless, it would be a mistake to imply, as some recent newspaper headlines have, that the medical student of to-day has fallen from grace or actually deteriorated. Most teachers would agree that medical students are at the very lowest reckoning a good sample of our university population. Our only doubt about them had been whether they had the stamina of their forbears, and this has been abundantly proved by the war. The verdict on the medical student must be very much the same as that on the nation's health. He has shown a surprising resilience in the face of a continual overloading of the medical curriculum, but there are grounds for dissatisfaction with both the quality of the students entering the medical schools, and the training they receive there.

Medical education, then, is a subject of interest to the whole profession, and for this reason it is to be hoped that the report on medical education by the Planning Committee of the Royal College of Physicians of London will be widely read. The committee is to be congratulated on having produced an extremely able report, which shows a notable advance on documents of this kind that have appeared in the past. The two previous reports on social and preventive medicine, and on psychological medicine, which the College published last year, were widely criticized as examples of the old pipe-line theory of education, in which the student is regarded as a passive and distensible receptacle into which more and more facts are poured. In the present report the College has appreciated that the problems of medical education cannot be solved by the

simple process of addition, and has addressed itself to the more difficult process of integration. To obtain good students of medicine the profession must be made attractive, and the students must be selected by some better criterion than ability to pay. The committee proposes that university fees should be abolished and maintenance grants paid to students in need. This is not as revolutionary as it sounds, for students' fees only pay a third of the cost of their education, and in the U.S.A. at the present time all medical students are in uniform and in receipt of army pay. It does, nevertheless, entail very careful choice of students. The committee deprecates the use of examinations and scholarships for this purpose, as they lead to premature specialization at school and often produce an undesirable kind of candidate. It emphasizes the importance of character and personality and suggests selection on the basis of these qualities and the school record. The selection of anything from 2,500 to 5,000 students a year from a considerably larger group of applicants by the method of the interview seems to us a more formidable undertaking than the committee appreciates. It would hardly be possible without psychological tests similar to those used for the selection of officers in the Army. Intelligence is not less important than character and personality, and tests of intelligence could be used to sift the applicants. It is true that stupid students often make successful doctors, but it is doubtful whether they ever make good doctors.

The body of the committee's report is informed by a number of general ideas. It is fundamental that the student should be taught method and principle rather than facts. Only in this way can the university provide the doctor with a discipline and an instrument which will allow him to adapt himself to the rapid advances of scientific knowledge and to maintain a progressive self-education. There must be better co-ordination of studies, both vertical and horizontal: vertical between the three divisions of pre-medical, preclinical, and clinical studies; and horizontal within each division, as between anatomy, physiology, and biochemistry, or between preliminary medicine, surgery, and pathology. Much of the factual material with which the present curriculum is weighted should be postponed to the stage of postgraduate education, when the doctor has decided on the career he will choose in the wide field of medicine. In emphasizing the importance of postgraduate studies, when the student has gained some practical familiarity with his material, and when his studies are inspired by the incentive of strong interest, the committee is in line with Sir Richard Livingstone, who has called this the vital principle of adult education.<sup>2</sup> Finally the committee emphasizes that medical education as we see it to-day is formed by the convergence of two streams: the one rising from the medical schools founded in the hospitals, the other from the universities; the one vocational, the other educational: the one representing apprenticeship, and the other academic study. The waters of both these tributaries are needed to maintain a high level of medical education, and in the future we shall probably gain a clearer conception of the contributions that can be made by the part-time clinical teacher with his experience of

<sup>1</sup> Pearce, I. H., and Crocker, L. H., *The Peckham Experiment*, London, 1941.

<sup>2</sup> Livingstone, R., *The Future in Education*, Cambridge, 1941.

practice, and the whole-time clinical teacher with his opportunity for organized teaching and research. While the student is untrained in clinical methods and clinical science, it is wasteful and confusing to put him to work in a ward where the main preoccupation is the treatment of the sick and where the examples of disease presented to him are complex and unrelated. Only the senior student has the equipment to profit by this kind of experience and teaching. Both the introductory clinical course and the first ward-l clerkships must take the form of organized teaching in which cases suitable for progressive instruction are taken from a pool and in which clinical studies are correlated with preclinical studies and pathology. At the end of his undergraduate clinical course, which should be contained within three years as at present, the duty of the examiners will be to ensure that the student has learnt methods and principles—that he has, in other words, been educated—and on this examination the student will obtain his degree or medical qualification. It will still be necessary to ensure that he is safe to practise, and to meet this need the committee recommends a compulsory year of paid resident house appointments in recognized hospitals, at the end of which the student would be examined for his practical or vocational ability and would receive his licence to practise independently.

There is much in this interesting report which we have not space to consider now. It is important to point out that it means a great increase in the routine duties of teachers, preclinical and clinical, whole-time and part-time, all of whom must be more adequately paid than in the past. Reforms in medical education will come at a time when the medical schools are also playing their part in the postgraduate education of the young doctors now in the armed Forces. Selection of students, co-ordination of studies, teaching by the seminar and the tutorial method, organization and working up of cases for progressive instruction in clinical science—all these are time-consuming. Most of our standard textbooks must go on the reference shelf, where they properly belong, and new textbooks must be written and practical courses prepared which are directed to the study of method and principle. The techniques of the instructional film and the synthetic training of the Services must be incorporated in our teaching. In all this it seems to us peculiarly important to safeguard the position of the whole-time clinical teacher, on whom the work of reorganizing the approach to clinical study will chiefly fall. The preclinical teacher has the inspiration of his work. The part-time clinical teacher has the satisfaction of his practice and the associations and social prestige it brings him. Too often the whole-time clinical teacher, with his continual responsibility for care of patients, administration, and teaching, becomes degraded to the level of a hack-tutor, for whom "To-morrow and to-morrow and to-morrow. Creeps in this petty pace from day to day." The stimulating atmosphere of our teaching hospitals has depended on a blending of altruism and individual enterprise, of practice and research. Teaching, to be inspired, must be a part-time occupation which is sustained by practice or by research. For the whole-time clinical teacher this means daily leisure for study and research, the long vacation and the sabbatical year, and we should like to have seen these points rather more sharply made in the present report.

## METHYL ALCOHOL POISONING

Among the unsolved problems of the entity known as methyl alcohol poisoning the actual toxic mechanism and the selective incidence of amblyopia have hitherto taken first place. It has long been known that methyl alcohol is a comparatively weak narcotic but a strong cumulative metabolic poison, and that it produces an acidosis; but the source and nature of the acidosis have never been completely explained. Nor has it been decided whether the amblyopia bears any direct relation to the acidosis, or why the toxic action should be selectively exerted upon either the optic nerve or the ganglion cells of the retina. Answers to some of these questions have now been provided by an investigation<sup>1</sup> of 16 cases of methyl alcohol poisoning, and suggestions for treatment are based on the knowledge obtained. The symptoms in these cases undoubtedly resembled the clinical manifestations of acidosis—anorexia, nausea, vomiting, dyspnoea, drowsiness, and coma—and their severity was commensurate with the fall in the alkali reserve, which was 9 vols. per cent. in a very acute case as compared with 33.8 in a case with only mild general disturbance. The degree of amblyopia also appeared to depend on the degree and duration of the acidosis. On the basis of these facts and the actual demonstration in two cases of an increase in the lactic acid concentration of the blood, a hypothesis of the true nature of the acidosis is advanced which embodies some of the conflicting elements of the long controversy on formic acid versus formaldehyde as the specifically harmful decomposition product of methyl alcohol. It is suggested that the factor primarily responsible for the acidosis is formic acid, which enters into a complex compound with the iron of the respiratory enzyme, thus inhibiting oxidation and causing an increase of lactic acid. Correlation between the degree of acidosis and the severity of amblyopia is explained by the high consumption of oxygen by the retina (demonstrated by Warburg) and its consequently high susceptibility to defective oxygenation, this being followed by degenerative changes in the retinal cells. Since exposure to strong light increases the call on oxidation, this might be expected—as was indeed found to be the case—to increase the severity of the amblyopia. The secondary later deterioration of vision characteristic of methyl alcohol poisoning is attributed to subsequent atrophy of severely injured retinal blood vessels.

A rather surprising feature of the course of the poisoning in some of the cases was the favourable action of ethyl alcohol. Those patients who had drunk large quantities of port, gin, or beer either before or after the methyl alcohol showed no permanent ill effects. This, it is suggested, is due to the capacity of ethyl alcohol to displace methyl alcohol from its intracellular attachments, thereby checking its oxidation to formic acid. The heroic recommendation that ethyl alcohol shall be drunk repeatedly during the first few days after the consumption of much methyl alcohol is therefore included in the treatment advised. Other measures include the rapid correction of acidosis by intravenous injection of isotonic (1.3%) solution of sodium bicarbonate; liberal flushing with fluid; protection from exposure to light; and avoidance of all stimulants of metabolism, such as exercise, hot baths, and thyroid extract.

Prof. E. D. Adrian, O.M., F.R.S., will give the Bertram Louis Abrahams Lecture at the Royal College of Physicians of London on Thursday, June 8, at 4.30 p.m. Subject: "Localization in the Cerebrum and Cerebellum."

## SOME IMPRESSIONS OF SLOW STARVATION IN CHINA

BY

H. T. LAYCOCK, F.R.C.S.

The clinical picture described below became painfully familiar during a little more than a year (Oct., 1942, to Nov., 1943) spent in medical work in South Kwangtung, China. These notes are based on observation of hundreds of starving people attending at an out-patient clinic, seen scavenging in the streets, lying dead or dying on the sides of country roads, and visited in a large camp for refugees. The syndrome exhibited by these people was very uniform, and as it added some details to the usual textbook account of "wet beriberi" I thought a description of it might be worth recording.

### Japanese Technique of "Repatriation"

More than 90% of the cases were refugees who had come, in some cases voluntarily and in others against their will, from occupied to "free" China. The remainder were nearly all Chinese soldiers, many of them as a matter of fact recently recruited from among the refugees. The voluntary refugees, finding life under the Japanese intolerable, had migrated to seek their fortune inland. Unfortunately many of them had been left destitute by robbers.

The involuntary refugees were what the Japanese call "repatriates." In spite of glowing descriptions in their newspapers the Japanese technique of repatriation, as applied to the Chinese, is apparently as follows. Without warning some hundreds of harmless pedestrians, hawkers, and beggars are rounded up in the streets of an occupied city. There is certainly a tendency to choose the less desirable elements in the community, but this choice is by no means a careful one. The victims, of all ages and both sexes, are then systematically starved in one of the worst sort of concentration camps. The daily ration consists of rice gruel cooked with bicarbonate of soda (in order to economize on firewood) which is served without salt, flavouring, or other addition. It would seem possible that the constant adding of soda to the food in this way might produce a chronic alkalosis with renal damage of significance in relation to subsequent oedema. In many cases these people have told me that they were transferred from a normal home life, where the diet was adequate if not abundant, to a squalid and pestilential camp, where they were slowly starved and denied all medical attention and where the death rate was enormous.

From the camp victims considered sufficiently weakened are transported in overcrowded junks to the coast of free China, where those that have not died on the way are left, totally destitute, to their own resources—to the intense annoyance of the local residents. The ones who are too weak to walk remain where they are landed until they starve. Many of them try to prolong their sufferings by consuming inedible or semi-edible substances. I have been shown hard woody roots and have been told that after prolonged soaking these can be cooked into something that can be swallowed. I have also seen a dark green powder, prepared by drying and pounding certain leaves, and have been assured that it can be used as a substitute for flour. The refugees also steal and eat unripe rice, a crime for which the penalty is death. In our local refugee camp the heaps of banana skins and mango stones, scavenged in the streets for use as food, give eloquent witness to the intensity of their hunger. I am also convinced from the evidence of eye-witnesses that the flesh cut from corpses is used as food. Why more of these unfortunate people do not give up the unequal struggle and find an easy way out in suicide I do not know. Certainly very few of them seem to make the attempt. Instead they struggle inland with a frantic desperation of which one is forcibly reminded by seeing the deep ulcers on the buttocks of people too weak to walk who have struggled across the country in a sitting posture.

### Hunger Oedema and Ulceration

Clinically the most conspicuous feature in these cases was the widespread oedema, which first appeared on the dorsal aspect of the feet. These became more and more swollen until the skin was tightly stretched and assumed a peculiar bluish transparency. Later it actually gave way under tension, and multiple fissures appeared from which there was usually a copious serous discharge. These fissures were readily infected and deep gangrenous ulcers arose in them in neglected cases. Ulcers on the dorsal aspect of the feet were a common and characteristic finding. Often they arose spontaneously, but many were produced artificially by misguided attempts to reduce the oedema with filthy and irritant applications. The victim well realized that oedema of the feet was the first of a series

of most unpleasant symptoms. One soldier had applied a dark paste made from pounded leaves to the upper surface of one foot to reduce the swelling. I do not know what the chemical composition of this paste was; its effect was like that of strong caustic potash. There was an area 6 in. by 3½ in. covering the foot dorsally and extending above the malleoli. This was greenish white in colour and sodden like damp blotting-paper. In a few days it separated as a thick slough, leaving a deep and painful ulcer. The malleoli in this and similar cases retained islands of skin over them, presumably because the application had been put on thinly over the bony points. The man said he realized that swelling of the feet was a serious condition and he had used a herbalist's remedy. I was surprised to find that he expected an ulcer to form, under the delusion that this was part of the cure. However, he found the process so painful that he vowed he would never use the method again or recommend it to his friends. On a normal diet and with the daily use of antiseptic dressings this ulcer healed so rapidly that the skin grafting which I at first thought of seemed superfluous.

Another soldier had bilateral ulcers produced in the same way, but here there was a gangrenous infection, the edges of the ulcers were undermined and purple in colour, and there were hemorrhagic blisters higher up the legs. I felt obliged to do an amputation, but the patient did not survive. These dorsal foot ulcers commonly involve the extensor tendons, which are seen running across them as white sloughing strands. When the tendons have been involved in this way, and healing has occurred later, there is usually an extensor contracture, involving particularly the fourth and fifth toes, with the production of calcaneus and valgus deformities which are sometimes severe and very crippling.

Further up the leg the oedema distends the skin, and over the lower leg especially this has often a high glaze upon it. The disappearance of this glazed look was the first sign that oedema was subsiding. The whole limb up to the groin was sometimes grossly oedematous, but often the oedema stopped abruptly above the lower third of the thigh. I saw cases in which oedema in the popliteal fossae prevented extension of the knees and the patient was obliged to walk with the knees flexed. Under treatment the oedema disappeared from above downwards, persisting longest in the feet, and when it had gone the emaciation was often so extreme that whole groups of muscles seemed to have disappeared.

The external genitalia were early affected by the oedema, a symptom which seems to upset Chinese patients very much. A distressing eczema of the scrotum was also very common. There was pitting oedema over the trunk and in the arms, it was the backs of the hands that were earliest and most affected.

The face was often grossly oedematous, with the eyes completely closed. There was a strong tendency for the oedema to shift with gravity, and the whole appearance of the face would alter over night. Particularly in cases where the oedema had partially subsided the whole face seemed to sag, the swelling disappearing last from the lower part of the cheeks. The corners of the mouth drooped and unnatural creases appeared round the eyes and radiated from the alae nasi. These creases did not so much add expression to the face, which was toneless and gloomy, but rather added a bizarre touch which was quite repulsive.

The facies was further altered by the presence of dark pigmentation not strictly limited, as in pellagra, to areas exposed to the sun. The hair was dry and disorderly with a tendency to stand on end. The loss of the normal silky lustre of Chinese hair in someone who was seen before and after several months of slow starvation was quite striking. The tongue was variable, often clean and moist. In a minority of cases it was glazed and vermillion in colour. Oral sepsis was common and I often saw a thrush-like lesion on the soft palate.

### Abdominal and other Complications

Scurvy was conspicuous by its absence. Even where oedema was extreme serous effusions were quite infrequent, though I saw a few cases complicated by ascites. The musculature of the abdominal wall was toneless, and flaccid distension was the rule. Unless there was some marked oedema of the skin over the abdomen visible peristalsis, of small intestinal type, was a common clinical finding. The abdominal distension was often associated with a small umbilical hernia or with a "weeping" eczematous lesion of the umbilicus. There was very commonly watery diarrhoea and a tendency to pass any food taken unaltered in the stools. It was difficult to persuade many of these cases to eat, because they seemed to have lost all interest in food. They were very prone to contract bacillary dysentery, and any such bowel infection in a convalescent case usually caused a relapse of the oedema.

Many of them complained of cough and produced a white frothy sputum, which I took to be due to oedema of the lungs. Other pulmonary complications were uncommon. The heart was sometimes moderately enlarged and the heart sounds diminished in volume and with a tendency to "tick-tack" rhythm, but I saw so few cases

with the signs of congestive failure that I felt convinced cardiac failure could have little to do with causing the oedema.

A more or less severe secondary anaemia was invariably present and the response of this to simple iron therapy was very rapid.

As regards the nervous system I saw a few cases only of typical "dry" beriberi, but in the oedematous cases—i.e., the vast majority—nervous symptoms were not at all common. Most cases complained of "numbness" in the feet and legs, but by this they usually meant the altered sensation due to the skin being stretched by oedema. Anaesthesia to pin-prick, paraesthesiae, and paralysis were conspicuously uncommon.

A great many patients complained of night-blindness, but this was a common complaint also among people in the district, particularly soldiers, with no other symptoms. Amenorrhoea and sterility were extremely common in both refugees and village women in the district, and seemed to be invariably present in the oedematous cases.

The mental state was one of depression, which varied with the degree of oedema. This was particularly noticeable in children, who would lie curled up all day and so motionless that the oedematous skin acquired a deep impression from the straw mat beneath it. As the oedema subsided they became mentally alert again. The adult patient usually came with the fixed idea that he or she must be admitted to hospital, and would repeat the same request over and over again with tears dripping from the cheeks. Cerebration was slow and the extraction of a history very tedious. As mentioned earlier, suicide as a way of escape was quite uncommon.

The clinical course was marked by a strong tendency to relapse. The slightest intercurrent infection, usually a more or less severe enteritis, would be accompanied by a disappointing reappearance of the oedema. An alteration in the weather would cause surprising changes, and after a spell of hot damp weather was over most of the cases improved very rapidly.

#### Response to Treatment

Treatment consisted in giving a diet with a high protein content, liver, meat, fish, and soya-bean derivatives. We gave rice polishings in the form of a cake made with flour and a little baking powder and fried in peanut oil. These were very popular, especially with the children. Vitamins were given in the form of teleostol capsules and thiamine hydrochloride injections, but I didn't have enough to use them freely.

In their response to treatment patients fell into two groups. In one there was a rapid uncomplicated recovery; in the other, in which there was generally persistent albuminuria, progress was slow and laborious with disappointing relapses and a tendency to die suddenly and unexpectedly.

## MEDICAL EDUCATION

### ROYAL COLLEGE OF PHYSICIANS' REPORT

The Report on Medical Education of the Planning Committee of the Royal College of Physicians was published on May 2, and is the subject of a leader in our present issue. Limited space allows us to summarize only the main points in this highly important document, which should be carefully read by all those interested in the subject. It is divided into two parts, the first dealing with the recruitment and selection of medical students, and the second with the training of the doctor, considered under these headings: the medical curriculum as a whole; medical education; the preclinical period; the clinical period.

#### Selection of Students

In the making of a good doctor, the report observes, the intellectual and personal qualities of the student are as important as the education to which he is submitted. At present too few candidates enter medicine. An increase in the number would widen the field of selection. The doctor's way of life and his rewards must be such as to attract suitable candidates. To overcome financial obstacles which restrict the entry into medicine, the committee favours making university education entirely free, not only in medicine but in all other faculties. Free university education would bring more men into medicine and make selection easier. In assessing the suitability of a candidate two things to be taken into account are academic record and character and personality: "In the case of the doctor character is in general not less important than ability."

#### Training of a Doctor

Present defects in the average medical graduate to be attributed chiefly to training are lack of curiosity and initiative, undeveloped powers of observation, poor ability to arrange and interpret facts, lack of precision in the use of words. The training may be technically satisfactory, but is unsatisfactory as an education: "This is a matter of very great importance." The committee has therefore aimed to discover how to improve the medical course as an education without detracting from its efficiency as a technical training.

#### Curriculum as a Whole

"No other profession demands an education so complex, so rigid, and of such long duration." The curriculum grows in content, and rarely is anything taken from it. While the general structure of the curriculum is sound, and the length of training cannot be reduced, remedies must be sought under three headings: improved co-ordination, elimination of unnecessary detail, and distinction between the requirements of undergraduate and of postgraduate education.

At present there is little co-operation between the teachers of the premedical, preclinical, and clinical stages, and little between teachers of the same stage—for example, between chemist, physicist, and biologist. The committee quotes Karl Pearson's words that "the true aim of the teacher should be to impart an appreciation of method, and not a knowledge of facts." A difficulty in planning the curriculum is to cater for the variety of careers a student may ultimately follow. If all needs are to be met, there is little of organized knowledge that can safely be omitted from the curriculum. A fundamental reform, therefore, is to recognize that medical education should fall into two categories: (1) undergraduate and unspecialized, providing for doctors as a whole; and (2) postgraduate, providing for special needs. At present the curriculum to some extent combines the two. The committee observes that organized postgraduate education is as yet in its infancy. In discussing teachers and teaching methods it pleads for a wider adoption of the tutorial method, which "has long been regarded as a most valuable educational method at Oxford and Cambridge, and is becoming increasingly popular as the seminar system in the United States of America."

#### Premedical Education

Under this heading the committee stresses the importance of a general education, voicing the criticism made that specialization at school "may diminish interest in other activities of the mind, such as the history, art, and literature of ancient and modern times and of all countries." The committee believes that the student should not take the First M.B. examination before entering the university. To take it at school debars him from that general education which the committee regards as of the first importance for a doctor. It agrees that the teaching of the basic sciences should begin at school, and it believes that in the university course of general science stress should be laid upon physical chemistry and organic chemistry, and that in the biology course more stress should be laid on such biological principles as the theory of evolution, adaptation to environment, and genetics, and less time should be given to the memorizing of details of animal types.

#### Preclinical Period

The committee agrees with many others who have considered this matter that "anatomy should be more closely related to the living, and not chiefly a study of the dead." It advocates the omission of much detailed learning of topographical anatomy. It advocates what it terms the "new anatomy," and observes that this will require new dissecting manuals and new textbooks. "Physiology," it is observed, "is the natural medium for teaching the essential methods of biological science—namely, the methods of accurate measurement and experimental analysis of the factors concerned in biological phenomena." If the supply of teachers of anatomy, physiology, and biochemistry is to be maintained at a high level, then they must be paid better salaries. In urging co-ordination, the committee remarks that in one term the student may learn the structure of the alimentary tract from the anatomist, in

a second the digestion of foods from the biochemist, and in a third the movements and secretions of the gut from a physiologist. The student should be introduced to methods of examining the normal body during the pre-clinical period.

### Clinical Period

"Medical education is directed towards two objectives which may be termed educational and vocational." In the former the student is taught method, so that he can collect, analyse, and interpret facts for himself, and observe and understand what he observes. In the latter he is given such knowledge as will enable him to practise medicine on his own account. As a medical graduate on qualifying can at present assume full responsibility for taking charge of patients, then in the public interest the State must insist "that every student before qualification should acquire a basic knowledge of all branches of medicine and surgery, including the various specialties, as well as of medical jurisprudence, public health, and hygiene." This knowledge has to be acquired in three years. The absorption of "an enormous mass of facts" does not allow the student to give thought to the scientific principles underlying medicine. The predominating factor in this dilemma is the need to protect the public from the ignorance of the newly qualified; but the emphasis is on factual knowledge, and unless the student is grounded in method and principle he cannot make full use of experience in the development of judgment—"and it is on judgment that his value to the public as a doctor will chiefly depend."

### COMPULSORY RESIDENCE

The committee, therefore, proposes to divide the clinical period into two phases: (1) the undergraduate period proper, of three years, and (2) a compulsory resident year—the former to be spent mostly in training in method and principles, with an examination at the end to test the student's grasp of these; and the latter to consist of a series of house appointments. The content of the course is to be based on requirements common to men who will become general practitioners, consultant-specialists, pathologists, research workers, and administrators; the special requirements of the several groups will be met by postgraduate rather than by undergraduate education. Therefore much that is now required in the undergraduate period can be omitted—for example, details of complicated diagnostic procedures, rare diseases, specialized treatment such as radiotherapy. The stress in the undergraduate period is to be on method, "for method is a more lasting acquisition than is fact, and without method a man is lost when he meets an unfamiliar situation, as he is ultimately bound to meet it away from his teacher's guidance." The second object should be the teaching of principle. The two should be used to show the student that the scientific method can be used in clinical study, and "that there is such a thing as clinical science."

### IMPORTANCE OF PATHOLOGY

The present method—or lack of method—of introducing the student into clinical work often bewilders him. The principles of pathology and bacteriology form a necessary introduction to clinical work. They should be illustrated by clinical material: for example, a study of inflammation would be illustrated by a case of conjunctivitis or cellulitis. "Seeing clinical material first in this light, the student would think of illness from the beginning in terms of disease processes." Another part of the introductory course should consist of lecture-demonstrations and practical exercises in the methods of history-taking and clinical examination. The student starting clinical work would begin with a three-month course in which the morning would be given to "lectures, demonstrations, and practical classes devoted to the principles of general pathology, the afternoons to lecture-demonstrations on clinical material designed to illustrate the course of pathology, and to introduce the student to some of the simpler disturbances of structure and function." After this he would begin the first ward appointment in general medicine or surgery, and in this teaching should be planned and not be governed by the fact that unrelated cases happen to be in adjacent beds.

Emphasis is laid once more on the problem of co-ordination, not only between the clinical and preclinical departments, but

also of the several divisions of clinical teaching. "The student's understanding of the essence of disease is increasingly handicapped by lack of co-ordination between the teachers who present the same disease-problems from the separate viewpoints of medicine and surgery; of such diseases peptic ulcer is a good example." Combined teaching, in which teachers of different specialties meet together to present their different views in front of the student, is looked on as one of the most valuable measures for overcoming incoordination in teaching. This benefits not only the student but also the teachers, who can then learn something of each other's points of view. The difficulty is that the clinical teacher at the moment has little time to spare. The department of pathology, it is observed, has "a unique opportunity for drawing together colleagues who . . . are tending to drift apart." Pathology should occupy a position of special importance in the undergraduate curriculum, and it is an essential part of the committee's proposal that the principles of pathology should form a major part of the introductory course of clinical work, the teaching to be confined mostly to principles.

### SPECIAL SUBJECTS

Special consideration is given to the place of psychological medicine, of social medicine, and of paediatrics in the curriculum. Of the first, it is observed, "We wish to awaken and to maintain the student's interest in matters of the mind from the beginning of his medical course"; of the second, "It should be the aim of all physicians and surgeons to permeate their teaching with an interest in social medicine"; and of the third, "The committee is agreed that paediatrics should be regarded as a major clinical subject on a par with obstetrics and gynaecology, and should occupy the whole time of the student for three months."

### Paying for Brains

After discussing ways of arranging for the compulsory year of residence, the committee considers the conditions of work and selection of clinical teachers. It recognizes that its proposals would make increased demands on teachers already heavily burdened. It recommends that clinical teachers should be paid for their teaching and hospital work. It deplores the falling off in the number and quality of young men specializing in pathology, "due probably to the more attractive remuneration and conditions of work offered by other careers."

As so much is implied by one paragraph under the heading of "The Place of the Teaching Hospital in an Organized Medical Service" we quote it in full:

"In the past, teaching hospitals have been institutions founded and financed for the treatment of the sick. Teaching and research have been, as it were, sidelines to which relatively small parts of the hospital's space, equipment, and budget have been devoted. It will already be apparent from the recommendations made, that the committee considers that the position of the teaching hospitals as centres of education and of research requires greater recognition and a much increased contribution from the public purse. For the campaign against disease is ultimately dependent on the progress of medical knowledge and on the efficiency of the medical profession, both of them deriving largely from the teaching hospitals."

It is difficult in this short space to pay full justice to what appears to us to be one of the most valuable reports issued by the Royal College of Physicians for some time. It reads as if it has been drafted by one pen, and to the wielder of this the profession at large is under a deep obligation.

During 1943 the Trustees of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation received eighteen applications for grants, thirteen of which came from the United States, the other five coming from five different countries in Europe, Asia, North and South America. In the twenty years of its existence the Foundation has made 481 grants, which have been distributed to scientists throughout the world. Researches are favoured that are directed towards the solution of problems in medicine and surgery, or in branches of science bearing on medicine and surgery. Information about the grants may be had from Dr. Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston, Massachusetts.

## Correspondence

### Cerebral Malaria

SIR.—We read with interest the article in the Dec. 25 issue by Dr. I. B. Sneddon called "A Fatal Case of Cerebral Malaria." Each year over 600 cases of malaria are treated in in-patients in this hospital. The scheme of treatment for the cerebral cases—reached by a method of trial and error over a number of years—is now the following:

On confirmation of diagnosis by highly positive M.P. film, clear C.S.F. and a low W.B.C., an intramuscular injection of quinine is immediately given. If the patient is very collapsed a small intravenous saline is sometimes given at this time, but never intravenous quinine. Four to six hours later a small intravenous injection of quinine is given: 3 to 6 gr. is ample. Adrenaline is given at all 5 given intramuscularly just prior to the intravenous quinine. Another small intravenous quinine injection can be given after a further four to six hours up to three such injections or the recovery of the patient. In December of this year we had six cerebral malaria patients. Only one died an infant of 13 years who had no intravenous injections.

We have found that large doses of intravenous quinine in cerebral cases in invariably followed by death. These cases all show a highly positive film. We have no copy of the 1942 edition of Manson-Bahr referred to by Dr. Sneddon, but in the 1940 edition, page 114, the following may be found: "The amount of toxin liberated by the rapid destruction of the parasites after intravenous injection [of quinine] may be sufficient completely to paralyse the cardiac mechanism, and death may rapidly ensue." In our minds there is no doubt of the truth of this. He goes on to advise intramuscular quinine followed by quinine intravenously.

What the "toxin" is, so far as we know, no one has ever found out. The common finding of jaundice in such cases suggests that it is rather the products of the burst-up red cells than something exuded by the parasites themselves. However, both of these factors may contribute to the "toxin," which seems to give rise to a form of protein shock—"autoprotein shock," if we may use the phrase.—We are, etc.,

### Kala-azar in an Adult contracted in Malta

SIR.—In the *Journal* of April 8 (p. 492) Wing Cmdr. Lipscomb and Squad. 1 dr. Gibson state: "We can trace only four recorded cases in adults whose infection cannot have occurred elsewhere than in Malta" in 1913-14, 1918, 1933, and 1934. In 1917, while in charge of the Medical Division of Valetta Military Hospital, Malta, I treated a case of kala-azar undoubtedly contracted in Malta, and heard of two others similarly contracted. As I left my notes in Malta and am quoting from memory I can only give the salient points, which were deeply impressed on my mind, and are as follows:

In the summer of 1917 a draft of No. 1 Malta Company, R.A.M.C., all British soldiers, paraded for inspection before proceeding to Salonika. At the conclusion of the parade it was remarked that Sergeant "G." was not only the smartest soldier on parade but the fittest. The draft was unavoidably delayed in the island owing to U boat activities, and some weeks later—possibly a month or six weeks—I was called to see this N.C.O., who was feeling ill, sweating, and had lost weight. On admission he looked ill, wasted, having lost 2 st. in weight, and from being a ruddy complexioned man had become sallow in appearance. On examination the only physical sign found was an enlarged spleen.

Colonel Sir Archibald Garrod, consulting physician to the Malta Command, who visited the hospital twice a week, saw him at his next visit and suggested to me that it might be a case of kala-azar. I pointed out that this N.C.O. had come straight from England two years previously and had never left the island since. Sir Archibald Garrod said that was no bar to contracting kala-azar, as he had already seen two soldiers who had contracted the disease in the island. The similarity of their symptoms and appearance plus the splenic enlargement suggested the tentative diagnosis of kala-azar. Acting on his advice splenic puncture was at once performed and Leishman-Donovan bodies demonstrated within a very short time of the patient coming under observation. He was treated by intra-

venous antimony injections; so far as I remember the solution was 1% tartar emetic. He always vomited before the needle was withdrawn from the vein, except on three occasions when he developed a severe irritation in one tonsil. He made an uninterrupted recovery, during the course of which he was visited by many people, including the late Lord Methuen, Governor, and Sir Thomas Yarr, D.M.S.

He corresponded with me for several years, and as an instance of the completeness of the cure told me that while on leave at his father's farm in England dived into a river and rescued a drowning sheep. Later in the war the ship he was in was torpedoed, and though he was in the water and boat for some time suffered no ill effects from the experience. I last heard from him several years ago when he was farming in Ladysmith and happily married.

It is interesting to record that shortly after this case I also treated a man of the Egyptian Labour Corps for bilharziasis in a similar manner with satisfactory result, the first time this treatment had been employed for this condition in Malta.

My own case of kala-azar was undoubtedly contracted in Malta, and Sir Archibald Garrod was not the type of man to make a statement like the above without a complete investigation. I believe I am right in saying that his opinion was that kala-azar was of more common occurrence in British adults in Malta than was generally realized. At any rate that is the impression left on my mind after twenty-seven years.—I am, etc.,

### Sickness Records of Hospital Nurses

SIR.—Dr. Joyce Wright's article (April 29, p. 585) on the sickness records of nurses in hospitals presented many interesting findings, but it would be instructive to compare the sickness records of hospital nurses who were respectively resident and non-resident in hospitals. Such a comparison might throw some light on the vexed question whether nurses should be accommodated in hospital or should be encouraged to live at home or in lodgings. In the hope that other hospitals may record their experiences where they have been similarly staffed, I have set out our experience in this hospital for the year 1943.

	No. of Nurses Employed	No. of Illness Absences	Days lost from Illness
Resident	124	97	1,534
Non-resident	154	163	3,300

The longest absence for a resident was 178 days; and the longest absence for a non-resident was 160 days. The hospital is situated in the country at a distance of 2 to 4 miles from centres of population where the non-resident nurses have their homes, lodgings, or billets. The non-resident nurses were under the care of doctors outside the hospital for the most part, though in a few cases treatment had to be given in the hospital.

The age groups of the two classes of nurses were not examined closely, but were known to be similar. The nature of the illnesses was also similar in the two groups to one another and to that given in Dr. Wright's article. The hours of duty for all non-residents amounted to 48 per week, whereas residents on the whole worked rather longer hours, usually about 52.

From these figures it would appear that residence has the advantage in respect of health; they are, of course, too small by themselves to establish a conclusion with certainty.—I am, etc.,

Clatterbridge General Hospital, Wirral.

D. WILKIE.

### Tuberculin Patch Test

SIR.—I should like to confirm Prof. Tytler's observations with regard to the efficacy of his tuberculin jelly. Some time ago he very kindly sent me a supply of this tuberculin jelly, which I used on a series of some 40 cases with (a) Mantoux test 1 in 1,000 controls, and (b) commercial patch test controls. I found that the results tallied exactly with those of the Mantoux test, and, so far as the commercial patch-test controls were concerned, the positive reactions with the jelly were stronger and much more reliable. In view of its practical importance it is to be hoped that Prof. Tytler's formula will soon be available for general use.—I am, etc.,

London, W.1.

PHILIP ELLMAN.

## SEROLOGICAL NOTES, NO. 1

**'WELLCOME'**  
BRAND  
**REFINED TETANUS**  
**ANTITOXIN**

**PROPHYLACTIC**  
**USE**

When tetanus antitoxin is used to confer passive immunity, it is imperative that the dose given should be sufficient to protect against heavy infection.

For many years, doses between 1000 and 3000 international units have been regarded as adequate for prophylaxis. Recent experience,\* however, indicates that 3000 units is the minimum prophylactic dose, and that this dose should be doubled or trebled when gross contamination has taken place.

In consequence, it has been decided to withdraw from sale the 1000 units packing of 'Wellcome' brand Refined Tetanus Antitoxin—Globulins. As a further safeguard against the administration of an inadequate prophylactic dose, the issue of Tetanus Antitoxin, 1000 units per c.c., in multiple dose containers will also be discontinued.

Existing stocks of these packings should be used in conformity with current recommendations, i.e., the contents of at least three 1000 unit ampoules, or an equivalent amount from a rubber-capped bottle, should be given as a prophylactic dose.

\* Monthly Bulletin of the Ministry of Health and the Emergency Public Health Laboratory Service, Vol. 2, October, 1943.

'Wellcome' brand serological products are prepared at The Wellcome Physiological Research Laboratories and are supplied by

## *The Successful Treatment of*

FIBROSITIS

and certain cases of

RHEUMATISM

with

NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in the great majority of cases, early and complete cure.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)." Please enclose 1d. stamp; all stamps received will be donated to the R.A.F. Benevolent Fund.

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: 1%, 1% and 2% Solutions.

Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

PHARMACEUTICAL MANUFACTURING CO., LTD., THE LABORATORIES, CHELTENHAM, GLOS.

### Cost of Living and the Nation's Health

SIR.—As doctors we are not as a rule concerned with the Budget proposals of the Chancellor of the Exchequer, except in so far as our own pockets may be affected and we may desire to express laymen's opinions on financial matters.

There is, however, one aspect of Sir John Anderson's Budget speech with which I venture to suggest, doctors, and particularly those interested in social medicine, are very directly concerned. The Chancellor stated (*Times* report, April 26) "that having regard to the higher domestic costs of production and also to import costs, he felt that for the ensuing year a range for the cost-of-living index of 30 to 35% over pre-war should be substituted for the 25 to 30% laid down by Sir Kingsley Wood in 1941." He also stated that "some part of the explanation [i.e., of increased subsidies] was to be found in the growing cost of imports, which affected particularly the food components of the index." If this is correct, it would appear clear that the main increase to be permitted in the cost of living will be accounted for by a rise in the price of foods. The chief foods to get subsidies are bread and flour, meat, potatoes, sugar, milk, cheese, and bacon, which form the foundation of our diet, and which last year received between them subsidies amounting to £149,700,000.

It has been estimated that a rise in the cost-of-living figure from the present index of 29% above pre-war level to the proposed 35% would represent an extra charge of £48,000,000, which would be thrown upon consumers, and at the present stage it would appear that the whole of this additional £48,000,000 will presumably be spent by the public on foods only. This is an average of over £1 per head per annum, counting every man, woman, child, and babe-in-arms.

Now it is generally agreed that the health of the country is remarkably good, and perhaps much better than many of us might have expected for the fifth year of the war. Not only has it remained good but new low records have been established in certain directions—e.g., maternal and infant mortality rates and standardized death rates among civilians, both male and female. In spite of supply difficulties it is doubtful whether very large sections of the population have ever been so well fed before as they are now, and it would be difficult not to ascribe some part of this remarkable wartime position as being due to the maintenance or improvement of the people's dietary in its essentials. In part it is no doubt due to the full employment with consequent higher family incomes, but full credit must also be given to the Ministry of Food and its scientific advisers for the job they have carried out of ensuring the more even distribution at reasonable prices of whatever foodstuffs have been made available, as well as for their schemes of extra supplies of special foods and food supplements for particular classes, either free or at greatly reduced prices—such as milk, cod-liver oil, and orange juice for mothers and children.

The maintenance or improvement of general nutritional standards is reflected in favourable health reports from all parts of the country, and from a medical point of view it would be deplorable that, at this stage of our knowledge, any steps should consciously be taken which may check and which may even in the long run eventually lead to a deterioration of the existing nutritional level. Sir John Boyd Orr and others have shown that the lower the income level the higher is the proportion of income which is spent on purchasing food. Any permitted increase in the cost-of-living index through a rise in the cost of essential foods will fall most heavily upon those who are least able to carry such an increase, and who will inevitably react by a reduction in either the quantity or quality of foods purchased, since the first-class proteins and protective foodstuffs are the most expensive.

Such is not the road to an improvement in the national health, but even on strictly utilitarian and economic grounds national efficiency in post-war rebuilding can only be assisted and not hindered by a people whose physical condition is at the maximum that can be attained through good nutrition. This point of view is also in full accordance with Principle A of the statement of Principles approved by the B.M.A., which says, "The health of the people depends primarily upon the social and environmental conditions under which they live and work. . . . upon nutritional standards. . . . The improvement

and extension of measures to satisfy these needs should precede or accompany any future organization of medical services."

I trust, therefore, that doctors will very carefully consider the possible health repercussions of this aspect of Budget policy.—I am, etc.,

Public Health Department, Islington.

V. FREEMAN.

## Obituary

### WILLIAM TURNER, M.S., F.R.C.S.

We regret to announce that Mr. William Turner, consulting surgeon to Westminster Hospital, died on April 30 in the hospital which he had served so long and so faithfully.

The son of Frederic Turner of Nizels, near Sevenoaks, he was born on Jan. 25, 1870, and from King's College School, London, went on to study medicine at King's College Hospital, where he was gold medallist of his year and won the Sambrooke Exhibition and first- and second-year scholarships. After qualifying in 1893 he served as house-surgeon and house-physician at King's. He graduated M.B., B.S. Lond. in 1895, winning a scholarship and gold medal, took the F.R.C.S. in the same year, and the M.S. degree in 1898. During the South African War he was surgeon to the Imperial Yeomanry base hospital, Deelfontein, and then medical officer in charge of the Imperial Yeomanry branch hospital, McKenzie's Farm. William Turner had been appointed assistant surgeon to the Westminster Hospital in August, 1897, and later served as senior surgeon for eleven years, retiring under the age limit in 1934, when he was elected consulting surgeon and a vice-president of the hospital. He was also consulting surgeon to the Dreadnought Hospital, Greenwich, the King Edward Memorial Hospital, Ealing, and the Royal Hospital for Diseases of the Chest, City Road. During the last war he was on the à la suite staff of the 4th London General Hospital with the rank of major, R.A.M.C.(T.), and also served on the visiting staffs of the King George Hospital, No. 22 American Red Cross Hospital, and Mrs. Michison's Hospital, Clock House, Chelsea. With his Westminster colleague, Mr. E. Rock Carling, he wrote *Treatment after Operation*, published in 1912. In 1936 he gave the Creasy Memorial Lecture, taking as his subject "The Acute Abdomen." He had been a member of the B.M.A. for 50 years.

#### Mr. ROCK CARLING writes:

I think I was Mr. Turner's first dresser in the out-patient department at Westminster; I have been his colleague for almost 40 years, and never ceased to learn from him. He had an unquenchable enthusiasm for his work and could genuinely feel that every patient might present something of unexampled interest; this lent a stimulus to his teaching that all his students felt. He was a very hard worker. With calls upon his professional services from several hospitals he could always find time for all the business committees of Westminster Hospital and Medical School, and his counsel was always sound. He was a colleague upon whose integrity and generosity one could count with complete confidence. He will be greatly missed.

Dr. ALBERT EDWARD BIRD, who died on April 1 at the age of 76, was a general practitioner in Burnley for 38 years until his retirement. He had been divisional surgeon and lecturer for the St. John Ambulance Association, and during the last war was commandant of the Auxiliary Military Hospital at Burnley. He joined the B.M.A. in 1905, served as honorary secretary of the Burnley Division as far back as 1911, and was later chairman; he had also been chairman of the Local Medical and Panel Committee and attended a number of Panel Conferences in London. He was very popular with his colleagues and greatly esteemed by all who knew him.

Dr. WILBERT GOODCHILD died at Threlkeld, Cumberland, on April 14 at the age of 67. As medical superintendent of Blencathra Sanatorium, Threlkeld was his home and centre of his activities for the past 39 years. He was the son of J. G. Goodchild of the Geological Survey of Scotland. Born in a scientific circle he decided on medicine as a career because the outlook

of any man wishing to devote himself to pure science was restricted. He graduated M.B., Ch.B. at Edinburgh University in 1903, and after a period as resident at Woodburn Sanatorium he was appointed medical superintendent of the projected Cumberland Sanatorium. He took charge of an embryo institution. The doctor's house was a reconstructed farmhouse and steading. From these small beginnings he directed its development to its present state of efficiency. In Edinburgh he came under the influence of Sir Robert Philip, whose methods of treatment became largely Dr. Goodchild's guide in developing his institution. He early realized the importance of occupational therapy, and with his patients and some outside assistance he designed and installed the electric supply for the sanatorium, as well as many other instructional and therapeutic agencies, as, for example, one of the earliest open-air cinematograph rooms. He thus kept himself and the sanatorium in the front rank of progress. Among his patients he was always sympathetic, and many will feel that they have lost their best friend. He was an expert geologist and mineralogist and contributed the mineralogical section to the *Technological and Scientific Dictionary*, equivalent to a condensed survey of the whole field of the crystallography and chemistry of minerals. His hobbies, if they can be so called, were not amusements but serious contributions to science. This applies to his work in the field of archaeology, more especially of the Stone and Bronze Ages. He was also a botanist and had at his home a very complete collection of British ferns and Alpine plants growing under natural conditions. He was visited by many people interested in the various branches of natural history, archaeology, and geology in which he was interested and recognized as an authority. They all received a hospitable welcome from Dr. and Mrs. Goodchild.

J. J. G.

We regret to record the sudden death recently at an early age of Dr. G. MACKERRACHER of Birmingham. George MacKerracher studied medicine at Glasgow, and took the M.B., Ch.B. of the University in 1922. After qualifying he was house-surgeon to the Victoria Infirmary at Glasgow and to the Guest Hospital and Eye Infirmary, Dudley. He subsequently went into general practice in Birmingham. The extra work imposed on MacKerracher as a result of the war threw a very heavy strain on him, which probably contributed to his sudden death. Quiet and unassuming, he represented all that was meant by "family doctor." He was held in high affection and regard by his patients and friends; the funeral service was largely attended by his poorer patients. In the last war he served in the Royal Navy. He leaves a widow and young son.

## Universities and Colleges

### UNIVERSITY OF OXFORD

In a Convocation held on April 27 the following medical degrees were conferred:

B.M. B.Ch. M.F.C. Walker and S. E. M. Bates (*in absentia*)

### UNIVERSITY OF CAMBRIDGE

At a Congregation held on April 28 the following medical degrees were conferred:

M.D.—F. T. G. Prunty, N. Whitaker, H. D. B. Kelly (*in person*); A. J. Daly, S. T. Anning, T. M. Banham, K. Robson (*by proxy*).

M.B., B.Chir.—P. L. Blaxter (*in person*); A. J. Briggs, J. H. M. Tilley, A. N. Exton-Smith, W. R. Probert, M. Ellis (*by proxy*).

### UNIVERSITY OF LONDON

Prof. D. Hughes Parry has been appointed a representative of the University on the Board of Management of the London School of Hygiene until Dec. 31, 1945, in place of Sir Girling Ball (resigned).

The Regulations in Medicine for Internal Students have been amended by the inclusion of the following paragraph:

"Students who enter a medical school in October (or January) but are unsuccessful at the first examination for medical degrees for external students in the following December (or July) will, subject to the approval of the authorities of their medical school, be admitted to the first examination for medical degrees as internal students in July (or December) provided they have attended the full course of study in all the subjects of the examination throughout the preceding three terms and have complied with the Regulations in other respects."

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following candidates have passed the Primary Fellowship Examination:

D. R. Barnes, I. Bruce, D. B. Feather, G. J. Fraenkel, R. A. Giff, G. Harrison, H. A. McDonald, A. Naylor, L. P. A. Newborne, C. B. Orchard, G. E. Stein

### ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a quarterly meeting of the Council held on April 29, with the President, Mr. Hardley Holland, in the chair, the Honorary Fellowship of the College was conferred on Sir Joseph Barcroft and Dr. E. Hastings Tweedy, in recognition of their services to obstetrics and gynaecology.

The following were admitted to the Fellowship:

J. H. Blakey, D. W. Currie, J. V. O'Sullivan, J. H. Peel. *In absentia*: H. L. McClure, A. W. Spira.

The following were admitted to the Membership:

John R. C. Boston-Brown, Agnes I. D. Cathcart, Audrey I. French, D. Friedlander, M. M. Garrey, Lilian D. M. Wilson. *In absentia*: A. P. Bernal, J. J. Kearney.

At the annual general meeting of the College, held on April 29, with the President in the chair, the following were elected to Council in place of those retiring by statutory rotation: *Representatives of the Fellows*: John Hewitt, J. E. Stacey, J. M. Wyatt. *Representatives of the Members*: J. H. Dewar, J. A. Stallworthy.

The meeting was followed by the William Blair-Bell Memorial Lecture, delivered by Mr. Hector R. MacLellan, M.D., F.R.F.P.S. Glas., M.R.C.O.G., entitled "Contracted Pelvis in Childbirth."

## Medical News

The Merseyside Group of the Association of Industrial Medical Officers will hold a meeting at Liverpool University, Surgical Theatre, at 4 p.m., on Tuesday, May 16, when Prof. Ryle of Oxford will speak on "Social Medicine, Experiments and Prospects." Members of the profession are invited.

A meeting of the London Association of the Medical Women's Federation will be held in the Common Room of B.M.A. House on Thursday, May 18, at 8 p.m., to discuss the White Paper.

Prof. Alexander Fleming, F.R.S., has accepted the invitation of the Council of the Royal Institute of Public Health and Hygiene to deliver the Hatten Lectures for 1944. His subject will be: "Penicillin—its Discovery, Development, and its Uses in the Field of Medicine and Surgery."

At a meeting of medical members of the British Institute of Radiology to be held on Friday next, May 19, in the Reid-Knox Hall, 32, Welbeck Street, London, W., Mr. H. S. Souttar will give the Mackenzie Davidson Memorial Lecture on "Team Work in the Treatment of Cancer" at 4.30 p.m. At the annual general meeting on Saturday, May 20, Prof. S. Russ will give the Silvanus Thompson Memorial Lecture at 3.15 p.m.

The Faculty of Radiologists announces that the Skinner Lecture on "The Natural History of Disorders of the Reticular Tissue" will be given by Dr. A. H. T. Robb-Smith on Saturday, May 20, at 11 a.m. in the Royal College of Surgeons, Lincoln's Inn Fields, W.C. The lecture is open to all members of the medical profession.

A special meeting of Fellows of the Royal Society of Medicine has been summoned for Tuesday, May 23, at 5 p.m., with the following agenda: (1) Nomination of officers and Council for 1944-5; (2) alteration of regulations regarding visitors' privileges in the Library; and (3) to approve enlargement of the Society's house and the architectural and financial preparations necessary therefor.

The annual general meeting of the Royal Medical Benevolent Fund will be held at the Royal Society of Medicine, 1, Wimpole Street, W., on Thursday, May 25, at 2.30 p.m., to receive and audit the annual report and balance sheet for the year 1943, and to elect the honorary officials, committee, and honorary auditors.

Dr. J. Pardon Martin will give a talk on ocular palsies at a meeting of the Clinical Society of the Royal Eye Hospital to be held on Friday, May 26, at 5.30 p.m., in the hospital (St. George's Circus, Southwark, S.E.).

The Minister of Health has appointed Dr. John Alexander Charles to be a Deputy Chief Medical Officer in the Ministry of Health. He will take up his duties on May 15. Dr. Charles has been M.O.H. for Newcastle-upon-Tyne since 1932, and is a member of the Minister of Health's Medical Advisory Committee.

The Empire Rheumatism Council announces that Lord Horder has received from Moscow for the Council a small supply of the anti-reticular serum of Prof. Alexander Bogolometz, which is stated to have specific influence upon rheumatic conditions. Tests on a scale limited by the amount of serum available are being made under carefully selected conditions, and results will be communicated to the medical press in due course.

The name of Dr. J. Cochrane Henderson has been picked by the King in Privy Council as High Sheriff of Westmorland. He is the first active medical man in the county to hold this honour.

The following appointments, awards, and mentions are announced in recognition of gallant and distinguished services in Sicily.  
O.B.E. (Military Division).—Lieut.-Col. F. B. Bowman and Major N. L. Elvine, R.C.A.M.C.  
Mentioned in Dispatches.—Col. C. H. Playfair, O.B.E., Major W. A. Oille, and Capt. W. H. Clare, R.C.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES  
Wounded.—War Subs. Capts. J. R. Dow, P. A. J. Smith, H. H. Watts, R.A.M.C.  
Prisoners of war.—Capts. P. T. Millard and R. E. Maffey, A.A.M.C.  
Killed in action.—Capt. E. Gibbon, R.A.M.C.

**DEATHS IN THE SERVICES**

**Capt. EDWARD ARCHIBALD WALKER, M.C., R.A.M.C.,** who died suddenly at Sheffield on April 9, was the youngest son of the late Major-Gen. James Grant Duff Walker and Mrs. Walker. He served in the war of 1914-18 in France and was awarded the Military Cross, being also mentioned in dispatches. Towards the end of the war he was wounded and taken prisoner of war by the Germans. He served for some years in the I.M.S., and on retirement from that Service he was in charge of the British hospital and colony at Oporto. On the outbreak of the present war he relinquished his practice in Portugal and rejoined the R.A.M.C. He was in charge of the reception station at Lincoln for two years and later was transferred to Sheffield. A colleague writes: He was high-minded and generous in judgment, courteous and philosophic, and these qualities, together with his cheerful disposition, made him a delightful companion. He was unassuming and quietly efficient; one with whom it was an honour and a privilege to work. For his kindness and sincerity he will always be remembered with deep affection and regard. He is survived by his wife and son, Lieut. Alexander D. Walker, R.E., at present serving in Burma.

Detention and Treatment of Mental Defectives  
Commons on April 25 Mr. BOWLES

Mr. WILLINK, in reply, said that there was much modern statute law on this subject. So far as admission was concerned, the safeguards were very substantial with regard to the medical certificate, the rights of parents, and in proceedings before the judicial authority, which consisted of selected magistrates. There were a great many checks on the certificate of any doctor. The question of the length of detention did not rest simply on the order made. Within seven days after admission, the medical officer of the institution had to make to the Board of Control his own medical statement on the case. He might concur or disagree with what the Court had done. If there was any disagreement there was consultation, and at any time, with regard to any case, the Board of Control could discharge the patient. The first order operated only for a year. So far as institutions were concerned, the Board of Control had directed that the detention should be extended to the quarter day after the original order, and, unless another order was made, the original order ceased to operate on that date. The subject was visited, and there were always two and more, often five or six visitors, including at least one medical man, who must be appointed under the Lunacy Acts, with special qualifications. It was far from being the case that there was any inducement to detain too long. At present many institutions were overburdened with serious cases, and applications could not be accepted

In a reply on April 27 to Mr. Sorensen, Mr. WILLINK said the scarcity of materials and labour for mentally defective children at present, but local authorities had been invited by circular to provide newly built accommodation for them in suitable houses to submit proposals for acquiring and adapting to meet their most pressing needs. The provision of accommodation to meet the post-war needs of these children was under consideration, but the extent of such provision must necessarily depend upon the conditions then existing.

On April 25 Dr. MORGAN asked the Minister of Health whether, in his negotiations up to the present with representatives of the profession, he had ascertained whether the medical profession were prepared to accept the Central Medical Board to be as outlined in the White Paper or whether their ideas ran in the direction of more unrepresentative corporate bodies such as the B.B.C., the Electricity Commissioners, the L.P.T.B., etc., or a corporate body of special constitution, practically granting workers' control to the medical workers of the proposed medical service. Mr WILLIAMS: No, sir, I have not yet received any official views from the profession's representatives on this subject.

On April 25 Mr. VIANI asked the Minister of Health whether the Service Departments were supplying Sir Arthur MacNalty, editor-in-chief of the official Medical History of the War, with full information of the diseases that had occurred and were occurring in all the theatres of war. Mr. WILLINK: I understand from Sir Arthur MacNalty that every effort is being made by the medical branches of the Service Departments to secure, for the official Medical History of the War, as full information as possible concerning the diseases that have occurred or are occurring in all theatres of operations in which British forces are taking part.

**Research: Income Tax Concessions**

In the course of his Budget speech in the House of Commons on April 25, Sir JOHN ANDERSON emphasized the importance of research. He said that an expenditure of a capital character, which meant normally expenditure on laboratory buildings, plant and machinery, should be allowed over a period of five years or over the life of the assets if shorter, as a deduction from profits for income tax purposes. In addition, all current research expenditure, such as salaries, wages, cost of materials, repairs, and so forth, would be allowed as and when incurred by the trader. This allowance of capital expenditure over a period of five years would be the rule for research for a trading concern in its own account. In addition, he proposed that any payment whether for a capital purpose or not, made by a trader to a central research body approved by the Department of Scientific and Industrial Research should be allowed as and when made as a deduction in computing the profits of the university or college on matters of concern carried out by the university or college or allowed. He hoped to the trader's business would similarly be allowed. Industrial research technique in the development of research. Industrial research workers must be provided not only with the physical apparatus which supplied their needs but with the motive that evoked their latent powers.

**Shortage of Beds for Tuberculosis**

In answer to Mr. Keeling Mr. WILLIAMS said on April 27 that he knew there was a shortage of beds in sanatoria for tuberculosis. Every effort continued to be made, so far as existing conditions allowed, to ease this problem by sanctioning emergency building within the present severe limitations of labour and materials; by recourse to whatever other supplementary accommodation could be made available, including beds in Emergency Hospitals; and by endeavouring to remedy shortages of staff required to bring additional beds into commission. During last year a net increase of some 1,500 beds was secured by these means.

**Penicillin**

Mr. LEWIS asked the Lord President of the Council whether any had been made by the Government for the purpose of providing penicillin for the treatment of tuberculosis.

On May 2 Major LYONS asked the Lord President of the Council what distribution of penicillin had been made by the appropriate committee of the Medical Research Council: on

what date or dates and to what aim were the quantities directed, respectively; was any particular test or condition excluded owing to shortage of supply; whether any and which of the recipient centres had published any report of its work in this connexion; and had it yet been considered by him. Mr. ARMITAGE circulated the following answer: "The Penicillin Clinical Trials Committee appointed by the Medical Research Council is responsible for the distribution only of a part of the penicillin supply which is allocated for research in this country; the remaining and larger part is going to the Forces overseas. The total quantity distributed by the committee up to the end of March, 1944, was about 500,000,000 units, of which about 420,000,000 units were divided between the hospitals in Oxford, London, and Edinburgh chosen as the main centres for clinical trial. The committee has also provided smaller supplies for specific clinical purposes to fourteen other centres in this country, and sixteen further projects for particular forms of study were approved at a recent meeting. The aim of these clinical trials is to treat cases under controlled conditions in order to determine the value of penicillin in different diseases and the best methods of its use. No proposals for any promising investigation have been rejected owing to shortage of supply. In some of the institutions work has not been in progress long enough to justify publication of results, but several reports have been issued and others are in prospect. A full account of the work at one of the main centres was published in the *British Medical Journal* on April 15. Such reports are of a technical nature, and were more for the consideration of the medical profession than of Ministers."

Mr. PIAT, replying to Mr. A. Edwards on May 2, said that the production of penicillin was being increased as rapidly as possible. He regretted, however, that it was not possible to give any reasonable estimate of the time when supplies would be available for general use in this country, as this must depend, among other things, on Service requirements.

#### Notes in Brief

Firms outside the Therapeutic Research Association are making penicillin. Sir Andrew Duncan says the general policy is to encourage production on the widest possible lines. Fears of monopoly are unfounded.

## EPIDEMIOLOGICAL NOTES

### Discussion of Table

In *England and Wales* during the week notifications of whooping-cough went up by 456, and those of measles by 206, but there were 263 fewer cases of scarlet fever, and 154 fewer of acute pneumonia.

There were only a few exceptions to the general decline in the incidence of scarlet fever, notably Lancashire, with 28 more cases than last week. In several counties there was a big increase in whooping-cough, especially in Essex, Warwickshire, Lancashire, London, and Middlesex, with rises of 81, 53, 50, 45, and 43 respectively over last week's totals. Lancashire reported 84 more cases of measles than last week, and Middlesex 43. The decline in acute pneumonia was greatest in the south; the south-eastern and south-western counties accounted for 94 of the 154 fewer cases.

A rise of 25 was recorded in the notifications of dysentery. The chief outbreaks were Northampton 37, Daventry R.D. 35; London 33, Woolwich 10; Southampton 21, Droxford R.D. 10, Petersfield R.D. 10; Lancashire 21; Middlesex 12; Derby, Heanor U.D. 12.

In *Scotland* the chief features of the returns were large rises in the notifications of measles, from 239 to 632 cases, and whooping-cough, from 56 to 178 cases. The rise in measles was due almost solely to the epidemic in Glasgow, where an increase of 333 was recorded over last week's figure. The biggest rises in incidence of whooping-cough were in the cities of Glasgow 56, Aberdeen 35, and Dundee 15. The notifications of dysentery fell by 19 but the incidence is still high. A fresh outbreak was recorded in Orkney County, involving 22 persons; the other large returns were Edinburgh 24, Glasgow 11.

In *Eire* the notifications of measles fell by 119, the highest returns for this disease being Dublin C.B. 73; Limerick C.B. 36; Dublin, Dun Laoghaire U.D. 35; Cork C.B. 31.

In *Northern Ireland* a general rise in infectious diseases was reported from Belfast C.B. Measles showed 12 more cases than last week, whooping-cough 11, and scarlet fever 8.

### Week Ending April 29

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1,764, whooping-cough 2,397, diphtheria 628, measles 2,055, acute pneumonia 711, cerebrospinal fever 71, dysentery 218, paratyphoid 4, typhoid 9.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) *England and Wales* (London included), (b) *London* (administrative county), (c) *Scotland*, (d) *Eire*, (e) *Northern Ireland*.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) *The 124 great towns in England and Wales* (including London), (b) *London* (administrative county), (c) *The 16 principal towns in Scotland*, (d) *The 13 principal towns in Eire*, (e) *The 10 principal towns in Northern Ireland*.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

### ANY QUESTIONS?

#### Localized Postural Oedema

**Q.**—May I have an expert opinion on the following clinical problem? The patient, usually a young woman, complains of oedema of the feet and ankles and occasionally the legs over a number of years. Sometimes this oedema is unilateral. Certain of these patients have work involving a great deal of standing, but as many have not. There is no familial history of the condition; no cardiac or renal abnormality; no varicose veins or phlebitis; no obvious pelvic lesion; no history of trauma; no flat feet or obvious vascular condition apart from some lividity of legs which does not resemble the type seen in erythrocytosis crurum puellarum frigida. Radiological investigation of the bones is negative. The swelling is worse at night and relieved by rest. It is not associated with pain. Could you suggest any other aetiological factors and lines of treatment?

**A.**—This is an excellent description of the condition known as idiopathic oedema, or, preferably, localized postural oedema. It is more frequent than is generally realized, as medical officers supervising women in industry and the Services have recently discovered. It often gives rise to needless alarm and is always troublesome to treat. In health, the filtration pressure of the blood in the capillaries is balanced by the osmotic pressure of the plasma proteins. The high venous pressure in the lower extremities, particularly in the erect position, entails a rise in the capillary pressure and therefore in the tendency to filtration of fluid into the tissues. Transudation of fluid into the legs on standing can be demonstrated in both males and females, and distinct oedema will occur if the foot is allowed to hang down motionless for some time. Normally, fluid does not accumulate, being expressed from the limbs by muscular movements and changes in position. It is a little difficult to see why the mechanism should break down and oedema develop in women, particularly young women. Diminished elasticity of the tissues is one factor, more particularly in association with tight shoes, high heels, and wrong posture. The water-retaining properties of the female sex hormones are probably also important, and it may be found that the oedema is worse about the time of menstruation. Local treatment is more effective than general, and consists in avoidance of high heels, massage and exercises of the ankles, contrast baths, and strapping with adhesive tape. It would be interesting to get statistics on the frequency of postural oedema in those who dance and those who don't, but reasoning *a priori*, the factory girls' passion for dancing should not be discouraged. Sometimes a formal manipulation of the ankle may be desirable. Tight garters, etc., should of course be avoided and overweight should be reduced. Of general measures, restriction of salt is probably the most rational. Calcium salts are indicated in theory but disappointing in practice. Small doses of thyroid and large doses of alkalis have also been used.

#### A Case of Bacterial Food-poisoning

**Q.**—A child, then aged 11 months, contracted a *Salmonella* poisoning, due to *B. aertrycke*, eleven weeks ago. Diarrhoea lasted six weeks, and there are still brief relapses, with loose motions, and the faeces are still infected. The usual treatment was given in the acute phase, and two courses of sulphaguanidine. What further treatment can be given to clear the infection?

**A.**—It is still a common assumption that an attack of bacterial food-poisoning produces such a violent reaction in the alimentary tract that everything, including the infecting organism, is quickly eliminated. The use of more selective culture media has shown, however, that after an attack of gastro-enteritis due to one of the *Salmonella* organisms the pathogen may persist in the gut for days or weeks after the patient is clinically well. As a rule these convalescent carriers clear up in 3 to 6 weeks, and only very rarely after infection with a *Salmonella* organism of the food-poisoning type does a chronic carrier-state supervene. In such cases aspiration

of duodenal contents should be done, as is advised in dealing with enteric carriers, to find if the pathogen is living in the gall-bladder. In children, infection with certain members of the *Salmonella* family is often accompanied by systemic invasion, giving rise to such conditions as continued fever and meningitis. It is also possible, as happens with the enteric group, that the organism may settle in the bone marrow.

In this particular instance the best advice is to "wait and see." The chances are that the carrier condition will clear up spontaneously, but if the organism continues to be excreted in the faeces in considerable numbers for 2 to 3 months more the likelihood is that there is a reservoir of infection either in the gall-bladder or in the bone marrow. If the gall-bladder is incriminated, cholecystectomy gives the best prospect of cure, although such a radical operation may not be thought advisable for the carrier of an organism which is not likely to cause serious illness in others. The intestinal sulphonamides by themselves are unlikely to effect a cure. Small daily doses of mag. sulph., such as used to be given for the treatment of bacillary dysentery, should be tried. American workers have claimed success from the use of the iodophthalmic dyes for the treatment of enteric carriers, but this claim has not been substantiated by British workers.

#### Cause and Treatment of Sprue

**Q.**—What is the current accepted view of the cause of sprue? Would it be possible briefly to state the general line of treatment, especially in the control of intestinal fluidness with the passage of sinking gases?

**A.**—The cause of sprue is unknown, but it is suggested that a dietetic deficiency, possibly some components of the vitamin B<sub>12</sub> complex but not of nicotinic acid only, brings about a metabolic breakdown leading to interference with the normal absorption, particularly of fats, from the alimentary tract. The basis of treatment consists in a high-protein, low-fat, low-carbohydrate diet, and the Ministry of Food has arranged for patients suffering from sprue to be allowed an extra meat ration in lieu of their butter. The total initial amount of diet depends on the severity of the disease and the tolerance of the patient, and is gradually increased as the patient improves. An average trial diet might consist of 3 to 5 oz. of underdone minced lean meat three times daily, with jelly, orange juice, a little glucose, rusks, and apple jelly; in the early stages of severe cases "sprulac" (a defatted dried milk powder) is useful. The absorptive failure in sprue may be associated with secondary nutritional defects. Commonly there is a macrocytic anaemia requiring the administration of liver extract—e.g., equivalent to half pound fresh liver daily—while vitamin C and nicotinic acid—e.g., 200 mg. daily—are important. Riboflavin may also be indicated where there is stomatitis, and hydrochloric acid in the presence of achlorhydria. Under proper dietetic treatment the symptoms usually subside rapidly and the patient steadily improves, but occasionally diarrhoea or meteorism may be troublesome for a time, in such cases castor oil followed by powdered chalk, charcoal, and kaolin may be useful. Any associated infection—e.g., *B. coli* urinary infection, which is not uncommon—should be treated on ordinary lines.

#### Indications for Circumcision

**Q.**—What is the modern teaching regarding the indications for circumcision? We feel that a great many unnecessary circumcisions are performed. Is it not sufficient in mild degrees of phimosis without obstruction to employ passive stretching instead? Is it justifiable to perform circumcisions where neither of these indications is present? We are under the impression that the prepuce subserves a useful purpose in protecting the glans penis.

**A.**—I agree that circumcision is often carried out unnecessarily. In the great majority of cases the prepuce can be separated from the glans penis with a blunt probe and withdrawn. Sometimes stretching is also required, and this can be done by means of vaselined artery forceps. Only when the prepuce is a very long one, or cannot be stretched, is circumcision necessary. Paediatricians say that many of these cases right themselves in time. But as circumcision in childhood has disadvantages unattached to circumcision in infancy, it is better not to rely on this. The prepuce undoubtedly has a function, but so far as can be seen circumcised men are not in any way penalized. They have the advantage of avoiding such troubles as recurrent attacks of balanitis and carcinoma of the penis.

#### Toxic Effects of Emetine

**Q.**—What are the possible toxic effects of emetine when used in the treatment of amebic dysentery? Textbooks warn us to watch for toxic manifestations, which are described as "cardiac" and "neutric"; but details are usually lacking.

**A.**—Tachycardia and cardiac irregularity sometimes occur after emetine has been given, but evidence of myocardial damage after therapeutic doses—e.g., 1 gr. daily intramuscularly or subcutaneously for not more than 10 days—is rare, and this is confirmed by electrocardiographic tracings. After intravenous injection, or large doses,

the tracings may show delayed conduction, diminution in voltage, and lowering or inversion of the T wave. It seems reasonable, therefore, to insist that patients receiving enetine should remain in bed during the whole course of treatment, and that the standard dosage recommended above should not be exceeded. Enetine in excess or prolonged dosage may cause diarrhoea, and the recurrence of diarrhoea towards the end of treatment for amoebic dysentery may be due to the drug; although this is rare, it sometimes leads the unwary to prolong the course excessively. Neuritis, myositis, desquamation, and atrophy of the nails have been recorded after enetine, but are uncommon. Apart from the fact that on therapeutic grounds closely repeated courses of the drug are rarely needed, it is undesirable, having regard to possible toxic effects, to repeat a course of enetine without allowing an interval of a week or two to elapse.

#### Solar Dermatitis

**Q.**—For many years I have had a patient who suffers from violent dermatitis due to the sun's rays. He is liable to boils and cracks of the face on any bright day. So acute is it that he cannot go out in bright weather and has to spend his time in a darkened room. I should be most grateful for any suggestion.

**A.**—A 10% freshly prepared watery solution of tannic acid is often successful. It should be applied to the exposed skin and allowed to dry on. When quinine is obtainable it may also be similarly used in a protective paste.

#### Ringworm of Nail

**Q.**—May I have advice on treatment of ringworm of the nail?

**A.**—Since drastic treatment is called for in this rare and rebellious form of ringworm, it is important to establish the diagnosis by microscopical examination or by culture. Complete surgical removal of the nail followed by dressing with 2% chrysarobin may succeed. Treatment with thionin X has proved successful in some cases.

#### The Oxford Vaporizer

**Q.**—(1) What precautions are necessary when using the Oxford vaporizer on a 6-weeks-old infant and in an old man of 80 years? What is the procedure to be adopted for the operation of tonsillectomy in children? (2) In what circumstances must the expiratory valve be screwed down? (3) Is it essential to deliver the ether mixture by compression of the bellows during the whole operation? (4) How much ether is to be put in for an operation lasting half an hour? and (5) is it safe to recover the remaining ether immediately after the operation? (6) Is it safer to use chloroform rather than ethyl chloride for induction?

**A.**—Many of the points raised in this query are dealt with in the booklet of instructions issued with the Oxford vaporizer. (1) No precautions are needed in an old man of 80, but in a 6-weeks-old infant, and for tonsillectomy, the bellows are used as *à vis* a *tergo* to drive over the ether air mixture to the patient. (2) The expiratory valve should be fully opened except in the rare cases in which the apparatus is used for artificial respiration. Here the expiratory valve is screwed down so that when the bellows are compressed nitrogen will be forced into the patient's lungs, and not escape out of the expiratory valve. (3) No, if the face-piece is firmly applied, compression of the bellows is unnecessary; when the patient breathes, concentrations of ether vapour reach the patient. (4) The amount of ether used depends very much on the type of patient and on the type of operation; roughly speaking 2 oz. will be used in an operation lasting half an hour. (5) It is quite safe to leave it in the vaporizer for many months. (6) The vaporizer can be used equally well after induction with either chloroform or ethyl chloride. The method of induction must be left to the man on the spot. An anaesthetic agent is made safe or dangerous by the man who uses it.

#### Marriage after Oophorectomy

**Q.**—Nine years ago a patient had her ovaries removed. She now wishes to marry (she will be aged 31 this year) and wants to know how this affects her physically, apart from not being able to have a child. How much ought she to tell her proposed husband, and will she be cheating him physically? She has been told by friends that in her state sexual intercourse is impossible. She is a highly intelligent young woman, virgin, and very sensitive. How would you suggest she should broach the subject to her fiancé, and how much do you think it best I should tell her?

**A.**—This is the sort of question which can really be answered much better by the family doctor than by the expert. One would like to know more about the reason for the removal of the ovaries at the very early age of 22, and much more about her psychology and that of her prospective husband. In general I think it is safe to say that she should tell him the whole truth. In the long run it would probably be better for the match to come unstuck now

rather than that she should be accused later of deception or, worse still, have to conceal so intimate a matter all her life. There is no reason to believe that she will be cheating him physically. If her vagina is normal he will be able to have intercourse with her normally. It is possible that she herself will not obtain the fullest possible pleasure, but even this does not necessarily follow, for some women continue to have orgasm after the menopause. She herself should be told the whole truth. As she is a very sensitive girl, you might well suggest to her that you should explain things to her fiancé, but whether you take this course must depend upon your estimate of her character and his. The question of substitution therapy might be considered, but only if she has menopausal symptoms. If there are present they will probably be well controlled by 1 mg. hexoestrol daily, or even less.

#### LETTERS, NOTES, ETC.

##### Tonsillectomy in Children

**Dr. L. DUTTON MATSON** (Birmingham) writes: I feel deeply indebted to Mr. Morton Marks for his letter on tonsillectomy in children (March 25, p. 436). After fifteen years in general practice I became increasingly sceptical about the advantages and benefits to health anticipated from this operation. But of the harm done to a child by neglect in having adenoidal vegetations removed, I have been acutely aware for some years now. At the present moment my youngest child is experiencing and illustrating some of these effects—continued "head colds," increasing mouth-breathing, culminating in almost complete deafness. The surgeon who will deal with him when the neuter catarrhal condition has subsided (and whom I met for only a few minutes; my family is evacuated, my wife ill—health results from "adenoids" rather than from unhealthy tonsils. I have a very genuine esteem, in collusion, for both of whose opinions the point. Mr. Morton Marks's letter and another I recall some months back to the same effect from a Shrewsbury surgeon (reference not to hand) have given me the moral support I need. The child will retain his hearing but retain his tonsils, and will suffer very much less pain and distress.

##### Pregnancy and Tuberculous Spine

**Dr. WILLIAM D. GRAY** (Bishop Auckland) writes: With reference to the "Any Questions?" of April 15 (p. 545) under the above heading, I have personal knowledge of three cases of the above. All were delivered of healthy babies, who are now growing up all right. Two of the mothers have suffered ill effects from the pregnancy. The first patient, now aged 32, conceived while lying in a plastic bed at home, and extension of the disease was found at the next x-ray examination. After delivery she developed a psoas abscess, which came and went, but has again recurred six years after delivery. The second patient, aged 26, who had a bone graft done when she was three or four months pregnant, was all right for several months, but then developed a cold abscess on the back in the region of the graft. This disappeared after aspiration. She kept well fit and loins, and x-ray examination showed partial absorption of the graft on the right side and a small paravertebral abscess. She is now awaiting further treatment. The third patient, aged 28, has gross kyphosis of the spine with extreme deformity, and had a sinus discharging for some years until 1941. X-ray examination at that time showed bony fusion. Her baby was born in 1943, but so far no evil effects have been noted.

##### Breathing Exercises

**Mr. HAROLD CHAPMAN** (London, W.1) writes: Reference to the use of breathing exercises after removal of tonsils and adenoids made in the *Journal* of April 29 (p. 609). Children frequently continue to keep their lips apart as a habit subsequent to the removal of tonsils and adenoids. If the relations of the upper and lower incisors are correct when the jaws are closed normally, the opening of the mouth can be cured by the simple exercise of holding a light object—e.g., an aluminium rod, 2 to 3 in. long, attached to tape while goes round the neck—with the lips. The more this exercise is done the quicker will a cure be effected. One should not hold the exerciser for an hour without releasing it; a skilled teacher is not essential for this; I give a few typed instructions. If the relations of the incisors are not normal, then it may not be reasonable to ask a child to keep the lips closed until the teeth have been corrected; when this has been done it is usually found that the bad habit has disappeared without treatment for the condition.

## THE COURSE OF THE DEATH RATE FROM PEPTIC ULCER IN GREAT BRITAIN, 1912-38

BY

Sir HENRY TIDY, D.M., F.R.C.P.  
Consulting Physician to St. Thomas's Hospital

This communication is a study of the trends of the crude death rates during the period 1912-38 for peptic ulcer and for gastric and duodenal ulcer separately, in males and females, for England and Wales, London (Administrative County), Rural Districts of England and Wales, and for Scotland. There are indications that striking changes have taken place during the last 20 years of the period. The data are from the Annual Reviews of the Registrar-Generals for England and Wales and for Scotland and the Annual Reports of the London County Council. With regard to age, the number of deaths has been taken separately for the age groups 20-39 years and for 40 years and over, and the death rates calculated per million living in the age group and sex group and area concerned in the various years. The death rates have also been calculated for the total of the age groups over 20 years.

Deaths from gastric ulcer were first recorded separately for England and Wales in 1901. For duodenal ulcer, deaths were first recorded separately for England and Wales in 1911, and for London, Rural Districts of England, and Scotland in 1921; deaths had previously been included in a mixed group of diseases of the stomach or intestines, but had not been classified with ulcer of the stomach.

The Registrar-General's Return of Deaths for England and Wales also gives statistics for Urban Districts and County Boroughs. Both may be regarded as mixed urban and rural populations scattered over the country. A test of a few death rates indicates that these do not greatly differ from each other or from the rates for England and Wales as a whole, and they will not be further referred to. London's is a purely urban population, and that of Rural Districts of England and Wales is the nearest approach available to a rural population.

The statistics for peptic ulcer for London and for the Rural Districts have been recorded on three different systems between 1912 and 1937. From 1912 to 1920 gastric ulcer alone is recorded. From 1921 to 1930 there are records for both gastric and duodenal ulcer. From 1931 the only return is for peptic ulcer. Thus there is no consecutive series from 1912 to 1937. For Scotland, as for England and Wales, there are records for both gastric and duodenal ulcer since 1921.

For England and Wales and the various areas full returns are not yet available for 1938. From 1915 to 1918 the return of deaths is for civilians only, nor is the age distribution of the population generally available. Consequently this period is omitted from consideration.

The number of deaths annually in certain groups is too small to permit of more than certain general deductions. In

the group of duodenal ulcer in females between 20 and 39 years the deaths do not exceed 10 in any one year for Scotland, London, and Rural Districts, and the death rate for England does not exceed 5 per million. There is no evidence of an increase in any area. The mean of the death rates for the period 1921-30 and for 1931-7 is 5 in each instance for Scotland and 3 for England.

Tables I-III record the crude death rates per million living for England and Wales, London (Administrative County), Rural Districts of England and Wales, and for Scotland, for

certain years between 1912 and 1938 which specially illustrate the course. They give the total rates for both types of ulcer together—i.e., for peptic ulcer—the rates for gastric and duodenal ulcer separately, for the two sexes, and for the age groups 20-39 years, 40 years and over, and the total over 20 years. Figures 1-4 are constructed from the annual returns, and show the trends during the periods.

FIG. 1.—Peptic ulcer. Population over 20 years of age. Crude death rates per million living.

FIG. 2.—Gastric ulcer and duodenal ulcer. Males over 40 years of age. Crude death rates per million living.

FIG. 3.—Gastric ulcer and duodenal ulcer in females. Crude death rates per million living.

FIG. 4.—Gastric ulcer and duodenal ulcer. Males between 20 and 39 years. Crude death rates per million living.

These returns solely relate to death rates. Care is necessary in drawing deductions as to changes of morbidity in the liver from the changes in the number of deaths and the death rate. For example, the case mortality of peptic ulcer under the age of 40 has fallen in hospitals during the last 20 years. Further, the experiences of the present war have proved that the incidence of such a serious complication as perforation may increase almost instantaneously under the influence of extremely severe stimuli, while the causes of a catastrophe such as perforation are not necessarily identical with the causes which lead to the formation of an ulcer. Nevertheless appreciable increases in the death rate of peptic ulcer over a series of years must correspond to an increase in the incidence of sickness in the community.

## I. ENGLAND AND WALES

For England and Wales the crude death rate from peptic ulcer for the population of the age of 20 years and over was 107 in 1912, 100 in 1921, 155 in 1931, and 159 in 1937 (Table I). The rate was almost the same in 1912 and 1921 and was practically stationary between 1931 and 1937, though at a higher level than in 1912 and 1921; but between 1921 and 1931 there was an increase of 50%. Thus this rapid rise was followed by a stationary period and preceded by a period in which no increase had taken place. When peptic ulcer is further analysed into groups, the increase is found to be almost entirely accounted for by males over 40 years. Further, it is found that the rise in this group, starting about 1921, ceased fairly rapidly about 1930-1, and was not resumed, but that the maximum rates in 1931 were subsequently maintained.

For males over 20 years the rates show a similar trend to the total for both sexes, being dominated by deaths of duodenal ulcer. For males between 20 and 39 the rates are approximately the same in 1912, 1921, and 1937—viz., 70, 7 and 74; there are no great variations in the intervening years but the rate rose to 93 in 1925 and 87 in 1928, and was about that level during this period, subsequently falling again.

For females the trends are quite different from those of males. For females of all ages over 20 years there was a sharp fall between 1912 and 1921, entirely due to decrease of gastric ulcer between 20 and 39 years. Rates are much lower than for males, and, apart from the group mentioned, changes have been small throughout the period.

It may be noted that no group of gastric or duodenal ulcer between 20 and 39 years in Britain showed a sustained increase in death rates from 1912 to 1938, except D.U. in males in Scotland—in contrast to the rises in groups over 40 years.

### Gastric and Duodenal Ulcer

The death rates and the trends between 1912 and 1937 show differences between G.U. and D.U. Differences in the trends will be considered later. The rate from G.U. is approximately double that from D.U. for males throughout, and at least four times for females. The excess of deaths from G.U. is greater than can be accounted for by the higher case mortality in G.U. as shown by the results from admissions to St. Thomas's Hospital, which over a long period give 12.5% for G.U. and 10% for D.U.

It may be noted here that an excess of deaths from G.U. over D.U. is true not only for the total deaths for England and Wales but throughout the period for both sexes, both age groups, and in all areas of Britain except for males after 1927 in Scotland. It may also be mentioned that deaths from G.U. in males over 20 years exceeded those from females in England and Wales for the first time in 1914; a similar change occurred in London in 1908, Scotland (finally) in 1916, and Rural Districts in 1920. For admissions to St. Thomas's Hospital the change occurred at some date between 1913 and 1921. The excess in males has subsequently remained

### Gastric Ulcer in Males

In 1912 the total number of deaths of males over 20 years was 857, and in 1921 it was 1,011, the death rate rising from 82 to 92 per million males living in this age group—an increase of about 12% in 9 years (see Table II). Between 1921 and 1928 the death rate rose from 92 to 150, a rise of over 60%. The rapid rise then ceased, the rate being 159 in 1931 and 167 in 1937.

**Death Rates Over Age of 40.**—The rate in 1912 was 127, in 1921 136, in 1928 236, and in 1931 260. The rate thus increased 74% in the 7 years 1921-8 and 90% between 1921 and 1931, being preceded by an almost stationary decade between 1912 and 1921 (see Table II and Fig. 2). The rise began suddenly in 1921, was at its maximum acceleration in 1925, slowed shortly after 1928, and practically ceased after 1931, the rate in 1937 being 273. Thus the rise was also followed by an almost stationary period of years, with no fall after cessation of the rise.

**Death Rates in Age Group 20-39.**—The rate in 1912 was 43, in 1921 44, in 1931 49, and in 1937 46. There was a small transient rise to 59 in 1925, and the rate was 55 in 1928. This rise corresponded to the most rapid rise in death rates over 40 years, and was mainly due to the later ages in the group. The rise subsided, and the rate was approximately the same in 1912 and 1937. The trend is in contrast to that of the age group over 40 years. The ratio of the death rate over 40 years to that of the age group 20-39 was 3 to 1 in 1912 and 6 to 1 in 1937.

### Duodenal Ulcer in Males

**Death Rates Over Age of 40.**—The rate in 1912 was 70, in 1921 74, in 1928 128, and in 1931 147. The rate thus increased 73% in the 7 years 1921-8 and 100% between 1921 and 1931, being preceded by a stationary decade between 1912 and 1921. The rise began in 1921, was at its maximum acceleration in 1925, and reached its maximum death rate of 147 in 1931. Subsequently between 1931 and 1937 there was no indication of a further rise or of a consistent rise or fall; the range was between 130 and 150. The trend of the curve resembles that for G.U. The rise proportionately is almost identical, the ratio of G.U. to D.U. being constant during the period at 1.8 to 1.

**Death Rates in Age Group 20-39.**—The rate may be regarded as stationary between 1912 and 1937. The rate was 27 in 1912 and 28 in 1937, the range of the rates being from 26 to 34.

### Gastric Ulcer in Females

This group has certain special features. The total number of deaths of those over 20 years of age in 1912 was 897 and in 1921 705, the death rates being 77 and 55. The death rate in 1937 was 54, the range between 1921 and 1937 being 54 to 59. The number of deaths in 1912 has not been exceeded subsequently (except in 1914), in strong contrast to the course in males. The incidence in the age groups over 40 and between 20 and 39 years is so different that the total rate over 20 years is no guide to the trends.

**Death Rates Over Age of 40.**—The death rates in 1912 and 1921 were 94 and 82 respectively. (1921 was an exceptionally low year.) A moderate rise and fall had taken place between 1912 and 1921. After 1921 there was a slight rise of doubtful significance to 95 in 1925, and subsequently the rate remained stationary until 1937, the range being between 88 and 96. Thus the changes in rates between 1912 and 1937 were small, and between 1925 and 1937 were negligible.

**Death Rates in Age Group 20-39.**—The course of this group is very interesting (Fig. 3). Jennings (1940) has paid special attention to it. In 1912 deaths numbered 386 (death rate 63), being about 43% of the total of 897 over 20 years. In 1921 deaths were 175 and in 1937 were 54, the rates being 28 and 8. Between 1912 and 1937 the fall is continuous and uninterrupted, and shows no relation to the course of any other group. The death rate had been falling rapidly previous to 1912.

**Deaths under 20 Years.**—These form a striking illustration of the fall in incidence in young women. In 1912 they numbered 76, in 1921 24, and in 1937 only 1. Deaths under 20 years are now practically liquidated—at least temporarily—and under 40 years are nearly so.

### Duodenal Ulcer in Females

The death rate from D.U. in females is low at low ages. The total deaths over 20 years in 1912 were 111, in 1921 110, and in 1937 207, the death rates being 10, 9, and 15, while in males the rates were 47, 51, and 93 respectively.

**Death Rates Over Age of 40.**—The rate in 1912 was 16, in 1921 13, and in 1937 24. Between 1921 and 1925 there was a moderate rise, probably significant, from 13 to 24. This corresponds with the period of maximum rise in the male group. The higher rate was maintained after 1925, but there was no further rise. The range of the death rates between 1925 and 1937 was from 19 to 24.

**Death Rates in Age Group 20-39.**—It has already been mentioned that the rate did not exceed 5 in any year between 1912 and 1937, and there is no indication of an increase.

### Ratio of Death Rates

**Males to Females.**—For peptic ulcer at ages over 20 years the ratios in 1912, 1921, 1928, and 1937 were 1.5, 2.2, 3.3, and 3.8 to 1 respectively. The preponderance of males is rising rapidly.

**Gastric to Duodenal Ulcers.**—In the years as above the ratios of G.U. to D.U. were 3.0, 2.6, 2.2, and 2.1 to 1 respectively. The fall in the ratio in the earlier years was due to the rapid decrease of G.U. in young women. Since 1925 the ratio has been constant approximately at 2.2 to 1. For males over 40 years the ratio has been constant throughout at 1.8 to 1, and from 20 to 39 years between 1.7 and 1.8 to 1.

### Remarks

In 1912 the death rates of the various groups were fairly close together, but they are now splayed out by the great increase which has taken place in certain groups since 1921 while others have remained stationary. The trend of the rates for peptic ulcer, for G.U., and for D.U. is now mainly dictated by the rates for males over 40 years.

The difference between the rates in 1912 and 1921 in all groups is small. **Male groups over 40 years.** both G.U. and D.U., suddenly began to rise in 1920-1, and for several years the rise was very rapid: it was most rapid between 1921 and 1925. After 1928 it definitely slowed down, and the rise practically ceased in 1930. The increase between 1921 and 1931 was 90% for G.U. and 100% for D.U. D.U. apparently entirely ceased to rise after 1930, but G.U. in this group may have continued to rise slowly until 1937. But, although the rise ceased, no fall followed: the maximum rate was maintained.

Rates for females have shown little tendency throughout the period either to rise or to fall, except for G.U. under 40 years. There was possibly a slight significant rise in D.U. over 40 years between 1921 and 1925 and an even smaller rise for G.U., but rates show little difference between 1912 and 1937. Gastric ulcer in females under 40 years clearly pursued a course of its own with an uninterrupted fall which had started some years before 1912. Other groups under 40 years show only slight variations throughout the period, and there is little difference in the rates for 1912 and 1937. Both

G.U. and D.U. in males had slight temporary increases between 1921 and 1925 during the sharpest rise in the later age group, and mainly due to ages near 40.

### Summary

Death rates from G.U. and D.U. and in the various age and sex groups were almost the same in 1912 and 1921 (except for G.U. in females under 40 years).

In the period 1921-30 there were rapid increases in the rates for both G.U. and D.U. for males over 40. The maximum increase was between 1921 and 1925: the rise further slowed about 1928, and ceased in 1930. The rise was about 90% for G.U. and 100% for D.U.

Between 1931 and 1937 there were no further sustained changes in these groups. The maximum rates reached in 1931 were substantially maintained.

For the group G.U. in females 20-39 years the rate fell uninterruptedly from 1912 to 1937. Deaths under 20 years fell almost to zero.

In other female groups there was little change between 1912 and 1937.

Groups under 40 years, both male and female (except G.U.), showed little change between 1912 and 1937. Some groups had temporary rises between 1921 and 1925.

The ratio of the rates for males to females is rising rapidly, especially over 40 years.

The ratio of the rates for G.U. to D.U. since 1921 has been 1.8 to 1 for males and at least 4 to 1 for females.

## II. LONDON (ADMINISTRATIVE COUNTY)

The total number of deaths from peptic ulcer in London in recent years has been between 500 and 650 annually, of which nearly half are in the group of gastric ulcer in males over 40 years. The numbers are small in certain groups, and vary considerably from year to year.

### Gastric Ulcer in Males

In 1912 the rate from G.U. in males over 20 years was 120, and thus was considerably higher than the rate for England, which was 82. In 1921 the rate was 119, no rise having taken place. From that year the rise was rapid—mainly due to the group over 40 years.

*Over 40.*—There are indications that the rate was rising between 1912 and 1914, but in 1921 it was slightly lower than in 1912. From 1921 the rate rose rapidly. The trend resembles that of England, but the rates are definitely higher and the increase is greater. The rise was most rapid between 1921 and 1925, the increase, from 172 to 287, being 66%. The rate of rise was slowing after 1928, but the death rate was still increasing in 1930, when the records cease. The rate then was 390—about 50% higher than that for England. The total rise between 1921 and 1930 was 120%, the rise for England being 90%. As the rate for peptic ulcer, in males over 40, combining G.U. and D.U., rose only slightly after 1930, the rate for G.U. alone could not have greatly increased, but it may have done so in a moderate degree.

*Aged 20-39.*—The numbers are small. The trend closely resembles that for England, and there is a similar slight rise between 1921 and 1925. Owing to the small numbers the rates are irregular, but they are higher than those for England.

### Duodenal Ulcer in Males

Duodenal ulcer was first recorded in 1921, the rates for males over 20 years being 58—half the rate for G.U. and slightly higher than the rate for England.

*Over 40.*—The rate rose rapidly from the first return in 1921, when it was 85, England being 70. The trend closely resembles that of England. The rise was slowing after 1925. There is no rise between 1928 and 1930—suggesting a cessation similar to that of England after 1930. The rise had then been 100%. The rates are about 20 to 25% higher than those for England, but the difference is not so great as for G.U., nor was the difference increasing so markedly between 1921 and 1930.

*Aged 20-39.*—The numbers are small, the range of deaths annually being between 16 and 30. No definite deductions can be made, but there are no indications of a marked rise or fall.

### Gastric Ulcer in Females

The rate in 1921 for females 20 years and over was somewhat lower than in 1912, and both rates closely agree with those for England.

*Over 40.*—The rate rose steadily from 1921 to 1930, increasing from 98 to 141, and thus differs from that for England, which was stationary. As peptic ulcer in females, of which this group supplied 75% of deaths, had no sustained rise after 1928, the group could not subsequently have appreciably increased.

*Aged 20-39.*—The rates fell steadily from 1912 onwards, and were not higher, and indeed were slightly lower, than those for England. (The rate for 1930 was exceptionally high.)

### Duodenal Ulcer in Females

The numbers are very small, the deaths ranging from 11 to 26. Between 20 and 39 years deaths are negligible, only one being recorded in 1928. Over 40 years, there may be a slight increase. The trends and rates do not appreciably differ from those for England.

### Peptic Ulcer

The rates for peptic ulcer can be followed from 1921 to 1937. The rate for males of 20 years and over in 1921 was 177—25% higher than for England, which was 143. There was a very rapid rise between 1921 and 1925, and it continued to be rapid until 1928-30, when the rate was 354, England being 250—a difference of 40%. There was no further increase after 1930. The range from 1930 to 1937 was between 326 and 354.

*Males Over 40.*—The trend of the rates closely resembles that for all ages over 20 years. The rates in 1934-7 were about 600, and for England rather over 400, London being nearly 50% higher. In 1921 the rates were 257 and 210 respectively.

*Males Aged 20-39.*—The rates were the same in 1921 and 1937, no sustained rise having occurred, although there was an unusually high rate in 1930. The rates are about 15% higher than for England.

*Females Over 40.*—There was a moderate rise from 1921 to 1925, due to G.U. After 1928 there was no further increase. The rate in 1937 was 150, against 113 for England, the rates for London being about 25% higher than those for England.

*Females Aged 20-39.*—The number of deaths is very small in this period and the death rates are low. The rates and trend closely agree with those for England.

*Ratio of Death Rates of Males to Females.*—For peptic ulcer in those over 20 years the ratios in 1921, 1928, and 1937 were 2.7, 3.5, and 4 to 1 respectively, and are somewhat higher than those for England.

*Ratio of G.U. to D.U.*—The ratio was 2.8 to 1 in 1921 and 2.4 to 1 in 1928. For males over 40 the ratio in 1921, 1925, and 1928 was 2.0 to 1. The numbers under 40 years are too small to give the ratio.

### Remarks

London has a higher death rate from peptic ulcer than England, and has had a greater rise since 1921. The excess is shown by all groups over 40 years, but is greater for G.U. than D.U., for both males and females, so far as the records are available. Groups aged 20-39 show no great differences from those for England, but G.U. in males is somewhat higher. In general trend the rates over 40 years resemble those for England. There is a similar absence of rise between 1912 and 1921 (for gastric ulcer), a rise at its maximum between 1921 and 1925, and a cessation of further rise after 1930 with maintenance of the highest rates.

### Summary

The crude death rates for peptic ulcer, both males and females, between 1921 and 1937 for London were higher than for England, and rose more rapidly between 1921 and 1930.

The rate for G.U. in males was the same in 1912 and 1921.

Between 1921 and 1930 there were rises in all groups over 40 years except D.U. in females. The rate for G.U. in males rose 120%, and in 1930 was 50% higher than for England. D.U. in males rose 100%, and in 1930 was about 25% higher than for England. G.U. in females rose 40%, and in 1930 was that proportion higher than that for England, which had remained stationary.

Rises were greatest between 1921 and 1925, and slowed between 1928 and 1930. Subsequently there was no substantial rise, but the rate for males over 40 years may have increased to a small degree.

For groups aged 20-39 the rates and trends do not differ greatly from those for England. G.U. in males rose slightly and in females fell consistently. D.U. showed little change. Numbers are small.

London resembles England in the general trend of the rates, except for G.U. in females over 40 years. London differs from England quantitatively in that the rates over 40 years are appreciably higher than for England, the excess being greater for G.U. than for D.U., and greater for males than for females. The differences increased between 1921 and 1930. The ratio of males to females is higher for London.

### III. RURAL DISTRICTS OF ENGLAND AND WALES

The trend of the death rates for Rural Districts in general resembles those for England and for London. Thus the rate for G.U. in males is the same in 1912 and 1921. Between 1921 and 1930 there are rises, in male groups over 40 years, which are most rapid between 1921 and 1925. After 1930 the groups show no consistent rise or fall, except that the rate for males over 40 years may be slowly increasing, probably due to G.U., which was still rising slowly in 1930, while D.U. apparently had become stationary. The group of G.U. in females aged 20-39 falls. Other groups for females, and other groups in ages 20-39 years for both sexes, show little change between 1912 and 1937, with some moderate exceptions similar to those occurring for England. While such trends are similar, there are certain considerable quantitative differences between Rural Districts and England and London, especially the last-named.

#### Gastric and Duodenal Ulcer in Males Over 40 Years

For gastric ulcer the rate in 1921 was 109 and in 1930 201, a rise of 85%, compared with 90% for England and 120% for London. The rate of 201 in 1930 compares with 260 for England and 390 for London, and is thus 25% below that for England and little more than half that for London.

For duodenal ulcer the position is not dissimilar, but differences in rates are smaller. The rise between 1921 and 1930 was nearly 70%, compared with 100% for England and London. The rate of 107 in 1930 compares with 150 for England and 168 for London.

**Aged 20-39.**—Numbers are small, but the rates are consistently below those for England and London. There are slight rises in rates between 1921 and 1925, as for England, but otherwise no material change.

#### Gastric Ulcer in Females

**Over 40 Years.**—The rate is unchanged between 1912 and 1930, resembling the trend for England, so far as records are available, but at a slightly lower rate. There is no indication of the rise which occurred in London between 1921 and 1930.

**Aged 20-39.**—The rates fell regularly, but this group differs from all others in that the rates for Rural Districts, though low, are higher than for England and for London. In 1912 the respective rates were 75 for Rural Districts, 63 for England, and 47 for London. The average for the years 1921-8 is 25, 21, and 16 respectively. Although the differences are not great, they are constantly present, and it is also noticeable that the rates for London are somewhat lower than those for England.

#### Peptic Ulcer

The rates for peptic ulcer are available up to 1937. They are consistent with the trend of the rates for G.U. and D.U. separately in 1930—viz., that G.U. in males over 40 years might be slowly rising and other groups were stationary. The rates for females at 20-39 years, which must be nearly all G.U., are still higher than for England and London, the average for 1931-7 being 22 for Rural Districts, 14 for England, and 15 for London.

**Ratio of Death Rates of Males to Females.**—For peptic ulcer over 20 years the ratios in 1921, 1928, and 1937 were 1.6, 2.3, and 3.3 to 1 respectively, and are lower than for England.

**Ratio of G.U. to D.U.**—The ratio was 2.5 to 1 in 1921 and 2.3 to 1 in 1928. For males over 40 years the ratios in 1921, 1925, and 1928 were between 1.7 and 1.8 to 1. The constancy of this ratio for males over 40 years may be noted. It was unchanged for England from 1921 to 1937 at 1.8 to 1, and also at 20-39 years almost at the same ratio. It was constant for London from 1921-8 at 2 to 1.

#### Summary

The death rates from peptic ulcer, especially for males, in Rural Districts are lower than for England and greatly lower than for London.

The trends of the rates do not greatly differ from those for England.

**For males over 40 years** the rate for G.U. in 1930 was 25% less than that for England and about half that for London. The rate for peptic ulcer was closely similar, and remained so up to 1937.

The rates in groups for females in general are slightly lower than for England.

The rates in groups 20-39 years also are slightly lower than for England.

**G.U. in females of 20-39** is an exception, as the rates, though low and falling, are consistently higher than those for either England or London from 1912 to 1937.

The ratio of males to females is lower than for England and considerably lower than for London.

The ratio of G.U. to D.U., where available, was constant at 1.7 or 1.8 to 1 and the same as for England.

### IV. SCOTLAND

The trend of the death rates in Scotland affords additional evidence of the rapid changes in the incidence of peptic ulcer which have taken place since 1921, but there are certain differences from the areas so far discussed.

The death rate from G.U. over 20 years of age for both sexes in 1912 was 106, and was thus considerably higher than that of England, which was 80, London being 95. Between 1912 and 1921 there was little change. In 1921 the ratio of deaths from G.U. to D.U. was 3 to 1, England's being 2.5 to 1.

The death rates from peptic ulcer over the age of 20, available from 1921 onwards, are higher throughout than for England. The rates in 1921 and 1937 were 134 and 209, and in England 100 and 159. In 1921 the rate in each age group and sex group of G.U. and D.U. was higher than in the corresponding group for England. It was also higher than in the corresponding group for London, except for D.U. in males, in which the rates were the same. Subsequently the trends for males widely differ.

**Gastric Ulcer in Males over 40.**—In 1912 the death rate was 178. In 1921 it had risen to 215. (In this year D.U. was introduced into the statistics.) From 1921 the rate fell slowly to about 200 in 1931. In 1934 the rate began to rise again, and was rising sharply in 1937, when it was 259, and in 1938, when it was 267. The course is in marked contrast to England (and London), in which there was a rise of 90% between 1921 and 1931, and subsequently only a slight rise between 1931 and 1937.

**Duodenal Ulcer in Males over 40.**—The rate rose rapidly from the first return in 1921, which was 88—somewhat higher than the rate for England and the same as for London. Between 1921 and 1931 the rate was almost tripled, rising from 88 to 259. There was a constant increase in the rate between 1921 and 1928. Subsequently between 1931 and 1938 there was no further sustained rise, the rate in 1938 being 262. The range in this period was between 241 and 300.

This course is in marked contrast to G.U. in males over 40, and the D.U. curve crosses the G.U. curve in 1928. After diverging widely the rates were equal again in 1938. Compared with England, the rise between 1921 and 1931 is more than double, but in both there was no sustained rise after 1931. The rates rise above those for London after 1925.

**G.U. in Males Aged 20-39.**—The rates show only small changes between 1912 and 1938, and the trend resembles that for England.

**D.U. in Males Aged 20-39.**—The rate in 1921 was 30—somewhat higher than for England and London. From 1921 the rates rose proportionately rapidly until 1928, when the maximum of 82 was reached. Subsequently most of the rise was maintained. This is the only group of 20-39 years in which a sustained rise has occurred since 1912. The numbers are small and the increase is mainly accounted for by ages near 40 years, but the rise between 1926 and 1928 is apparently significant.

**G.U. in Females Over 40.**—The course shows some transient rises, but tended to fall slowly between 1912 and 1938. The rates are considerably higher than for England, but about 1926 were exceeded by those for London, which were then rising.

**Gastric Ulcer in Females Aged 20-39.**—The rates fall continuously, as in areas already discussed.

*Duodenal Ulcer in Females.*—Over 40 years the numbers are small. There may have been a slight rise. For ages 20 to 39 the numbers are negligible.

*Peptic Ulcer Over 20.*—The rates are higher than those for England. They were closely similar to London's in 1921 and 1937, but the trends were different during the period. The rates rose rapidly until about 1928, then more slowly until 1934, and then again rapidly. The curve is clearly composite.

*Ratio of Death Rates of Males to Females.*—For peptic ulcer at ages over 20 years the ratios in 1921, 1928, and 1938 were 2.1, 2.5, and 3.7 to 1 respectively.

*Ratio of Death Rates of Gastric to Duodenal Ulcer.*—The ratios for males over 40 years in 1921, 1928, 1931, and 1938 were 2.5, 1, 0.75 and 1 to 1 respectively.

### Remarks

The death rates from peptic ulcer are higher than for England throughout the periods for which returns are available. The rates are slightly lower than for London, but appreciably higher than for Rural Districts of England. The excess was shared in 1921 by G.U. and D.U., but later was due entirely to D.U., G.U. having fallen behind England. There was a rapid rise between 1921 and 1938, as in England, but with considerable differences in the contributory groups. For G.U. in males over 40 the contrast between the courses in England and Scotland is striking. For D.U. in males over 40 both countries show a rapid rise between 1921 and 1931 and subsequently a stationary period until 1938, but the rise in Scotland was double that in England. The death rate for this group in 1921 was only 88, and it is unlikely that it had been rising rapidly previously. The trend for G.U. in females under 40 resembles that for England.

### Summary

Death rates from peptic ulcer over 20 years increased rapidly between 1921 and 1928, more slowly to 1934, and rapidly again to 1938. The rates are higher than for England and appreciably higher than for Rural Districts, and usually slightly below that for London. The trend differs from that for England.

G.U. in males over 40 rose between 1916 and 1921. There was no further rise until 1934, when the rate rose rapidly until 1938. The trend is in marked contrast to those of England, London, and Rural Districts. The rates for G.U. in males under 40 have shown no material change, and resemble those for England.

D.U. in males in 1921 had approximately the same rate as in England and London. The rate rose very rapidly from the first records. For the group over 40 it had nearly tripled by 1931, the rise being greatly in excess of that for England; it then became practically stationary until 1938, as in England. The curve crossed that for G.U. in 1928, but after diverging widely the two rates were practically equal again in 1938.

D.U. in males under 40 rose between 1921 and 1928. The rates are higher than in England and London. The numbers are small.

G.U. in females over 40 shows no sustained rise between 1912 and 1938. The group under 40 has fallen continuously.

D.U. in females gives no indications of a material increase.

All rises which took place over a course of years were subsequently maintained, no material fall taking place.

### V. GENERAL REMARKS

No attempt is made here to consider fully the causes of the trends of the death rates, but attention may be directed to certain points, further study of which might assist in elucidating the predisposing causes of peptic ulcer.

*Trends in Males over 40.*—The curves for England, London, and Rural Districts possess the same general characteristics. Between 1914 and 1921 there is no material rise. From 1921 to 1925 there is a rapid rise, which slows from 1925 or 1928 to 1930. Subsequently the rate is practically stationary. G.U. may be rising slowly, but there is a change about 1930 similar to that for D.U., but not so complete. The contrast between 1921–30 and 1931–7 is definite. The maximum rates reached about 1930 are substantially maintained. These trends could be explained by new factors, introduced in 1921, reaching their maximum effect about 1930. The possibility that the rises are due to improved diagnosis and recognition is negated by the

rates for women and for ages under 40, which show no similar increases and are mostly unchanged throughout the period.

The rate for D.U. in Scotland in 1921 was close to that for England and for London. Between 1921 and 1930 the rise was twice as great as for England. Subsequently the rate became stationary, as in England. The differences are quantitative.

For G.U. in Scotland, the difference from England is not merely quantitative, as there is a complete absence of rise between 1921 and 1934. The possibility of mass differences in diagnosis is negated by the curve for peptic ulcer, combining G.U. and D.U. This is quite different from that for England and English areas, and is clearly a composite curve.

*Gastric Ulcer in Females Aged 20–39.*—The rates fall continuously, the trends being the same for England, English areas, and Scotland. The rates are highest in Rural Districts. These trends point to the existence of and disappearance of external factors, acting as predisposing causes of the manifestation of a certain group of peptic ulcer. This does not exclude the possibility of psychological stimuli acting as exciting factors.

*Peptic Ulcer in Other Groups of Ages 20–39.*—There is little change in all other groups of these ages. Death rates will be affected by the reduction in case mortality which has taken place at these ages since 1921, but it would be curious if this so exactly balanced any great rise in morbidity.

*Peptic Ulcer in Females.*—There has been no significant rise, except for G.U. over 40 years in London over a limited period.

### General Summary

*Calendar Periods.*—(a) Between 1912 and 1920 there was little or no rise in rates for peptic ulcer, or for the various groups when returns are available; (b) between 1921 and 1930 there was a rapid rise in many groups; (c) between 1930 and 1938 there was little or no further rise. The maximum rise was between 1921 and 1925, the rate of increase diminishing after 1925 to 1928 or 1930. The only definite exception to the above is G.U. in males over 40 in Scotland.

*Absence of Falls after Rises.*—Rates which rose were subsequently maintained at the maximum level.

*Age Incidence.*—Rises are almost confined to age groups over 40 years. Age groups under 40 years show little change between 1912 and 1938.

*Sex Incidence.*—(a) The rates for females, both over and under 40 have shown little or no tendency to rise between 1912 and 1938. (b) G.U. in females under 40 has fallen to a very low rate, in continuation of a decrease which began in previous decades. The ratio of males to females has consequently been rising rapidly.

The rise in rates for peptic ulcer for the population over 20 years has thus been due almost entirely to males over 40.

*Gastric and Duodenal Ulcer.*—The death rate for G.U. throughout the period is considerably in excess of that for D.U. for both sexes and age groups and all areas, except for males in Scotland after 1927. Gastric ulcer showed a slow rise up to 1938 in males over 40 in England. The rise was rapid in the last few years in Scotland. For duodenal ulcer the rate became practically stationary in all age and sex groups and all areas after 1930.

*Areas.*—Death rates for peptic ulcer are highest in London, slightly lower for Scotland, lower for England, and lowest for Rural Districts of England. These differences are mainly due to rates for males over 40. Differences are slight for males under 40 and for females, in which groups rates are low. *Scotland:*—The trend of the rates for G.U. in males over 40 is entirely different from those for England and constituent areas of England. For D.U. in males over 40 the rise was extremely rapid between 1921 and 1931. *Rural Districts:*—The rates for males over 20 are approximately 60% of those for London and Scotland and 80% of those for England.

The March–April issue of *Industrial Welfare and Personnel Management*, the journal of the Industrial Welfare Society, contains an article on industry and rehabilitation by Dr. Harold Balm, medical officer in charge of rehabilitation, Ministry of Health, reviewing the work and progress of the movement, especially that part dealing with injuries which need not necessarily be permanent. Another article, on modern trends in industrial welfare, is by Sir Stafford Cripps, who discusses the modern conception of welfare based on the twofold contribution it can make to the social well-being of the worker and to efficiency of production.

## TREATMENT OF GAS GANGRENE

BY

J. D. MACLENNAN, M.D.

Major, R.A.M.C.; Officer Commanding a Mobile Bacteriological Laboratory

AND

M. G. MACFARLANE, Ph.D.

Secretary Anaerobes Subcommittee, Medical Research Council

The case-fatality rate of gas gangrene in the present war has been approximately 50%. Even with the low incidence found in desert warfare the disease accounts for a considerable proportion of the deaths from wounds (Pulvertaft, 1943; Wiles, 1944), and becomes a more serious problem when the incidence rises, as it is already known to have risen, with fighting in cultivated lands. The disease develops so soon after wounding and runs so swift a course that there is perhaps a tendency to regard this high death rate as an inevitable consequence of the delays and difficulties of treatment in the field. It is of course true, with long or difficult lines of evacuation, that in a large proportion of cases the patients may be admitted to hospital with the disease already established, but it is the object of this report to show again, from the case records of gas gangrene in the Central Mediterranean Force, that on the whole the fate of the patient depends on the treatment given by the clinician.

## Sources of Information

Information on the occurrence and treatment of gas gangrene is available from two sources: first, from a personal investigation carried out by one of us (J. D. M.); and, secondly, from the case reports on Army Form I 1241, which have been analysed by the other (M. G. M.).

**Field Observations with Eighth Army from July to Dec., 1943.**—Information on the anaerobic infections in Sicily is meagre. The observer was engaged primarily on other duties; furthermore, casualties were evacuated to hospitals as widely separated as Alexandria and Algiers, so that adequate follow-up was impracticable. From subsequent discussion it is thought that the 43 cases personally known represent from one-half to two-thirds of the cases occurring. The figures obtained in the Italian campaign are believed to be accurate and complete; they are for the Eighth Army only, and do not include cases among British troops in the Fifth Army. The diagnosis of gas gangrene, it may be added, has been made only on the unequivocal demonstration of a clostridial myositis.

**Analysis of Case Reports on Army Form I 1241.**—Clinicians were asked to report on this form not only cases of gas gangrene but also cases of lesser anaerobic infections. Actually the cases reported have varied greatly in nature and severity, but the differential diagnosis between gas gangrene of muscle and macrobic cellulitis has not always been explicit, and in some cases the recorded diagnosis was obviously open to question. It is necessary, therefore, in order to evaluate the effect of any line of treatment, to classify the cases on as uniform a basis as possible according to the recorded signs and severity of the illness, in spite of the obvious drawbacks in making such a classification from written records.

Out of the 173 completed reports on Army Form I 1241 referring to battle casualties in the C.M.F. received by the Medical Research Council by March 20, 1944, 126 were considered to be typical of cases of gas gangrene of muscle.

**Correlation of Results.**—It is known that the number of cases of gas gangrene which are reported on Army Form I 1241 is considerably lower than the number which have actually occurred, but, provided that the cases are not selected in any way, analysis of the reports should give a fair indication of the fatality rate and of the value of certain lines of treatment. The possibility of selection has been assessed by comparing the numbers and fatality rates of the cases reported on the forms and classified as gas gangrene with the corresponding figures for the same period obtained by personal investigation in the field.

In Table I are shown the figures for three periods in which the cases reported on Army Form I 1241 from the M.E.F. before and after El Alamein, and from Sicily, are covered

also by MacLennan's investigation. Though roughly only 50 to 60% of the known cases were reported, the case-fatality rates are not significantly different, both sets of figures showing

TABLE I

Campaign	Army Forms			MacLennan		
	Cases	Deaths	Fatality %	Cases	Deaths	Fatality %

Italy, Jan.-Feb.	31	15	48.4	—	—	—

\* Eighth Army only.

a reduction in the death rate in Tunisia and a considerable increase in Sicily. It appears, therefore, that the cases reported from a particular front were in fact a fair sample of those which occur on that front.

The position in the next three periods is different, since reports on Army Form I 1241 were received from the Fifth and Eighth Armies, while MacLennan's figures cover the Eighth Army only, up to the end of December. Here again the case-fatality rates in the two sets of figures are very similar, showing the persistence of a high death rate in the Italian campaign until the end of November and a somewhat abrupt fall in December. Though there is a tendency for the Eighth Army rate to be lower than the combined rate, the reduction was not in fact confined to the Eighth Army, for the cases reported in the last period, during January and February, were mainly from the Fifth Army.

It seems fair to conclude that the assessment of any line of treatment is not vitiated by any selection, on clinical grounds, of the cases reported. The main reason for the discrepancy between the number of cases reported and the number which occurred is that owing to the pressure of circumstances comparatively few reports were received of cases which were treated in advanced field units.

## Bacteriology

No complete survey of the anaerobic wound flora was undertaken in Sicily or Italy, but the consensus of opinion among pathologists in the C.M.F. was that it was very similar to that observed in Tunisia—i.e., that approximately 60% of the wounds contained clostridia, of which *Cl. welchii* and *Cl. sporogenes* were the predominant types. The findings in 17 consecutive cases of gas gangrene personally examined in Italy are very similar to those recorded from the Western European battlefields in 1917-18 and Tunisia in 1943:

TABLE II.—Organisms Isolated from 17 Cases of Gas Gangrene

<i>Cl. welchii</i> ..	14	<i>Cl. histolyticum</i> ..	1
<i>Cl. sporogenes</i> ..	8	<i>Cl. sporogenes</i> ..	10
<i>Cl. septicum</i> ..	4	<i>Cl. tertium</i> ..	10
<i>Cl. bifementans</i> ..	6	Other clostridia ..	10

## Fatality Rate and Treatment of Gas Gangrene

**Fatality Rate in Various Categories.**—The cases reported on Army Form I 1241 have been grouped in four categories, according to whether or not the disease was already established on admission of the patient to hospital and whether or not antitoxin was given in treatment (Table III).

TABLE III.—Cases Reported on Army Form I 1241

Therapy	Established on Admission		Developed in Hospital		Total		
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Rate %
No antitoxin	4	16	14	20	20	18	90
With antitoxin	42	25	64	35	106	60	56.6
Total	46	29	80	49	126	78	62.0

More than 60% of the cases developed in hospital, but the death rate in this group was as high (61%) as in those in which the disease was established on admission. The high death rate cannot therefore be ascribed solely to the long lines of evacuation. Moreover, although the cases treated with anti-

oxin show a reduced fatality rate, the actual rate (56.6%) compares unfavourably with the corresponding rate in the M.E.F. in Libya and Tunisia (31.8 and 22.4%). This fact raises the question of the efficiency of the treatment. Antitoxin therapy is only likely to be effective, in the first place, if the antitoxin given neutralizes the toxin of the infecting organism. It appears from Table II that, of the species of the gas gangrene group at all frequently isolated, *Cl. bifermentans* is the only one against which the trivalent antitoxin used (*welchii*, *oedematis*, *septicum*) would not be effective. Only one case of gas gangrene was diagnosed as due to this organism, and the infection ran a subacute course (MacLennan, 1944b). It seems fair to conclude that the antitoxin used was inherently effective against the prevailing infections. In the second place, treatment with antitoxin is only likely to be effective if it is given early, in adequate dosage, and as an adjuvant to surgical measures. It follows that in judging the efficiency of treatment as a whole, the efficiency both of surgical treatment and of antitoxin therapy must be considered. Since it has been previously shown that in cases receiving comparable surgical treatment the fatality rate was significantly reduced in the group who also received antitoxin (Macfarlane, 1943) it is not considered necessary to demonstrate this again, especially as the figures in Table III constitute *a priori* evidence of the value of antitoxin. The treatment given has therefore been graded in three classes, according to the level of the combined treatment.

1st class: Treatment within 6 hours of diagnosis, including surgical measures and an initial dose of at least 50,000 units of polyvalent antitoxin intravenously.

This is essentially the treatment which has been recommended by the War Wounds Committee (M.R.C. War Memorandum No. 2, revised edition, 1943). Prompt surgical measures of a temporary nature, such as incisions to relieve tension, were included in this class.

2nd class: Treatment delayed more than 6 hours after diagnosis, or with a smaller dose or an intramuscular dose of antitoxin.

3rd class: No surgical treatment and/or no antitoxin.

The fatality rates in these classes for the cases reported on Army Form I 1241 and also for the cases personally investigated are shown in Table IV.

TABLE IV

Treatment	Army Forms			Eighth Army		
	Cases	Deaths	Fatality %	Cases	Deaths	Fatality %
Class 1	35	12	34.2	27	9	33.4
Class 2	58	35	60.4	43	25	58.2
Class 3	33	31	90.4	8	8	100.0

It is clear that when the recommended treatment was given as soon as was practicable the fatality rate was significantly lower than when treatment was delayed or inadequate. The effect is still more striking in those cases in which the disease developed after admission of the patient to hospital, where it is possible that the diagnosis was made at an earlier stage of the disease. The fatality rate in this group (Table V) was only 22%; moreover, 2 out of the 4 deaths were considered to be due to complicating factors, the men having recovered from the acute stage of the disease.

TABLE V.—Cases from Army Form I 1241

Treatment	Established on Admission			Developed in Hospital		
	Cases	Deaths	Fatality %	Cases	Deaths	Fatality %
Class 1	17	8	47.0	18	4	22.2
Class 2	20	12	60.0	38	23	60.6

**Fatality Rates at Different Phases of the Campaign.**—It will be seen from Table I that the fatality rate in Sicily and in the first three months of the Italian campaign was very high but since November has been appreciably reduced. At the same time there was an improvement in the level of treatment, for the proportion of patients receiving first-class treatment, as defined above, rose from less than 20% to more than 40%, and the proportion receiving the third class of treatment fell.

It is noteworthy that the reduction in the fatality rate took place during bitter winter fighting and at a time when the

TABLE VI

	Army Forms				Eighth Army			
	No.	% of Cases			No.	% of Cases		
		Class 1	Class 2	Class 3		Class 1	Class 2	Class 3
Sicily	31	10	58	32	48	—	66	14
Sept.-Nov.	43	23	47	30	20	—	37	—
Dec.-Feb.	52	42	39	19	57	—	—	6

difficulties and delays of evacuation were more serious than in the early part of the campaign. It appears, therefore, that the reduction is directly related to the improvement in the level of treatment. In the Eighth Army this is attributable both to increasing experience among the many surgeons newly posted from the United Kingdom and from North Africa, and also to the active supervision of the Consulting Surgeon, Eighth Army, which led to a great improvement in surgical practice in forward areas.

### Comment

Although in recent years stress has rightly been laid on the value of antitoxin therapy and chemotherapy, these measures are no substitute for adequate operative treatment; the intelligent combination of all three measures can alone ensure success. It has not been possible in this and in other series of cases to assess the value of sulphonamides, which up to the present have been the drugs commonly used in treatment; practically all patients have received them, and it is probably fair to assume that they are of some, though clearly not of striking, benefit. The point which we wish to emphasize is that when two measures which are inherently of value in the treatment of gas gangrene—i.e., surgical measures and antitoxin therapy—were instituted with speed and efficiency, the case-fatality rate was very substantially reduced. With an increased use of drugs which are more effective against clostridia than the sulphonamides alone (such as penicillin or proflavine-sulphathiazole mixtures) in addition to these two measures, a further decrease in the fatality rate may be expected.

### Administration of Antitoxin and Drugs

**Antitoxin** should be given as early as possible in the disease; the time-honoured custom of delaying its administration until after operation has nothing to recommend it and may do incalculable harm. The route of choice is the intravenous; the dosage will vary with the clinical signs, but should not be less than 50,000 units of the polyvalent antitoxin, and if the patient is at all toxic it should be 100,000 units or more. A similar dose may be given in four to six hours if thought necessary. A decrease in pulse rate is usually a reliable sign of diminishing toxæmia. It is preferable to give the antitoxin in small volume rather than spread out the dose over many hours in an intravenous drip. This is especially important in the early stages of the disease, when the antitoxin should always be given by syringe. Acute anaphylactic reactions have been extremely rare.

**Penicillin** was used in three cases personally observed, as follows:

- (i) **Initial dose**—24,000 units of sodium penicillin intramuscularly given on the operating-table.
- (ii) **Three hours later**—sodium penicillin in a slow intravenous drip at the rate of 5,000–6,000 units an hour; continued for 24 to 48 hours.
- (iii) The usual dose of polyvalent antitoxin (50,000–100,000 I.U.) was given intravenously, and repeated if necessary.

In our experience\* this was found satisfactory. Little difficulty was encountered in giving the penicillin in a continuous drip transfusion. No reactions were observed, and the results were most encouraging.

### Prophylaxis with Antitoxin

The routine use of antitoxin as a prophylactic was recommended in Italy, the suggested dose being 16,500 I.U. of the

\* These observations were made in conjunction with Lieut.-Col. J. S. Jeffrey, Surgical Penicillin Officer, who is continuing the work.

polyvalent antitoxin, given intramuscularly to casualties considered prone to gas gangrene—i.e., those with severe wounds of the buttock, thigh, or shoulder, with compound fractures of the femur, or with penetrating wounds in which primary surgical treatment had been delayed more than 24 hours. From personal observations and from a knowledge of the amount of antitoxin used, we feel confident that these instructions were conscientiously carried out.

Between 13 and 14% of all battle casualties received prophylactic antitoxin. This figure, which is rather higher than had been anticipated, is based on an analysis of the operation books and records of nine surgeons who were working in the forward areas throughout the period in question, and involves 2,438 entries. There is no reliable information concerning the average time between wounding and the administration of the antitoxin, but since antitoxin was never given in front of the forward surgical centres, some estimate can be made on the basis of the average operative delay. The limiting times in the present series were 5½ hours and 3 days 6 hours, but the great majority of the patients were first seen by the surgeon in the 12-24 hours period after wounding. From a single run of 256 casualties admitted in a 36-hours period to one C.C.S., 26 received prophylactic antitoxin at an average time of 20 hours after wounding, and this is probably a very fair figure for the entire campaign.

It was not possible, in field conditions, to obtain the data which would show whether the administration of antitoxin had reduced the incidence of gas gangrene among those who were most likely to develop it, but one very interesting fact was observed. Full details are available concerning 75 out of the 78 cases occurring in the Eighth Army between Sept. 1 and Dec. 31, 1943. In 34 patients who received prophylactic antitoxin the mean incubation period of the disease was 68 hours; in 41 patients who had not received antitoxin (presumably because they were not considered likely to develop gas gangrene) the mean incubation period was 33 hours. This marked increase in the incubation time of the disease in the patients who had received antitoxin is at least indicative of the value of prophylaxis, particularly in view of the delay in administration; it may be recalled that the decrease in the incidence of tetanus upon the introduction of prophylactic tetanus antitoxin was accompanied by an increase in the incubation time in those who developed the disease.

#### Summary

Cases of gas gangrene occurring in the Central Mediterranean Force between July, 1943, and February, 1944, have been studied both in the field and by an analysis of Army Form I 1241.

The fatality rate, which was high in Sicily and in the early part of the campaign, fell sharply in December, 1943. It has been shown that this fall was coincident with an improvement in the general standard of treatment.

The case-fatality rate was lowest among those who received within 6 hours of diagnosis both surgical treatment and an intravenous dose of at least 50,000 units of polyvalent antitoxin.

Some evidence indicative of the value of antitoxin as a prophylactic has been presented.

Thanks are due to the D.G., A.M.S., for access to the case reports, to D.D.M.S. and Consulting Surgeon, Eighth Army, for the granting of facilities for the field investigation, and to Dr. E. Lewis-Fanning for his help with the analyses.

## FRACTURE OF THE CARPAL SCAPHOID

BY

JEFFREY M. ROBERTSON, M.B., B.S.

*Surg. Lieut.-Cmdr. R.N.V.R.*

AND

R. D. WILKINS, M.R.C.S., L.R.C.P.

*Surg. Lieut., R.N.V.R.*

In the practice of the fracture clinic at a Royal Naval hospital during two and a half years of war we have been impressed by the frequency of fracture of the carpal scaphoid in the young healthy adult male. This article is an analysis of our experience of this lesion. We also make a very strong plea for the recognition of this important drain on man-power. By early diagnosis and adequate treatment prolonged disability can be avoided and many useful men returned to duty who otherwise would waste many months in invalidism. Wilson states that 86% of carpal injuries involve the scaphoid. Hook and Boone (1936), of the United States Naval Service, in their analysis quote figures of one in ten compared with other carpal injuries. Unfortunately most recorded figures do not state the types of lesion included. Our own series includes only fractured scaphoids and Colles fractures.

In the period under review there have been treated at this hospital 100 fractured scaphoids, compared with 58 Colles fractures. The patients have all been sailors or airmen between the ages of 17 and 50, the average age being 27 years. Many of these men had received an injury at sea or on an isolated station with no facilities for radiological examination. We would urge that had they all been treated as possible fractures from the start and been immobilized, much loss of valuable time would have been avoided.

#### Aetiology

Scaphoid fracture has almost always been caused by a fall on the outstretched hand or a forced and unguarded dorsiflexion of the wrist. A number of cases have come to our notice with a history of recent injury but with the radiological findings of an old ununited fracture of the scaphoid. These men had been able to carry on for years with no other symptoms than a slight weakness of the wrist. It is considered that the real cause of their disability is the lighting-up of osteo-arthritis consequent on their original injury, rather than on the fracture *per se*.

#### Symptoms and Signs

These may be no more than a "sprain" of the wrist, and herein lies the potential danger of overlooking a fracture. It is a platitude, for the repetition of which no apology is given, that all sprains should be x-rayed if possible and all doubtful cases treated as fractures.

The nearest approach to classical signs of scaphoid injury are pain, tenderness, and swelling in the "anatomical snuff-box." Another sign sometimes obtained is pain on percussion of the tip of the thumb held in extension. In the presence of these signs, even if the radiological findings are negative, nothing is lost by immobilization for a fortnight in plaster-of-Paris. Radiological examination at the end of this time will clearly demonstrate a fracture if present, and a very valuable fortnight of immobilization will have been gained.

#### Radiology

These fractures can be extremely difficult to demonstrate, especially in the early stages. It is our practice to take four views of the bone—i.e., antero-posterior, lateral, and the two obliques. The commonest site of injury is across the waist of the bone, and it is here that a most careful search must be made.

The earliest lesion may show only a "hair-line" crack. This can sometimes be made more obvious by forced ulnar deviation of the wrist, which tends to open the crack in the scaphoid by the pull of the medial collateral ligament. After ten days the crack may become more obvious owing to the physiological hyperaemia of repair producing osteoporosis. Herein lies the importance of a later radiograph in doubtful cases of sprain. This osteoporosis may in a small number of cases progress to

R. C. Murphy (*New Engl. J. Med.*, 1944, 280, 69) records a case of Stevens-Johnson's disease—an eruptive fever involving the mouth and eyes, described in 1922. It is characterized by an acute, sometimes fulminating, onset with fever and prostration, erythematous generalized rash, and severe stomatitis followed by sloughing. With occasional exceptions the conjunctivae are involved. The usual period until resolution of the skin lesions is about three weeks. Nothing has been revealed by laboratory examination. The age limits are 22 months to 16 years. With rare exceptions the disease is confined to male children.

a cystic appearance in the middle of the bone (Fig. 1), and should be completely reossified before union can be considered secure. It should not be mistaken for a similar cystic appearance throughout the bone which is sometimes seen in men who use traumatizing tools—e.g., pneumatic road drills or

FIG. 1.—Typical cystic appearance sometimes seen in the fracture line during the process of repair, due to hyperaemic decalcification.

FIG. 2.—Multiple carpal cysts with pathological fracture of right carpal scaphoid. Patient a dockyard worker who had used a small pneumatic drill over a long period. Drill required support of right hand only. No bony abnormality of left carpal bones.

riveting machines (Fig 2). A less common and not so important injury, demonstrated radiologically, is a separation of the tubercle of the scaphoid.

In cases with delayed union varying degrees of avascular necrosis of the fragments, sclerosis of the fracture edges, and osteo-arthritis will be demonstrated. This necrosis must not be confused with the avascularity of the proximal fragment compared with the osteoporosis of the more richly vascularized distal portion of the bone that is sometimes seen. This imbalance is noted chiefly at about the second month, and tends to be restored as healing proceeds. In cases in which union has been long delayed this avascularity may persist and remain with consequent destruction of the articular cartilage and the laying of the foundations of osteo-arthritis.

Treatment

It has been our practice to immobilize in plaster-of-Paris all cases of suspected scaphoid injury. This routine is carried out in both the early and the late cases, whatever the radiological findings may be. By adopting this measure early cases are not overlooked, and those late cases that will unite with immobilization are given a chance of doing so. As stressed by Watson-Jones, this immobilization must be adequate and continuous, and be prolonged until either complete union has taken place or non-union has become established.

The type of cast used is an unpadded plaster from the upper forearm to the metacarpal heads. Slight dorsiflexion,

with the thumb in line with the long axis of the radius and slight radial deviation, is the position of choice (Fig. 3). For a period we exaggerated these positions, as recommended by Buxton, but found that thereby the discomfort of the patient was considerably increased without there being a corresponding improvement in healing-time. The first metacarpo-phalangeal joint is immobilized, and on the palmar surface the plaster is brought only to the proximal crease in order to allow full flexion of the fingers. Care is taken to mould well into the palm to ensure no movement in the carpus.

At this point we would stress the importance of impressing on patients the need for continuous immobilization. The least crack or weakening of the plaster must be at once reported and put right.

FIG. 3.—Type of cast and position of thumb.

Results

Of our cases 52 were diagnosed and treated within seven days of injury, and all of them had clinical and radiological union, with an average period of immobilization of 11.16 weeks (Table 1). All cases were checked by further radiological examination a fortnight after removal of the plaster.

TABLE 1.—Results of Plaster Treatment

	No. of Cases	Union	Non-union
Treated within 7 days of injury	52	52	
United plaster-of-Paris only; average time, 11.16 weeks			
Treated after 7 days of injury	48	13	
United plaster-of-Paris only; average time, 26 weeks			
Ununited:			2
Severe osteo-arthritis and invalided ..			3
No osteo-arthritis and sent to duty ..			12
Slight osteo-arthritis and sent to light duty ..			8
Operation and duty or light duty ..			3
Operation and invalided ..			1
Operation disposal unknown ..			6
Final state and disposal unknown ..			
	100	65	35

Of the remaining 48 cases—all of which were seen at periods ranging from one week to several months or even years after injury—a further 13 united with plaster only, but with an average immobilization period of 26 weeks. The longest period of immobilization resulting in union was 60 weeks. Patience in this case was indeed a virtue well rewarded. Established non-union occurred in 29 of these late cases. By this we mean radiological separation of the fragments with marked sclerosis of the fracture edges (Fig. 4). This may often be associated with avascular necrosis of the proximal fragment. Of these cases, two were discharged from the Service as unfit for any further work involving the wrist. Details of these two cases are given to show the lamentable story which may follow a missed diagnosis of this very amenable lesion.

**Case 1.**—This patient, aged 41, was diagnosed as having a fractured scaphoid five months after injury. Two and a half years' immobilization in plaster was employed, during which three unsuccessful bone-graft operations were performed at an E.M.S. orthopaedic hospital. Advanced osteo-arthritis and severe disability resulted.

**Case 2.**—The patient, aged 37, was first seen five years after injury. There was then a good deal of sclerosis, and non-union had resulted. The wrist was immobilized for 40 weeks with no improvement, and osteo-arthritis and severe disability resulted.

In three cases of non-union the men were discharged to full duty. These were all late cases, but had been fortunate in having a good range of movement and no osteo-arthritis.

FIG. 4.—Established non-union with marked sclerosis of both fragments and early osteo-arthritis change.

changes. In 12 cases of established non-union which had no other treatment than prolonged immobilization the men were discharged to light duty. Most of these cases showed some degree of osteo-arthritis and disability of the wrist; these patients were all men who were especially valuable to the Service by reason of technical knowledge and experience.

Twelve cases of non-union received operative treatment. These operations were performed at various hospitals; the results are set out in Table II. It will be noted that union was obtained in a further five of these cases; two had osteo-arthritis changes. Three of the five returned to duty; one was invalided owing to the severity of the disability; and the disposal of the fifth is unknown. The two cases of excision of the proximal fragment developed osteo-arthritis, but were fit for further service. Of the remaining five, two had to be invalided with non-union and arthritis and three went to light duty with non-union and arthritis.

TABLE II.—12 Operation Cases

Type of Operation	No.	Total Treatment Period	Result	Osteo-arthritis	Disposal
Bone graft	3	(i) 32 weeks	Union	Absent	Duty
		(ii) 40 "	"	Present	Invalided from Service
		(iii) 52 "	Non-union	"	
Excision of proximal fragment	2	(i) 20 weeks	"	"	Duty
		(ii) Not known	"	"	Light duty
Drilling	7	(i) 32 weeks	Non-union	"	Light duty
		(ii) Not known	"	"	Invalided
		(iii) 36 weeks	Union	Absent	Duty
		(iv) 68 "	"	Present	Invalided
		(v) 16 "	Non-union	"	Light duty
		(vi) 16 "	Union	Absent	Not known
		(vii) 20 "	Non-union	Present	Light duty

Thus it is shown that operative treatment is essentially a last resort and the results may be disappointing. The chief reason for this is the apparent inevitability of osteo-arthritis changes.

The records of the remaining six cases of the series cannot be traced, and they are included only to show the relative frequency of the scaphoid lesion in wrist-joint injuries.

TABLE III.—Final Results in the Series of 100 Cases

United	Disposal:	Cases
73	27	100
Returned full duty	72	
Returned light duty	16	
Invalided	5	
Final disposal unknown	7	

#### Multiple Carpal Fractures associated with Fractured Scaphoid

Two cases were associated with Colles's fracture of the lower end of the radius. There was one case of bilateral fracture of the scaphoid caused by falling backwards on to both wrists. One united in three and the other in four months. There was one case of fracture of the tubercle of the scaphoid together with fracture of the os magnum. Sound union occurred in nine weeks. One case of fracture of the body of the scaphoid occurred together with fracture of the trapezium and trapezoid. Prolonged immobilization was unsuccessful, and osteo-arthritis of the carpus resulted. One fractured scaphoid tubercle was associated with a Bennett's fracture, and both united in six weeks.

An unusual case was seen in a man aged 35 whose case was diagnosed one week after injury as a fracture of the waist of the scaphoid. After three months' immobilization union had taken place. He continued to have a painful wrist, and two months later developed a cold abscess in the region of the scaphoid. This was aspirated and proved to be tuberculous. There were radiological findings of tuberculous disease of the scaphoid, and he was transferred to an E.M.S. hospital for further treatment.

#### Summary

An analysis of 100 cases of fractured scaphoid in a continuous series of 153 wrist-joint injuries is given.

The importance of not overlooking injury to the carpal scaphoid in young adults with "sprained wrist" is stressed.

The value of early and adequate plaster-of-Paris immobilization is proved, and a plea is urged for early plaster even in the absence of radiological facilities or positive diagnosis.

Operation in a small number of late cases may preserve some utility in the affected wrist.

We wish to thank Surg. Rear-Admiral Twigg for kind permission to publish this paper. We are also very grateful to Miss Irene Lindsay, V.A.D., for invaluable assistance in collecting and compiling our records, and are indebted to Surg. Cmdr. Pankridge for his assistance with the radiology.

## EPIDEMIC INFECTIVE HEPATITIS IN GLOUCESTERSHIRE

BY

J. S. COOKSON, M.D., D.P.H., Barrister-at-Law  
Deputy County Medical Officer of Gloucestershire

Although infective hepatitis is not at present a notifiable disease, as many as 246 cases were reported in Gloucestershire during 1943. Most of these occurred in children attending elementary schools, the remainder in children in residential nurseries; and the behaviour of the disease was so different in the two types of community that it seemed worth recording. It is hoped that the outbreaks in residential nurseries will be of some epidemiological interest, since children and staff seem to make, so far as is practicable, a closed-herd community. Lisney (1937) and Newman (1942) have described outbreaks in schools, and Evans (1942) and Hallgren (1942) have recorded outbreaks in institutions which are practically closed communities.

#### Observations

##### (a) Elementary Schools

From elementary schools with a total attendance of 40,000 the number of cases of infective hepatitis reported during the

year was 224. These cases were distributed among 59 schools. The usual means of spread was exemplified by an outbreak at Picklenash School, Newent, where out of 411 children some 46 were infected during the year. In the early stages only occasional single cases occurred at intervals of one or several months (when the infection was presumably smouldering), and it was not until April, 1943, that the outbreak took on epidemic proportions.

Chart of weekly incidence of cases at Picklenash School, Newent.

The epidemic ran its course in much the same manner as other recorded outbreaks. The infection was scattered throughout all classes, and no particular age group and neither sex was specially affected. The incubation period, determined from the onset of the first case to the next one in the same family, was about four weeks. It is, of course, realized that an incubation period determined in this way is only the maximum, since clearly the first case was infectious after the onset of symptoms and signs. In accordance with regulations, the head teacher excluded home contacts for four weeks from the date of last contact with a case before the latter's release from isolation. In addition he used his discretion in regard to suspicious cases, usually excluding these for a week and then readmitting them if no jaundice had developed.

#### (b) Residential Nurseries

Outbreaks of epidemic infective hepatitis occurred in two residential nurseries, and the infection attacked the children in an entirely different manner from that noted in the elementary schools. In the Stanley Park Residential Nursery no cases had previously been recorded, and then suddenly, out of a population at risk of 41 children and 16 staff, some 9 children were affected within the course of 14 days.

TABLE I.—Stanley Park Residential Nursery

Case	Sex	Age	Date of Onset	Vomit	Diarrhoea	Constipation	Jaundice: Day of Onset	Dark Urine	Pale Stools
1	M	4	2/10/43	+	—	+	3	+	+
2	F	3	4/10/43	+	—	—	3	+	+
3	M	1	6/10/43	+	—	—	4	+	+
4	M	1	7/10/43	+	—	—	1	+	+
5	M	2	8/10/43	+	—	—	2	+	+
6	F	3	9/10/43	—	+	—	1	+	+
7	F	2	12/10/43	—	+	—	1	+	+
8	F	2	14/10/43	—	+	—	3	+	+
9	F	2	15/10/43	+	—	+	4	+	+

In the Bownhill Farm Residential Nursery no cases had occurred previously, and then, out of a population at risk of 25 children and 11 staff, 11 children and 1 of the staff were affected within 11 days. No other cases occurred other than

TABLE II.—Bownhill Farm Residential Nursery

Case	Sex	Age	Date of Onset	Vomit	Abd. Pain	Diarrhoea	Constipation	Jaundice: Day of Onset	Dark Urine	Pale Stools
1	F	3½	10/11/43	—	+	—	—	5	+	+

11	M	3	21/11/43	—	+	—	—	2	+	+
12	F	1	21/11/43	—	—	—	—	2	+	+
13	F	17	7/12/43	—	—	—	—	6	+	+

a member of the nursery staff who developed the disease about a month after the onset of the last case among the children.

#### Clinical Course in Residential Nurseries

The children in the nurseries could be kept under close observation, and it was possible to make a day-to-day record of the course of the disease. In most cases there was no difficulty in diagnosis: typically the illness started with an attack of vomiting and a moderate rise of temperature, but in one case the temperature rose to 106.8° F. Dark urine and pale stools were usually present the day before the jaundice appeared. This generally developed about the third day of the disease, but in some cases it appeared as early as the first day and in others as late as the seventh day. When the children developed jaundice they usually began to feel better. A rash was not uncommonly present. As a rule this was urticarial, probably caused by scratching as a result of skin irritation, but in a small number of cases a maculo-papular rash appeared across the back of the shoulders on the sixth day and later extended to the abdomen. The rash came out quickly, and faded gradually over several days.

#### Epidemiological Features

##### (a) Elementary Schools

For several years occasional sporadic cases of infective hepatitis have occurred in widely separated parts of Gloucestershire, but not until 1943 was the incidence in any one place so high as to merit the disease being described as epidemic. Since the disease is not notifiable, the recorded cases form only a small percentage of the total number, as the disease was widespread and school-children were by no means the only age group affected, but they give a general indication as to distribution. In the urban areas the disease did not seem as prevalent as in the more sparsely populated areas. Two new factors, however, have possibly facilitated its rapid dispersal—the fact that in many villages war workers are now taken from their homes to their factories each day by motor-bus, and also that the older children are collected from their homes and taken to senior schools daily.

No difference clinically was noted between the sporadic and the epidemic cases. When the first case occurred in an elementary school there seemed to be no way of telling whether it would be the only case or whether a substantial number of other children would be affected. Presumably this fluctuation in attack rate must be due to the children's degree of susceptibility to infection and to some local environmental factors, which together favour or limit the spread.

In the outbreaks in the elementary schools the infection ran its anticipated course. Cases cropped up fairly regularly at approximately monthly intervals with occasional gaps of two months, infection presumably being from case to case with an incubation period of one month, missed or subclinical cases filling the gaps; this is not surprising in view of the mildness of some cases (Newman, 1942). This series of cases was, however, not at all the type to be expected if the infection was waterborne.

##### (b) Residential Nurseries

As has been stated, in both residential nurseries the outbreaks ran courses entirely different from those recorded in the elementary schools. In the Stanley Park Residential Nursery many of the children had suffered from an unfortunate outbreak of stomatitis about a month before the first case of infective hepatitis. But the children who subsequently had infective hepatitis were not necessarily those who earlier had stomatitis. Attention is drawn to this, since other epidemics have been associated with certain nasopharyngeal conditions. Glover and Wilson (1931) describe an outbreak associated with sore throats, and McFarlan (1941) records an outbreak associated with measles. Assuming the usual long incubation period of one month (Pickles, 1939), it is impossible to explain this type of outbreak on the basis of case-to-case spread. It seems much more probable that the children received the pathogenic agent from a common source. The outbreak might be described as explosive. Superficially it had certain resemblances to a waterborne spread, but examination revealed the water to be of a satisfactory quality. After considerable

difficulty, information was elicited that a mother had visited the nursery 34 days before the onset of the first case. She had recently had jaundice, and had only been discharged from hospital several days previously. She spent a short time one afternoon playing with the children at the nursery, and it would seem probable that all the cases were infected from this one source. This degree of infectivity, even associated with a susceptible child population, is most striking.

In the outbreak at Bownhill Farm Residential Nursery there was again a resemblance to a waterborne epidemic. It seemed probable that the children had received the pathogenic agent from a common source, but I was entirely unable to trace a contact, either direct or indirect, with a known case of infective hepatitis. On examination of the water and the source of supply a remarkable state of affairs was found to exist. The water was gathered by pipes to a collecting chamber from three sources—A, B, and C. Sources B and C were still active, but source A had practically dried up. At the collecting chamber a pumping engine had been installed which pumped the water from sources B and C up the pipe to source A, which was now used as a reservoir, giving the necessary gravitation for the house supply. Since this source A was situated in a midden it was not surprising that the water showed a considerable degree of pollution. The gathering-ground of all three sources was carefully examined; but no human beings lived there, and only cattle and sheep were pastured on the ground. All that could be discovered was that the water was badly polluted, and further evidence would be required to show that this was the cause of the outbreak. Although an outbreak of waterborne epidemic infective hepatitis has been described by Hallgren (1942), it would need far more evidence than mere pollution of the water to prove conclusively that the children at Bownhill Farm Residential Nursery were infected by the water supply. There is also the marked similarity to the outbreak at Stanley Park Residential Nursery, where the disease was shown to be introduced by an infected person.

#### Summary and Conclusions

A short epidemiological account is given of 246 cases of infective hepatitis which occurred in Gloucestershire in 1943.

An outbreak is described in an elementary school, where the infection ran its expected course.

This is contrasted with the outbreaks in two residential nurseries, which were explosive in type, infection probably being from some common source.

In one residential nursery the source of infection is presumed to be an infectious visitor, 34 days before the first case.

In the other residential nursery no such contact was found; the possibility of the infection being waterborne is discussed, but is rejected.

A brief clinical account is given of the children infected with infective hepatitis in two residential nurseries.

I am indebted to Dr. H. K. Cowan, County Medical Officer, for his help and for permission to publish the results of these investigations.

The Surrey Hospitals Divisional Council, formed under the auspices of the Nuffield Provincial Hospitals Trust, has widened its area to include the county borough of Croydon, four of whose representatives now participate in the Council's work. This inclusion has eased the task of the Planning Committee, which has issued a draft scheme for the co-ordination and extension of the hospital services in the county. The scheme includes key, main, and local hospitals, specifying the proposed functions of each and suggesting the minimum services and departments which might reasonably be expected. The greatest shortage of accommodation is in the north-west section of the Council's area, where no hospital exists which could perform the functions of a main hospital. The draft plan has been sent to the constituent bodies—that is, the various hospitals in the county, the local authorities, and a number of voluntary organizations, central and local—for their observations. A survey of maternity accommodation and of special hospitals is now being undertaken.

## EXPERIMENTS ON SCABIES PROPHYLAXIS

BY

KENNETH MELLANBY, Sc.D.

Major, R.A.M.C.

With our present knowledge there should be little difficulty in treating and curing all cases of scabies as soon as these are diagnosed, but a great advance would be made if we could discover a method of scabies prophylaxis which would prevent infection from taking place. Farmers have long been faced with a similar problem, and infestation of sheep by mites is kept under control and has even been completely eliminated in some countries by universal "dipping." So far it has not been possible to devise anything so satisfactory that is practicable for use with man, though Percival (1942) has suggested that the whole population of Britain might be simultaneously treated with sulphur ointment to try to eradicate the disease. For prophylaxis some method is needed which is safe, efficient, simple, and cheap.

An experiment was made to try, against human scabies, a standard sheep dip supplied by the Cooper Technical Bureau, as this is inexpensive and could be made available in large quantities. Having previously determined that immersion for three minutes could be well tolerated by most individuals, two men suffering from scabies were immersed for that period in a bath of sheep dip at a temperature of approximately 20° C. and then the liquid remaining on their skin was allowed to dry. Less than 50% of the mites were found to be dead after re-examination 24 hours later. As this method will not cure human scabies satisfactorily it can hardly be effective as a prophylactic. No doubt the satisfactory results obtained with sheep are due to the quantity of dip which remains in the wool and so in contact with the parasites.

I have little doubt that universal dipping with benzyl benzoate emulsion would prove completely successful in wiping out scabies. One experiment on these lines may be quoted. In a Midland mental hospital scabies presented a major problem among the female patients. Out of a sample of 183 which were carefully examined, 48 cases of scabies—i.e., 26%—were found. The treatment of scabies among these patients had presented a major problem to the staff for a long period. On two consecutive dates in September, 1942, the female patients (804 in all) were given a single treatment with benzyl benzoate emulsion, which was painted all over the body; the staff of the hospital were also very thoroughly examined and any positive cases treated. No bath was taken before the treatment. Since that date scabies has given no further trouble, and only a negligible number of cases had been found. This demonstrated conclusively that in a population showing a high incidence of endemic scabies a single treatment of all individuals will effectively wipe out the complaint; but, as will be shown below, it is essential that all the members of every household should be treated. Unfortunately there is available neither the benzyl benzoate nor the technical assistance to institute universal treatment, and, also, new legislation would be needed to ensure success.

We know that in human scabies the vast majority of the parasites are found on the hands and wrists (Johnson and Mellanby, 1942), and it was therefore thought that, instead of a universal programme of "dipping," it might be possible to obtain satisfactory results by treating this restricted area of the body with benzyl benzoate. Work on these lines was carried out among several groups, constituted as follows: (a) W.A.A.F. members of balloon crews; (b) school-children in a large county borough; (c) school-children in an urban borough; (d) school-children in what was technically a rural district but in which mining was the main industry. Unfortunately, Service requirements were such that the membership of the first group changed so frequently that no conclusive results could be obtained, but the school-children were all under observation for a considerable period.

#### Procedure with School-children

The same procedure was adopted for all the children concerned. On the first visit their hands and wrists were examined and those with *Sarcoptes* in burrows noted. In all these preliminary examinations it was possible to verify the diagnosis

y the removal of live parasites. The names of these children with scabies were reported to the School Medical Service, which took action regarding their treatment. Immediately after examining each child a quantity—approximately 1 c.cm.—of benzyl benzoate was placed on the palm of one hand, and this was rubbed into both hands and wrists without delay. This was repeated at approximately fortnightly intervals for twelve visits. Unfortunately for the possibility of assessing the experimental results in a simple manner, whenever a case of scabies was found it was necessary for it to be reported, and the child was excluded from school for treatment. This meant that the falling incidence might be due to two causes—either the action of the benzyl benzoate on the hands and wrists or the exclusion of chronic cases of scabies and the treatment of their families by the local health authorities. To try to get over this difficulty a "control" group of children was selected. Here the fortnightly inspections were made and infected children were excluded from school, but no prophylactic benzyl benzoate was used.

The results of this investigation, which incidentally necessitated over a quarter of a million individual examinations, are summarized in the accompanying Table. It will be seen that the incidence was reduced very considerably in every group.

Table showing Results of Visits and Treatment on the Incidence of Scabies

District	Number of Children Examined	Incidence of Scabies (%)		Final Incidence as Percentage of Original
		First Visit	Twelfth Visit	
(a) Benzyl Benzoate applied to Hands and Wrists				
County borough (industrial) ..	9,962	1.48	0.23	15
County borough (industrial and mining) ..	2,526	2.57	0.71	28
Rural " district (mainly mining) ..	536	2.10	1.13	54
(b) No Benzyl Benzoate applied				
County borough .. .. .	5,928	2.13	0.43	20

The most striking results were obtained from the county borough, and here the control group gives some further data. Considering the control group first, it is obvious that a great decrease in scabies was brought about merely by inspections, with subsequent treatment. A greater decrease took place in the group from the county borough where the hands and wrists were treated with benzyl benzoate. Dr. J. O. Irwin has kindly examined the detailed data of this experiment, and he finds that the decrease in incidence of the "treated" group was significantly greater than that of the "control"; but, even so, it is obvious that the extra trouble and expense of providing benzyl benzoate were very meagrely repaid.

#### Practical Conclusions from Experiment

The conclusion which may be drawn from this work with school-children is that frequent inspections by persons well used to recognizing scabies will serve to reduce the incidence of the disease very greatly provided that cases, when found, are treated speedily and efficiently, and provided that the whole family of each case is also treated. Even quicker results would be obtained, and many children would be saved from ever having scabies, if regular inspections could be made throughout the whole population. This may not be possible, but propaganda which will make people scabies-conscious and willing to seek proper treatment for themselves and their families as soon as they suspect scabies can have a similar result. Incidentally, the majority of the population seem still to rely on self-treatment with widely advertised "remedies" that are either quite useless or improperly used, so that no cure is produced and the spread of the disease continues (Graham, 1944).

One further point which emerges from this investigation is that it is very unlikely that children often contract scabies inside the school buildings. A statistical analysis of the incidence in the various classes reveals that cases were scattered entirely at random throughout each school without any significant concentration in any class. Furthermore, it was very rare indeed to find two cases of scabies in adjacent desks. There seems no doubt that scabies is caught out of school, mainly in the home, so that exclusion from school for this complaint is only essential because it is usually a necessary preliminary to ensuring proper treatment. If there is any delay

in starting the treatment then the child is unnecessarily deprived of a period of education.

The occurrence of scabies in the Services may give some clue to the possibility of preventing the spread of the disease in the rest of the population. Early in this war a great deal of scabies was found in the Army in Britain, and the incidence appeared to be higher than that among the civilian population. Further investigations showed that this was not in fact the case, and the discrepancy was due to the frequent medical inspection of soldiers, so that their scabies was discovered while civilians harboured the disease undetected. Furthermore, it seemed likely that most of the scabies in troops was derived from civilian sources and that little actual spread took place inside the Services. This view is supported by consideration of what happens among troops when abroad. Among British troops in North Africa, where there was very little contact between them and the civilian population, scabies was practically non-existent and only to be found among recent arrivals from this country. Among isolated troops with efficient treatment of cases as they arise the disease rapidly disappears. It must be remembered that scabies may have an "incubation period" of nearly two months (Mellanby, 1943).

The facts described in this paper indicate that prevention of scabies is by no means a simple problem. If we could treat the whole of any population with benzyl benzoate we could wipe out the disease, but this is practicable only among limited and isolated communities where the incidence is substantial. On the other hand, if we can treat only part of the population—e.g., soldiers on service without treating their families, or school-children without any treatment in the home—then complete control is impossible. Frequent inspections among a population aware of the danger of this disease, followed by proper treatment of the cases and all their contacts, seem the only universally satisfactory method. There is no short cut to the successful control of scabies.

#### Summary

Experiments necessitating a quarter of a million inspections of school-children suggest that scabies prophylaxis is not practicable, apart from the normal treatment of the disease. But frequent examinations by personnel experienced in the diagnosis of the disease will reveal numerous cases; their treatment and that of all contacts can rapidly reduce the incidence of scabies.

It is necessary to allow the districts in which this work was done to remain anonymous; therefore I cannot acknowledge personally my gratitude to the various local authorities, medical officers, and teachers whose co-operation made the investigation possible. Most of the examinations of children were carried out by pacifist volunteers who were subjects for various medical experiments at the Sorby Research Institute. The expenses of the investigation were met by the Ministry of Health and the Medical Research Council.

## Medical Memoranda

### A Case of Pneumococcal Meningitis Treated Successfully with Sulphathiazole

Although the recent literature contains records of the cure of pneumococcal meningitis by sulphonamides with or without serum, it was thought that the following case, successfully treated with sulphathiazole alone, might be of interest.

#### CASE RECORD

The patient, a postmaster aged 56, was in his usual good health when he retired to bed at 10.30 p.m. on May 8. At 2 a.m. next day he vomited, and at 4.45 a.m. was found in the lavatory in a dazed condition. He was put to bed, but became very restless and irrational, and at 6 a.m. was seen by his doctor and given morphine gr. 1/4. At 9.30 a.m. he was admitted to hospital, unconscious. On examination he was lying curled up on his left side, deeply stuporous and incontinent. His temperature was 100° F., there was slight neck rigidity, Kernig's sign was positive, and the pupils were small and equal and did not react to light. Apart from slight weakness of the right external rectus muscle, the cranial nerves appeared normal. The upper limbs were hypotonic but showed no paralysis; tendon-jerks were absent. The lower limbs were flexed, tone poor, knee-jerks diminished, and ankle-jerks present; the plantar response was extensor on the left side and flexor on the right. His pulse was 100, blood pressure 120/60; the apex beat

was half an inch outside the mid-clavicular line in the fifth intercostal space, and a few extrasystoles could be heard. Examination of the chest, abdomen, and ears revealed nothing.

Lumbar-puncture was performed and turbid fluid was obtained; pressure, 120 mm. water. It contained 2,000 cells per c.mm., of which 98% were polymorphonuclears. No bacteria were seen in a direct smear, but a Type 18 pneumococcus was grown in pure culture. A blood count showed a leucocytosis of 22,500, of which 83.5% were neutrophil polymorphonuclears. Treatment with sulphathiazole was begun at 4 p.m. on May 9. Since oral administration was impossible, the soluble sodium salt was given intravenously, the patient receiving 20 g. in 6 pints of glucose-saline in the first 24 hours. Subsequently oral administration was possible, and he received 18 g. by this route in the second 24 hours and 24 g. during the next 48 hours, making a total of 62 g. in 96 hours. After a restless night the patient improved considerably during the course of May 10, becoming fully conscious and fully orientated by 4 p.m.; his temperature was then 100° F. and eye movements were normal. On the 11th improvement was maintained; the pupils were normal and the chest clear. A herpetic eruption on the lips started at this time, becoming more severe and extending to the left cheek during the next two days; it was accompanied by stomatitis and glossitis. On May 14 the temperature had dropped to 98.4° F. and the C.S.F., which was under normal pressure, contained only a few degenerate polymorphonuclear leucocytes, and proved sterile even after cultivation in media containing *p*-aminobenzoic acid. The condition of his mouth was improving. On May 16 he had a shivering attack and, since recurrence is common in this disease, a further course of 30 g. of sulphathiazole was given during the next four days. He continued to improve, however, and by May 24 was convalescent. He was discharged well on June 14, and has since returned to work. A primary focus of his infection was sought, with negative results; a radiograph of the chest (May 25) and of the accessory air sinuses (June 3) revealed nothing abnormal, and no focus in the middle ear could be discovered.

I am indebted to Dr. W. A. Bullough, County Medical Officer of Essex and to Dr. O. W. Chapman, acting medical superintendent of the hospital, for permission to publish this case, as well as to Dr. C. F. Barwell, pathologist to the hospital, for the laboratory investigation.

C. GOING,

House-physician St. Margaret's Hospital, Epsom

## Treatment of Some Complications of Bacillary Dysentery

The sulphaguanidine treatment of bacillary dysentery has certain drawbacks. The drug is expensive and a large dosage is required; being an oral remedy, it is often precluded by vomiting in cases which need it most. Sulphapyridine has the advantage of being cheap, and it was found by Paulley to be at least as good as sulphaguanidine. More important is the fact that sulphapyridine and sulphathiazole have soluble salts which can be injected in urgent cases. That this advantage has not yet been exploited is due to the belief that the action of the sulphonamides in dysentery is exerted almost entirely within the lumen of the bowel.

We have now used sulphapyridine in the treatment of over 200 cases of bacillary dysentery in Lagos, injecting the drug intravenously in adults or intramuscularly into the scapular muscles in children whenever injection is indicated. Although our dysentery—practically all Flexner infections—might be expected to respond well to sulphonamides, it is often complicated by nutritional deficiencies of the vitamin B<sub>1</sub> complex. Gross signs of ariboflavinosis are very common in the adult population. Infantile pellagra ("kwashiorkor") is a deficiency syndrome of high mortality often occasioned by gastro-enteritis. Having found that undiluted milk could be taken with impunity as soon as sulphonamide therapy was established, we have given it in quantity to meet the demand for fluid and to supply the nutritional deficiencies. In urgent cases we have injected a crude liver extract to supply the B<sub>1</sub> complex. The results in simple cases were, as might be expected, invariably good. In complicated cases the combined therapy came well up to theoretical expectations.

The following cases illustrate our technique and results:

Case 1.—An African male aged 25. Admitted June 11, 1943.—Flexner dysentery of one-day duration. Stool greenish, watery, with lumps of blood-stained mucus; vomiting, tenesmus marked. On June 12 sodium sulphapyridine solution 1 g. given intravenously and 1 g. every hour orally. Next day motions were brown and semi-formed, and thereafter no motion occurred for 3 days.

Case 2.—An African male aged 5 months. Weight 7 lb. 3 oz. Admitted May 14, 1943, for vomiting and diarrhoea of one week's duration. Breast-feeding (test feeds showed only 2 oz.). Red tongue, emaciated, oedema of feet, and desquamation. Given astringent mixture and supplementary feeds. On May 17 stools still frequent, green, and slimy. Eyes sunken and staring; blinking absent. Sodium sulphapyridine 0.3 g. intramuscularly and sulphathiazole 0.5 g. every hour orally. On May 19 the stool was greenish and formed; eyelids blinked completely, but the child was drowsy—a condition which only too often precedes death in such cases. Two 2-cm. ampoules of exotrope were injected, after which improvement was rapid.

African Hospital, Lagos.

WILLIAM HUGHES, M.D., M.R.C.P.

## Reviews

### HISTORY OF SCIENCE

*A Shorter History of Science*. By Sir William Cecil Dampier, Sc.D., F.R.S. (Pp. 159, illustrated, 7s. 6d.) Cambridge: The University Press, 1944.

Sir William Dampier's *History of Science and its Relations with Philosophy and Religion* when first published in 1929 met with such immediate success that a second edition was called for in the following year. In 1942 he undertook the laborious task of bringing the work up to date. Then he was asked for a straightforward story of the growth of science reduced to its simplest terms, and has written this *Shorter History*. We must confess that on seeing a book of 189 pages we feared it could only present a catalogue of names and discoveries. But those fears proved groundless, and his two expressed aims have been successfully achieved. The first was to show how science, which now affects our lives so profoundly, reached its present predominance, the second was to place science in its appropriate relationship with other methods of thought. It is the story of man's attempts to understand the mysterious world in which he finds himself. He reminds us that "science did not germinate and grow on a healthy prairie of ignorance but in a noisome jungle of magic and superstition, which again and again choked the seedlings of knowledge," while placing it to the credit of Scholasticism that it prepared men's minds by teaching that the world was understandable.

Though we miss some of the engaging philosophical comments of the larger book, there are some pointed sayings, of which a few samples must suffice. "The aether, if there be an aether, is now crowded with 'wireless waves'—a consequence of Maxwell's equation—and however they are conveyed, it is certain 'not on the air'" (p. 104). "In the absorption spectrum of chlorophyll the maximum absorption coincides with the maximum energy of the solar spectrum, a remarkable adaptation, however produced, of means to ends" (p. 118). "It is impossible to predict the velocity of a particular molecule or the length of life of an individual man, but with a sufficient number of molecules or men we can deal with them statistically and say how many will move within certain velocities or how many will die within a given year. Statistical determination, but individual uncertainty" (p. 96). "To the behaviourist a man is only a nexus of stimuli and responses, because the method of investigation, by its own definitions and axioms, is merely the study of the relations between stimuli and responses" (p. 137). "Ritual is prior to and dominant over any definite belief. Compare this with some forms of modern psychology, which say, 'I react to outer stimuli, and so I come to think'" (p. 141). Sir William Dampier gives undeserved commendation to Capt. Cook for his researches on antiscorbutic remedies, whereas in fact Cook did nothing to help and a good deal to hinder the work of his ship surgeon in that direction.

The section on modern physics and astronomy is stiffer reading, and the ordinary reader may feel a sense of frustration at the admitted inability of the physicist to express his conception of matter in anything but mathematical equations. We are left with the discouraging conclusion that "a fundamental principle of uncertainty seems to lie at the base of our model of Nature," a change induced from the confident materialism of the last century, and due to the science which then seemed the most material—physics. But a healthy change, nevertheless.

A book worth meditating over, for it is the outcome of a well-stored and critical mind, with a capacity for distinguishing the essential from the incidental.

### MAN'S ESSENTIAL DILEMMA

*Conscience and Society: A Study of the Psychological Prerequisites of Law and Order*. By Ranyard West, M.D., D.Phil. (Pp. 260, 15s.) London: Methuen and Co., 1943.

This book begins and continues as a philosophical discussion and ends as something like a tract. The sequel is unusual and does at any rate as much credit to the author's heart as to his head. His principal thesis is that mankind's essential dilemma is between mutual co-operation and mutual strife, which he relates respectively to an instinctive tendency to co-operation on the one hand and to aggressiveness on the

other. His principal postulate, which he claims to deduce from general observation, is that the former tendency is uppermost and that aggressiveness is strong only in the neurotic, who, in Dr. West's conception, is by definition an individual suffering from the after-effects of disturbance of his emotional life after childhood. He starts with the hint, not subsequently so fully developed as such a fascinating task would make us wish, that the system of any philosopher is extremely dependent upon his personality and temperament, and in turn therefore upon complexes and the like which have arisen on the basis of his early experience. Hobbes, Loeke, and Rousseau are quoted as illustrative examples. Freud's philosophical excursions, based on his clinical experience, are held by the author to depend to a large extent on Freud's own difficulties with his own instinctive impulses. These speculations are reinforced by reference to clinical cases treated by the author.

The method of proceeding from philosophy to philosopher and thence to a philosopher who has betrayed his own inner processes to some extent in his psycho-therapeutic work (Freud), and finally to clinical cases is ingenious, but it leads to the narrow type of conclusion to which psychologists and psychiatrists are apparently fated. In this instance the conclusion is reached that it is predominantly the obsessional neurotics who are responsible for the woes of nations. Dr. West finds in short that wars depend essentially upon the failure of certain individuals to come to reasonable terms with their own individual conflicts. This is not a novel conclusion, but the author has reached it through a novel line of approach.

Though he quotes, a writer like Horney he does not seem to believe that the structure of the larger society has any particular responsibility in accentuating aggressive urges. Law in general is seen as a means of expressing the social or co-operative instinct and controlling the aggressive tendencies, but when he comes to the practical solution of the problem of war Dr. West does not help us much. The key to international co-operation is seen as the transfer of loyalty, power, and law from the sovereign States to a world community. From this he passes to an argument that would make all belligerents at the present time seem equally guilty. He even says, on page 238, "Ten years after this present war has ceased it will no more matter who 'caused' or who 'won' it than it did ten years after the last one"; and the book ends with something that reads curiously: "Make the great venture! agree with thine adversary—quickly! And place the consciences of the world behind its Total Society." Taken all in all, his conclusions are rather far away from his premisses. The author seems to be no more immune from unconscious personal bias than the generality of philosophers or indeed of mankind.

### WAR SURGERY

*Surgery of Modern Warfare*. Edited by Hamilton Bailey, F.R.C.S. Sub-editor for Medicine, C. Allan Birch, M.D. Compiled by 77 contributors. Part III, third edition (complete in six parts). (Pp. 178; illustrated. 15s., plus 6d. postage) Edinburgh: E. and S. Livingstone. 1944

Part III of the third edition of *Surgery of Modern Warfare* contains articles on the surgery of blood vessels, haemorrhage and its treatment, Thomas's splint and extension, plaster technique, and Braun's and Cramer wire splints. Perhaps the most outstanding contribution, however, is that on amputations by the late Sir William De Courcy Wheeler. This chapter was completed not long before he died, and many will no doubt agree that it ranks high among his contributions to surgical literature. Founded upon a wealth of experience, the sum of a life's work devoted to surgery, it is a masterly exposition from which all young surgeons may learn much. An editorial note at the end of this article tells us that Sir William had, from the beginning of the war, served as a consulting surgeon to the Royal Navy, and died in harness on Sept. 11, 1943. This chapter is "typical of his work and a fitting tribute to a great man."

Like the preceding volumes, this member of the series constituting the third edition maintains the high standard which we commended in our notice of the first parts of the third edition. The subjects included are written by well-known authorities in a clear and essentially practical manner, and are lavishly illustrated both by line and coloured drawings and by photographs.

### Notes on Books

*The Common Form of Niacin Amide Deficiency Disease: Aniacinamidosis*, by Dr. W. KAUFMAN, is published at Bridgeport, Connecticut, by the Yale University Press. This is an entirely uncritical monograph on a syndrome stated to have been discovered by the author and to be due to a deficiency of niacin amide—i.e., nicotinic acid amide or nicotinamide. He calls it aniacinamidosis. The symptoms run almost the whole gamut of those seen in general practice, from corns and fallen arches to grey hair and insomnia. Such varied symptoms as arthritis, impaired memory, lack of initiative, mental and physical fatigue, lack of appetite, foul breath, warts, dyspnoea, and ecchymoses are laid at the door of aniacinamidosis. So numerous are the manifestations listed that every hospital and private patient might be diagnosed as suffering from the condition. The reviewer finds it impossible to take this book seriously. Thus the author states that in five minutes nicotinic acid amide begins to relieve mental symptoms, improves apical heart sounds in fifteen minutes, and makes flabby muscles firm in half an hour. Such uncritical statements are found on opening any page of the book at random.

The official *Medical Register* for 1944 has been published on behalf of the General Medical Council by Constable and Co. (Orange Street, W.C.2) at 21s., post free 22s. The table printed in the introductory section shows that 3,532 names were added last year. New registrations numbered 1,501 in England, 611 in Scotland, 405 in Ireland, 153 on the colonial register, and 862 on the foreign register. The total number of names on the *Register* at the end of last year was 71,882, being 2,454 more than on Dec. 31, 1942. The total number at the end of 1933 was 56,741.

### Preparations and Appliances

#### A PLASTER OVER-BOOT

Surg. Cmdr. P. B. MORONEY, R.N.V.R., writes:

The protection out of doors of a walking plaster is essential. For use with such plasters, incorporating a sorbo or rubber heel, the following boot has been successfully issued from a narrow range of stock sizes. It may be rapidly extemporized in canvas and wood, although leather is more elegant and durable. It consists essentially of a simple leather sole-piece with a 1/8-in. heel cut to tracings of plasters corresponding to sizes 6, 8,

FIG. 1

FIG. 2

and 10 normal shoe fitting. Straps are sewn to it as illustrated in Fig. 1. They are designed to give close fitting posteriorly between the heel of the boot and of the plaster. The upper merely provides protection against weather and should be made capacious. It leaves from 1 in. of the toes, which need not necessarily be blocked; a counter in the heel is the only other refinement.

The correct attachment of the straps, which firmly brace the sole of the boot to the cast, is the essential; for then slight excess of length and breadth does not prejudice gait and permits a free action of the toes. The latter may be protected with a wollen toe-cap specially made or extemporized by cutting the end of a sock.

The boot applied is illustrated in Fig. 2. It may be noted that it is equally applicable to right or left foot.

## CONTROL OF GAS GANGRENE

Gas gangrene, with an incidence of 3 to 10 per 1,000 wounded and a case fatality of 30 to 70%, is still one of the uncontrolled infections of war. Its greatest prevalence and mortality occur at the beginning of any campaign, which aptly illustrates the old tag that only experience teaches. However, the tale twice or many times told may, like the dripping of water on the stone, make its impression in time, and we therefore offer no excuse for reiterating the general principles which should guide the surgeon in the prevention and management of this dreaded infection. With an incubation period measured in hours rather than days, the control of gas gangrene lies principally in the hands of the surgeon at the forward surgical centre. He must learn quickly to know the kind of wound which is most susceptible to clostridial infection—the extensively lacerated muscle injury, particularly of buttock and thigh; the wound contaminated with soil, clothing, or other foreign body; the compound fracture or other injury with its blood supply cut off—and he must realize that a delay of more than 24 hours in attending to any such wound increases enormously the risk of gas gangrene. Thus, American observers<sup>1</sup> found that among some 4,000 wounded soldiers sent to an evacuation hospital 5% developed gas gangrene, and, of these, 90% had symptoms of the infection before reaching the hospital, the average length of time between injury and operation being 41.8 hours. By contrast there was no case of gas gangrene among 349 severe non-transportable cases operated on within 24 hours of injury. The forward surgeon's main concern, therefore, must be prophylaxis, and the principal lesson which the Mediterranean campaigns have driven home is that bold and radical surgery is still the first and best line of attack. The high fatality rates in Sicilian and early Italian battles noted by MacLennan and Macfarlane on another page in this issue were probably attributable more to inadequate surgery by inexperienced men than to any other single factor, and a high duty rests on senior surgeons to see that the front-line surgery is in capable hands.

Where thorough débridement is not possible at the advanced unit, as may happen during the height of battle, free incision to open dead spaces and relieve tension will accomplish much, particularly if, at the same time, the patient is given the benefit of prophylactic antitoxin and antiseptic. Polyvalent gas-gangrene antitoxin had an inauspicious send-off in the early days of this war, and was perhaps unduly overshadowed by the high hopes entertained for the use of sulphonamides in both prophylaxis and treatment. Even now the prophylactic value of antitoxin is hard to assess, and, as the present report shows, it may by itself fail to prevent gas gangrene; but even

when given as late as 24 hours after wounding it delays onset (average incubation period of those receiving prophylactic antitoxin was double that of those without it), and so allows more time for effective surgery. The present prophylactic dose contains 9,000 units of *Clostridium welchii* antitoxin, 4,500 units of *Cl. septicum* antitoxin, and 9,000 units of *Cl. oedematiens* antitoxin, and should be given intravenously wherever possible. That antitoxin given before there is any evidence of clinical infection should fail to protect may be a disappointment to the experimentalist, but it must be remembered that antitoxin *per se* will not prevent multiplication of the organism in necrotic tissue, and the prophylactic dose, adequate as it may seem, will in time be neutralized by the rapidly manufactured toxin. It is here that chemoprophylaxis should play its part by preventing bacterial growth, and now that more effective substances, such as the sulphathiazole-proflavine<sup>2</sup> mixture, are becoming available, much may be expected from the combined use of antitoxin and drug, both in prophylaxis and in treatment. It is to be hoped that controlled field trials of these various prophylactics may be possible in the approaching battles.

The surgeon's second responsibility is to recognize the early signs and symptoms of gas gangrene: the feeling of weight and the increasing pain in the wound area due to oedema and swelling; the rising pulse rate; the change in the patient's mental attitude; tenderness round the wound, with a thin watery discharge, later becoming profuse and sero-sanguineous. Gas at this stage is often absent, and, as MacLennan<sup>3</sup> has pointed out, where there is much gas formation without other evidence of muscle infection the condition is almost certainly not gas gangrene. The peculiar sweetish odour regarded by some surgeons as pathognomonic of gas gangrene may be absent, particularly in oedematiens infection, while discoloration of the skin is rarely present in the early stages. These symptoms may be considerably masked by a persistent "shocked" condition, which must be treated urgently with blood or plasma transfusions and is no bar to surgical intervention. The surgeon will soon learn to recognize the typical muscle changes at operation—at first oedema and pallor, later loss of contractility, absence of bleeding from the cut surface, and a brick-red colour with gas bubbles between the muscle fibres—and he may with more experience be able to differentiate infections due to the different anaerobes (see MacLennan<sup>3</sup>). With infection established, excision of the infected muscles becomes an urgent matter, and the young surgeon will find useful advice on the technique of surgical excision and the treatment of gas gangrene in the revised M.R.C. War Memorandum No. 2. But good surgery is not good enough if it is done too late or without the help of antitoxin, for, as MacLennan and Macfarlane show, surgical excision later than 6 hours after clinical onset, along with inadequate antitoxin, doubles the case fatality compared with early surgery and adequate serotherapy. The immunologist is inclined to be pessimistic about antitoxin therapy, because toxins once formed quickly become attached to susceptible and usually vital tissue, but there is now good evidence that

<sup>1</sup> McIntosh, J., et al., *Lancet*, 1944, i, 591.<sup>2</sup> *Lancet*, 1943, ii, 63, 94, 123.<sup>3</sup> *U.S. Hist. of the World War, Med. Dept., U.S. Army, Wash., 1929, 12, 413.*

intensive serotherapy is of real value in reducing the mortality of established gas gangrene. The *minimum* therapeutic dose is 3 ampoules of the polyvalent antitoxin given as early as possible (that is, before operation) in concentrated bulk intravenously, and repeated every 4-6 hours if there are signs of persistent toxæmia. Nothing else, not even penicillin, can take the place of antitoxin at this stage, though antitoxin along with penicillin or other chemotherapeutic drug is likely to be better than antitoxin alone. The synergistic action of antitoxin and antibacterial agent has been well established experimentally, but in dealing with the clinical infection the surgeon should regard them as medical aids to radical excision of the affected tissue. The hope expressed early in the war that drugs like the sulphonamides would allow of more conservative surgery has not yet been realized.

### THE MECHANISM OF INFLAMMATION

Many readers will already be familiar with the work of Menkin of Harvard, who has been engaged for the past fifteen years in re-studying the process of inflammation *ab initio*. The phenomena of inflammation have been well recognized and described in much the same terms since the days of Cohnheim and Metchnikoff. Menkin was ill content with a mere description of what happens, and has sought reasons for it. In claiming to have found these he has introduced four new concepts, two of which take concrete form in substances liberated in areas of inflammation and having specific effects. These are leukotaxine, a polypeptide which has been isolated in crystalline form from inflammatory exudates, and is responsible for increased capillary permeability and a chemotactic effect on leucocytes, and the leucocytosis-promoting factor, a pseudoglobulin which acts on the bone marrow. His other new concepts are the effects of pH in regulating cytology, and the fibrin barrier, which walls off the affected area and constitutes "the primary and basic mechanism of fixation" or localization of the process. It is implicit in Menkin's general hypothesis that inflammation is essentially the same, however produced. He writes of a "basic pattern of injury" and a "fundamentally stereopatterned reaction" caused not only by any kind of microbic invasion but even by physical and chemical agencies. He has in fact freely used heat and turpentine to produce the exudates with which some of these studies were made.

To all this Menkin<sup>1</sup> now adds another mechanism, which he claims to have demonstrated, in the form of a third specific substance which is responsible for local injury and for fever and other more distant effects. This injury factor, which he calls "necrosin," is contained in the euglobulin fraction of inflammatory exudates, from which it can be extracted by prolonged dialysis. This substance, obtained from the effusion in a dog's pleural cavity caused by an injection of turpentine, produces oedema, hyperæmia, and even some necrosis when injected into the skin of a rabbit, and the retention of trypan blue in the affected area shows that the lymphatic blockade characteristic of an inflammatory reaction has been set up. The dog pleural

exudate itself has the same effect, showing that the substance is not formed artificially by chemical manipulation, and the pseudoglobulin and albumin of the exudate have no such effect, nor has the euglobulin of normal dog serum. Necrosin has also been obtained from human exudates of unspecified nature, but was not demonstrated in ascitic fluid from a case of cirrhosis of the liver. That the reaction in the rabbit is not merely a foreign-protein effect is shown by the inactivity of dog proteins other than exudate euglobulin, and by the fact that this will cause similar changes in the skin of the dog itself, though these are described as "perhaps not quite as intense." Necrosin can also be extracted from the blood serum of a dog a day after inducing a pleural effusion with turpentine. That it is in fact absorbed from inflamed areas and exerts distant effects is shown by the consequences of injecting it intravenously in normal animals. These are sharp fever, and a leucopenia succeeded by a leucocytosis. Degenerative changes were also found in the liver and kidneys with leucocytic infiltration, and some of the animals died. An attempt is made to relate these effects to that theory of the causation of shock which attributes it to a toxic substance liberated at the site of injury, but, as the author himself points out, the fact that necrosin does not lower the blood pressure is difficult to reconcile with this idea.

Many pathologists will feel that they would prefer to repeat these experiments themselves before being called upon to comment on the very important conclusions to which they have led. What is involved here is a proffered explanation not only of local damage in inflamed areas but of fever itself and presumably of the degenerative visceral changes seen in acute infections. Purely speculative criticism can be offered only in a tentative way, but there are difficulties which present themselves at once. Menkin himself acknowledges that during dialysis changes may occur in serum proteins, a fact demonstrated by Chick thirty years ago, and, in spite of an experiment which appears to prove the contrary, some suspicion remains that the process of extraction of necrosin may have produced something which was not in the original material. Another difficulty is this: one can accept as reasonable the idea that the body proteins should furnish substances causing increased capillary permeability, chemotaxis, and stimulation of the bone marrow, since these are necessary and beneficent reactions, but why should the body itself manufacture the substance which does all the damage, both local and general? In other words, leukotaxine and the leucocytosis-promoting factor are teleologically credible, but necrosin is not. Finally—and here we are on more factual ground—where in this hypothesis is there a place for bacterial toxins? If we are to regard all inflammation as essentially the same, the suggestion that local damage, fever, and visceral degenerations are due to a euglobulin formed at the site of infection must presumably apply to pneumonia, typhoid fever, diphtheria, and a score of other acute infections. To take only one example, the local damage in diphtheria, which is a necrosis converting the normal mucosa into the diphtheritic membrane, is unquestionably due to diphtheria toxin, as are the viscera and nervous changes in this disease. Although the pre

<sup>1</sup> Arch. Path., 1943, 38, 269.

dominating part played here by a single toxin is paralleled in few other infections, other bacteria produce a variety of toxins with demonstrable local and general effects. It is to these that the phenomena of microbic inflammation have hitherto been attributed, and the temptation to disregard them in favour of a euglobulin is quite frankly not very strong. That such a substance may be formed and have important effects when normal tissues receive gross physical or chemical insults can more readily be believed, but to distinguish thus between different types of inflammation is to abandon Menkin's cherished hypothesis of its unity.

### SULPHONAMIDE PROPHYLAXIS OF GONORRHOEA

Some time after it had been demonstrated that sulphonamide preparations could cure gonorrhoea it occurred to various workers that these drugs might also be of value in the prophylaxis of the disease, much in the same way as arsenical derivatives or bismuth compounds have been used for the prophylaxis of syphilis. Burke,<sup>1</sup> for instance, recommended acetarsol 0.75 g. daily for three days, while others have shown that prostitutes may be prevented from developing syphilis if a depot of bismuth is maintained in their tissues by means of repeated intramuscular injections of a bismuth compound. These methods represent a systemic in contrast to a local method of prophylaxis; and the same applies to sulphonamide compounds administered by mouth. As prophylactics these may be given *before* exposure, in which case the drug is circulating in the blood stream by the time the gonococci first reach the tissues; or *after* exposure but before signs and symptoms have had time to develop: the latter really represents early treatment, since it is assumed that the germs have already been implanted in the tissues. Joses, and Kline and Ryan<sup>2</sup> have recorded their observations on 1,800 naval ratings in an Asiatic station: in a period of some months only two cases of gonorrhoea developed in men taking the full prescribed doses of sulphathiazole. Joses's method was to administer on the day after exposure 3 g. of sulphathiazole at 8 a.m., 2 g. at noon, and 1 g. at 6 p.m. Kline and Ryan gave 2 g. of sulphathiazole on the morning after exposure, and 2 g. about five hours later. Loveless and Denton<sup>3</sup> used sulphathiazole prophylaxis on a test group of 1,400 negro soldiers with 4,000 others as controls. Their method was to give 2 g. on leaving barracks (i.e., before possible exposure), 2 g. on return, and 2 g. next morning. Admission rates for gonorrhoea fell from 171 to 8 over a period of seven months. Arthur and Dermon<sup>4</sup> gave sulphathiazole to 152 men who had had 199 exposures, and compared these with 259 controls who had had 384 exposures: the latter had 15 infections with clinical gonorrhoea as compared with none in the former. The dosage was 3 g. after breakfast on the day after exposure, 2 g. after dinner, and 1 g. after supper.

There is thus evidence that sulphonamide compounds can prevent the development of gonorrhoea if given in adequate doses and at the right time. On the other hand, as shown by Reynolds, Evans, and Walsh<sup>5</sup> and Reynolds and Shaffer,<sup>6</sup> there is evidence that susceptible individuals may, under the influence of sulphonamide drugs, show deterioration in mental efficiency and hand-and-eye co-ordination. It would therefore seem that there is some risk in giving these drugs for prophylactic purposes,

especially to those whose duties require a high degree of mental and visual efficiency such as airmen, engine drivers, drivers of public service vehicles, etc. Not only this; but cases of serious intolerance have been reported after relatively very small total doses of these drugs, and it is open to question whether such risks should be taken when other methods of prophylaxis are available. Other factors have to be taken into consideration. Are these drugs to be given to those who may possibly take a risk, to those who will probably do so, or only to those who have done so? Even the last would involve a very large expenditure of an expensive drug, while supplies sufficient for all three would be colossal. On the face of it few would recommend routine sulphathiazole prophylaxis *before* a possible exposure; and it is doubtful whether it could be done on any scale in any but very exceptional circumstances when other more generally accepted forms are highly effective if applied in time *after* exposure. Then again, what is going to be the effect if large numbers of persons are more or less regularly dosed with sulphonamides? The regularly promiscuous person might be under *almost continuous sulphonamide medication over considerable periods of time*. How would such a man react if he contracted gonorrhoea, and what would be the risk of creating sulphonamide-resistant strains? All these factors would have to be taken into account before recommending the general prophylactic use of sulphonamides in gonorrhoea. At present it seems that such use should be limited to certain special circumstances. Incidentally, there does seem to be one way out of the difficulty—namely, to use micro-crystalline sulphathiazole locally as a urethral instillation after exposure to infection, and this is said to have been effective.<sup>7</sup> The difficulties in the prophylaxis of gonorrhoea are not so much in the methods to be employed as in getting the exposed person to carry them out thoroughly and conscientiously.

### ESTIMATION OF POPULATION

The probable size of the population of the future has been a subject of interest and speculation from two opposite points of view. The seventeenth century school of political arithmeticians believed that the population would continue to grow and that the country and eventually the world would be overpopulated. At the close of the seventeenth century Gregory King, forecasting the future population of England, predicted that it would be 22 millions by the year 3500 should "the world last so long." His estimate for the year 2000 was 8,280,000, or less than the present-day population of Greater London. These forecasts were based on very scanty data: the actual population of the country in King's time was unknown. Until recent years the general principle of an increasing population was accepted. The estimation of the numbers that could be supported varied with the developments in agriculture, transport, and industry. But to-day we speculate about the possible rate of decrease and the size and date of the maximum population. The slow decline in the birth rate, which began during 1870-80, was compensated for by a decreased mortality during the first years: but the probability of a declining population became almost a certainty with the accelerated fall of the birth rate during the first decades of the present century. Recent publicity given to various demographic prophecies has stirred the still pool of public opinion. "More babies" has become the watchword. It is impossible to forecast the size of the population accurately even only ten years ahead, but a general idea of the future may be obtained by considering various hypotheses.

<sup>4</sup> Ibid., p. 563.

<sup>7</sup> Stedman, H. E., U.S. med. Bull., 1943, 41, 1115.

Glass<sup>1</sup> has collected recent estimates of the future populations of Great Britain and several other countries. All the predictions for Great Britain have been published since 1934. The eight forecasts for England and Wales, by four authors, varied much. The maximum population ranged from 40,214,000 to 43,820,000, and the year of the maximum was placed as early as 1936 and as late as 1960. The actual population has already exceeded four of the predicted maxima. The three forecasts for Scotland dated the decline of the population between 1941 and 1970, with a maximum between 4,970,000 and 5,361,000. Five estimates of the population trend of Great Britain are given: three of these are by the Registrar-General and two by private authors. The latter dated the maximum at 1936 and 1941, and their maxima have already been exceeded by one million. By the Registrar-General's estimates the maximum population will occur between 1941 and 1961 and will be between 47 and 48 millions. The chief reason why some of the forecasts have already proved to be too small is that the birth rate failed to decline in the immediate pre-war years at its previous rate. In fact there was a tendency for the birth rate to rise very slightly between 1935 and 1939. The effect of the war on population growth is at present unknown, but in Europe it has beyond doubt caused a considerable change. At home the first years of war saw a rise in the birth rate and a lowering of the average at marriage. These factors tend to postpone a decline in the population.

### DRUG CONTROL IN LIBERATED EUROPE

The probability that illicit traffic in narcotic drugs may find a fruitful soil in the liberated, dislocated, and poor countries of Europe has been exercising the minds of the Permanent Central Opium Board, which has concluded in London its forty-third session. The possible growth of the evil in certain Balkan countries is regarded with concern. The poppy is legitimately cultivated in these regions for its edible seeds, which are used in food manufacture, but the stalk of the plant during the last ten years has been increasingly used for the extraction of morphine. It is feared that in the countries at present occupied—especially those in which the Germans have destroyed the civil service—the control over exports, imports, and manufacture may have broken down, and that the Allied Armies, on entering, may be faced with an extremely difficult task in coping with the drug situation among the suffering peoples. The Board therefore resolved to give as explicit advice as possible on the subject.

At the close of the Board's session Sir Atul Chatterjee, the president, in an account of its proceedings given to members of the Press, said that British, Dutch, Chinese, and Indian representatives had attended, and the conclusions had received the support of the American representative, who had been unable to attend. He pointed out that the Board itself has no power, nor is it equipped, to exercise control directly in any country or area. Its supervision can be exercised only by the examination of statistics and returns sent to it by national controls. It is only the occupying Powers which in the first instance will be in a position to ensure the proper control of dangerous—that is, narcotic—drugs, and so prevent an epidemic of addiction such as occurred immediately after the last war.

Certain general suggestions have therefore been formulated by the Board in the hope that they may be of use to the authorities in establishing control in the areas for the administration of which they are responsible. For the present the Board has confined itself to the period of military control; further stages will be those in which the

national administration with Allied occupation and supervision is re-established, and the initial period of full national control. The Board suggests that on the liberation of an occupied country, in whole or in part, there should be set up, concurrently with the taking over of the civil administration, an authority designated for the purpose by the occupying Forces. This authority would require all stocks of drugs in civilian hands to be notified to it and placed under its control; it would also control all drugs brought into the country for civilian use, and issue licences for the distribution of such drugs through approved relief organizations, wholesale firms, and recognized pharmacies; it would exercise control over factories for the manufacture of drugs and the establishment of any new factory, and would also have under its strict supervision the import or export of drugs or raw materials. It is proposed that the supply of narcotic drugs for civilian use should be solely on the prescription of a qualified medical practitioner, this requirement to be enforced by inspection, by periodical returns of all transactions and supplies by relief organizations and wholesale firms, and by a system of checking of stocks by qualified officials.

Perhaps it should be added that the jurisdiction of the Board extends much further than that of the League of Nations. It is not an organ of the League, and it has the adhesion of countries like the United States, which never was a League member, and of Soviet Russia, which ceased to be. It was set up by the international conventions of 1925 and 1931, which have been ratified probably by more countries than any other international convention except those relating to the Red Cross and the postal service, and, so far as is known, the conventions have not been denounced by any Government in spite of the war.

### BIRMINGHAM UNITED HOSPITAL

The annual report of Birmingham United Hospital expresses with more than usual appreciation the indebtedness of the board to the visiting medical and surgical staff. With their number still further cut down, with only an attenuated resident medical service at their disposal, with obligations to other hospitals as well as to the Ministry of Health, together with the demands of their consultant practices, they have worked under continual pressure, and yet have maintained the services at the hospitals—the General Hospital in the city and the new Queen Elizabeth Hospital at Edgbaston—in a way to evoke admiration. Tribute is likewise paid to the nursing staff. In some comments on the White Paper the report states that it may be assumed from that document that, especially in the case of the larger voluntary hospitals, the whole of the services of such hospitals will not necessarily be requisitioned for the national scheme and that there will remain scope for "private" service. In that event it can fairly be argued that the proposed Government grant per bed, plus the payment towards the cost of treatment and maintenance of patients under the national scheme, should at least reimburse the hospitals fully for this particular part of their service. The number of in-patients treated during 1943 at the Queen Elizabeth Hospital—12,136—is the highest for any year since the hospital was opened in 1938.

At the meeting of the Medical Society of London held on May 8 the Annual Oration on "A Clinical View of Shock" was delivered by Mr. S. Zachary Cope. At the same meeting Mr. W. Sampson Handley was admitted an honorary fellow. The second of his two Lettsomian Lectures on "The Mechanism of Visceral Pain" will be delivered by Prof. Henry Cohen on Wednesday, May 24, at 5 p.m.

## TINEA INFECTIONS OF THE SKIN

• 'Mersagel' is a convenient product with a single clinical purpose, the treatment of the more common mycotic infections, chiefly ringworm of the foot, groin and axillae.

It is effective, soothing and clean to use.

It has also a prophylactic value, which will prove useful with patients who, having contracted ringworm and got rid of it, want to escape reinfection.

**'MYOCRISIN'** booklet

**'MYOCRISIN'**  
TRADE MARK BRAND  
sodium aurothiomalate

MANUFACTURED BY  
**MAY & BAKER LTD**

A new edition of this much requested publication is now available. Following American investigations on the subject, the pharmacological sections have been re-written and reflect the recent trend of opinion concerning the mode of action of gold from stimulation of the reticulo-endothelial system to the original conception of a direct bacteriostatic or bactericidal action. The gold therapy of rheumatoid and other forms of arthritis is described, as is its use in various dermatoses and other conditions. The reactions which may occur during gold therapy are discussed in their aetiological, prophylactic and therapeutic aspects and there are notes on the erythrocyte sedimentation rate. A bibliography of the more important papers on the different aspects of gold therapy is appended.

A copy of the 'Myocrisin' booklet is free on request for members of the medical profession.

## DEHYDROCHOLIN B.D.H.

Dehydrocholin B.D.H. is an efficient cholagogue and choleretic issued for use by injection in the form of a solution containing 20 per cent. of sodium dehydrocholate in ampoules of 10 c.c. and for oral administration in tablets each containing 0.25 gm. of dehydrocholic acid.

The indications for Dehydrocholin B.D.H. are all those states which are attributable to biliary insufficiency, with the exception of jaundice in which there is evidence of complete obstruction of the bile duct. Specific conditions in which Dehydrocholin B.D.H. should be administered include catarrhal and latent jaundice, hepatic congestion and cirrhosis, cholelithiasis, cholecystitis, hepatitis and acute alcoholism. In this last condition, it is an advantage to administer Vitamin B<sub>1</sub> B.D.H. collaterally. Dehydrocholin B.D.H. also possesses the power to increase the diuretic effect and to decrease the toxic effects of mersalyl.

Dehydrocholin B.D.H. is normally administered parenterally, but the effect of an injection may be prolonged by giving tablets of Dehydrocholin B.D.H. orally, a procedure which may be employed as a means of lengthening the intervals between injections.

*Details of dosage and other relevant information will be gladly supplied on request.*

## PLANNING FOR BASIC RESEARCH IN OPHTHALMOLOGY

BY

C. G. KAY SHARP, M.D.

There is a distinction between planning for research and planning of research. The former is largely carried out by the Government, local authorities, philanthropists, and other public-spirited members of society, be they professional or lay members. The latter is mainly the affair of university administrators and researchers.

There is nothing new in planning for research. The Privy Council planned for research when it appointed the Medical Research Council and when Parliament voted funds for that purpose. That this legislative foresight has been amply justified by results and by progress is beyond doubt. The nation has an enormous burden of, sickness and mental and physical disability, and the Medical Research Council has the stupendous task of attempting to reduce this burden. It is highly improbable that sufficient funds have so far been available to perform this task on a scale commensurate with the enormity of the burden, but much has been done, and successfully done. To say that all aspects of physical disability have been satisfactorily covered by the work to date, supervised by the Medical Research Council, would be to invite criticism. In particular, the great burden of blindness and ophthalmic morbidity, with its financial, commercial, and humanitarian implications, has during the last generation received less generous attention than its importance merits. Surgical technique has been improved, ophthalmology has benefited by drugs and other remedies which are the result of much research outside ophthalmology, but the same great causes of blindness are with us to-day as they have always been, and insufficient organized effort, under optimum conditions, has been made to prevent these causes or remedy their effects.

Local authorities in England are charged with the financial burden of the care of the blind, and they have discharged that duty magnificently. They are consequently interested in prevention of blindness. They have for some years considered alternative methods, designed to secure the maximum success in its prevention. This subject has been viewed from many angles, and I have been successful in directing the attention of these administrative bodies towards research in ophthalmology, carried out under optimum conditions, as being the basis on which all efforts in preventing blindness should be built.

### Team-work and Planning

Research in ophthalmology indicates team-work. It is by no means confined to the activities of ophthalmologists, and it is highly probable that the basic sciences—physiology, biochemistry, and biophysics—will play a part in the prevention of blindness greater in importance than applied ophthalmology; and much research work which is carried out in subjects not directly related to ophthalmology will quite possibly have an important bearing on the causes of blindness—e.g., W. T. Astbury's work on textile fibres (University of Leeds).

From these considerations two needs will be evident: that money must be provided, and that research in ophthalmology must be carried out in close association with the basic sciences, other research units, and clinical facilities.

Local authorities have decided that they are willing to provide the necessary funds for development in research in ophthalmology, carried out under the best possible conditions. It is here that planning is essential. A minimum amount which should be voted for the provision of this research must be estimated. The contribution of each local authority must be assessed on a basis of population. Frequent requests to local authorities for small amounts must be avoided. Many other considerations need to be made, all of which require careful planning.

Dr. F. M. R. Walshe has stated in reference to research personnel: "No planning can provide us with these men or determine the goal of their labours"; and again, "It is round the man and not round the plan that the wheels of research revolve most rapidly." These views have the concurrence of

Sir John Parsons, the Galen of ophthalmological research. The principles involved have already been adopted in the two recently established Ophthalmological Research Centres—(1) in the University of Oxford (Ida Mann); (2) at the Royal College of Surgeons and Royal Eye Hospital (Arnold Sorsby)—except that in the case of Oxford the wheels of research are revolving round the woman.

There is little doubt that a similar course would be pursued by the universities which are at present preparing their schemes if equally acknowledged researchers should become evident. If there are no candidates of the required standard of merit available or likely to be available, how much this unfortunate state of affairs is due to the lack of financial planning in the past is possibly debatable, but it is interesting to speculate how many probably distinguished researchers have been lost to research on account of the more attractive rewards in other branches of the practice of medicine.

To state that none of our most eminent surgeons or physicians, had they devoted their lives to fundamental research, would not have reached equal eminence, would indeed be rash. It would seem, therefore, that an attempt to find suitable leaders of research of proved ability should be made, and, if unsuccessful, then appropriate financial arrangements should be planned (as they have already been planned, as a minimum, in regard to five centres), providing for the recruitment and training of workers.

The rewards of research, as the most valuable branch of medicine, should be assured and ample, and efforts should be made to direct the attention of suitable junior graduates to that vastly interesting and fascinating vocation. That all selected trainees would become ideal researchers is improbable, and for this reason—if for no other, so far as medical graduates are concerned—clinical work should be combined with research work.

One has only to read the biography of Sauter in order to realize that, although a man's ambitions and interests may at one period of his life be concentrated on a certain type of occupation, his interests may be diverted and be productive in an entirely different pursuit. Sauter's greatest ambition was to become an engineer; he was apprenticed to a chemist much against his will, and it was due to the ingenuity of his principal, who deliberately and secretly broke his chemical apparatus in order that the engineering ability of his apprentice could be exercised, that the apprentice's attention was eventually diverted to chemistry. Gradually Sauter found chemistry to be of greater interest than engineering, and eventually gave to the world—morphine.

### Choice of Research Workers

An unfortunate idea seems to have developed that ophthalmological research should normally be the sphere of action of an ophthalmic surgeon. While a certain knowledge of applied ophthalmology is useful, there is ample reason to believe that it is to the university laboratories rather than to the out-patient room to which we must look for any real addition to our basic knowledge of the causes of blindness. The provision of a larger number of selected junior researchers specially concerned with the biophysics, biochemistry, and physiology of the eyes seems to be indicated as the most promising approach to prevention of blindness, and it is now certain that financial assistance will be forthcoming in support of this. By this method the choice of the man or woman around whom the "wheels of research will revolve" will be much wider, and he or she will have had the advantage of appropriate basic training—so necessary in modern research. When one considers the haphazard methods, empirical in the extreme, by which researchers in bygone days carried out their investigations, it is amazing that anything was ever discovered.

There was no planning for research in the days of Antonj Leeuwenhoek. His university was the draper's shop. He was despised by the punctis of his day because he could not write his observations in Latin. One cannot imagine the present-day scientist getting his training for experiment among bolts of gingham, listening to the tinkle of the bell of the cash drawer, and being polite to an eternal succession of Dutch housewives; but that was Leeuwenhoek's apprenticeship, and

later he had his own draper's shop. By day he sold gewgaws; by night he melted the metallic ore to make his rudimentary microscope and ground his wonderful lenses by which he could see things never dreamt of by his forebears. We have advanced a little since Leeuwenhoek's days, but even now the descendants of Leeuwenhoek's critics exist. Encouragement, organization, and financial provision are slowly but surely taking the place of professional jealousy and *laissez-faire*.

The recent decision by the County Councils Association and the Association of Municipal Corporations to provide a minimum sum of approximately £20,000 per annum for ophthalmological research, with a definite bias towards prevention of blindness, is an epoch-making measure in ophthalmology, and furnishes universities and Royal Colleges with sufficient immediate financial assistance for considerable reorganization of research personnel, trained and to be trained.

It may be possible to secure the release from the Services of any outstanding researchers with the necessary experience if they are not employed on war work of vital importance; the flow of suitable candidates for junior posts and for training may be slow until the end of the war, but in the interim the decision of the Local Authorities Associations will enable selected centres to begin work on ophthalmological research and to draft and plan for extension as personnel becomes available.

## THE PUBLIC HEALTH SERVICES

### ADDRESS BY MINISTER OF HEALTH

The Minister of Health was the principal guest at the annual luncheon of the Society of Medical Officers of Health. In proposing the toast to the Minister, Dr. R. H. JOLLY, president of the society, said that members of the public health service as a rule did not air their grievances or their anxieties in the medical or lay press, but some of them, particularly those in maternity and child welfare work and school medical work, were wondering what place would be found in the new health service for the preventive and educational structure which had been so well built up by them during the last twenty-five years. They were conscious of a vague shape ahead—not, indeed, a black cloud, but a White Paper.

Mr. WILLINK began by paying a tribute to the public health services, the general result of whose work was greatly to the credit of those engaged in it. He said that the provisional rates showed a fall in maternal mortality from 2.47 per 1,000 births in 1942 to 2.29 in 1943. The crude rate of infant mortality had fallen from 49 to 48, and the final corrected figure for 1943 was likely, for the first time in the records, to be below 50. In the first quarter of 1941 the number of deaths from diphtheria was 841; it fell in the corresponding quarters of 1942 and 1943 to 627 and 498 respectively, and for the first quarter of this year to 285. It was evident that these figures were closely related to the campaign for diphtheria immunization, the fall having chiefly occurred in the age group 1-15. On the other hand the provisional crude death rate from respiratory tuberculosis in 1943 was higher than in 1942, being 557 per million of the population as compared with 506, an increase related no doubt to the influenza epidemic, which reached its peak in December, 1943. But in 1918, the corresponding year of the last war, the figure was 1,322. The incidence of venereal diseases had also increased, although it was not so high as in the last war.

### The Government's Proposals

Turning to the Government's proposals for a National Health Service, the Minister said that he had invited discussion and criticism, and the invitation had been accepted. These proposals were not going to be put into legislative form in a hurry, and the Society of Medical Officers of Health was exactly the sort of body from which he hoped to receive constructive criticism. He had heard comments made that in this field, as in that of nursing, the references to the public health services were meagre. But he felt that he could point to first-class evidence of the importance attached by the Ministry to the work for which M.O.s.H. were responsible. It was a great

satisfaction to him to have obtained the services as additional Deputy Chief Medical Officer of Dr. J. A. Charles, M.O.H. for Newcastle. He hoped it would be possible, notwithstanding Dr. Charles's acceptance of that appointment, for him to maintain his close connexion with the society. Here also Mr. Willink congratulated the president-elect of the society (Prof. R. M. F. Picken), who was a member of his Medical Advisory Committee.

"Taking the general nature of the proposals," Mr. Willink continued, "I cannot help thinking that many of the proposals which the society itself has made are to be found in the White Paper—universality of service, treatment available without charge at the time of treatment, larger areas especially for hospital services, full use of voluntary hospitals within the service, establishment of Health Centres, closer contact between preventive and curative medicine, central and local professional consultative bodies, and a new outlook and emphasis on social medicine. All these matters are common to your proposals and those of the Government. The differences are really in method and not in principle and intention."

### Three Main Differences

There were three main differences between the society's proposals and those of the White Paper. The society had suggested one central department to absorb all governmental health functions and to be concerned with health and nothing but health. That issue was faced in the White Paper, but it was felt that there were Government Departments which needed medical advice if they were to fulfil their functions, although health was not their main function. Any peril of cleavage could more appropriately be met by close liaison and community of staff. Then the society had suggested—as the National Association of Local Government Officers had also done—that a one-purpose authority should be created in each area, not a Joint Authority as the Government proposed. This question had been dealt with in the third appendix of the White Paper.

"The society will realize that their proposals mean a complete recasting of our whole local government system. That would be a large and prolonged undertaking, and we do not feel that the new health service can await the end of so long a process. But I should like to say that the Joint Authorities which we contemplate will require, in view of the functions we suggest for them, a medical staff of the highest status, with work to do which I imagine will be of immense interest and responsibility. We feel that the planning of the health services in these areas in consultation with the constituent local authorities and with professional and with voluntary hospital experts will be a business calling for high gifts, and that we shall get very great assistance from members of your society."

The third and most controversial of the proposals was that a whole-time salaried service should be instituted for all branches of medical practice. "Of all subjects that is the one on which I should be least wise to embark on this occasion. It is sufficient to say that I feel pretty sure that you realize that you are making a proposal of very wide scope!"

Mr. Willink said that he appreciated the natural anxiety which some of them must feel as to the future of the service. If it was felt that there was likely to be any loss of efficiency, let the Ministry be told and consulted. As against this, he knew they would set on the other side the new statutory duty of securing a full hospital and consultant service, the new responsibilities in relation to home nursing and to Health Centres, possibly also in relation to dental and ophthalmic services. In all these ways there must be immense additions to the scale and importance of the work of medical officers of health.

In a number of fields he got the impression that medical officers—and general practitioners also—under present arrangements had more purely administrative work than was desirable. That was something to be watched in the new arrangements. The importance of educating the public in health matters was something to which he hoped they would pay attention. He had learned a great deal of the work of the Central Council for Health Education, he had seen something of the work of health visitors.

"In all these fields and in the field of what is to-day described as social medicine and positive health you have a great and increasing part to play. I hope that you will deal with all these matters, provided for only in outline in the White Paper. We have in mind to a very full extent, in spite of the brevity of the reference to medical officers of health in the White Paper, the contribution which they are going to make."

## Correspondence

### Aerial Convection from Smallpox Hospitals

SIR.—The article by Dr. Killick Millard (May 6, p. 628) is a useful reminder of a problem which has not yet been solved. More recent events than those he recounts cause one to suspect that smallpox may possibly be transmitted at long range through the air. The question was dealt with by Sir A. S. M. Macgregor in connexion with the 1920-1 epidemic in Glasgow,<sup>1</sup> with the conclusion that, while there was some ground for suspicion that a hospital had disseminated smallpox in its vicinity, the evidence was not definitive. According to my recollection (admittedly not too reliable after twenty-four years), when cases began to be admitted to a different hospital the disease began to occur in its vicinity, but here again it was impossible at a late stage of the epidemic to exclude other possible sources. More definitely, and in this case I can speak from personal knowledge, a confluent case was admitted to the smallpox compound of a hospital from a distant part of the city at a time when no other cases were occurring, and this was the only case of smallpox in that hospital. Death occurred within a day or two. After the lapse of the usual incubation period, patients in a scarlet-fever ward, who had been there too long to have been infected with smallpox before admission, sickened of the disease. The wards in question were among those overlooking the smallpox compound. Of course, it was not possible to exclude carriage by members of the medical staff, who were naturally keen to see this then unusual disease, but they were accustomed to take reasonable precautions, and the juxtaposition of the wards in question seemed to be significant.

Much more striking were the events at Gravesend in 1938, when disembarkation of a case of smallpox of foreign origin was followed by six non-contact cases, four of whom lived at distances ranging from a quarter of a mile to one and three-quarters of a mile from a hospital containing at least one case in the acute stage.<sup>2,3</sup> Apparently no other source of infection was traced in these instances, but other circumstances of this little outbreak indicate that the infection may have been of an unusually dispersive type.—I am, etc.,

Welsh National School of Medicine, Cardiff.

RALPH M. F. PICKEN.

SIR.—Dr. Killick Millard believes that the case for aerial convection of the virus of smallpox is "very strong"; but he cannot have it both ways. If the virus may be aërially transmitted in effective dosage over distances of the order of half a mile, how can he—a staunch opponent, moreover, of compulsory vaccination—seriously suggest the reception of patients suffering from variola major by "general isolation hospitals" in which the approved distance between ward blocks is 40 feet?—I am, etc.,

E. H. R. HARRIES.

London, N.15.

SIR.—An incident that happened at Salonika in 1917 bears out the air-convection theory so well described by Dr. Killick Millard (May 6, p. 628). A seaman was admitted to a general hospital in the town of Salonika and was subsequently diagnosed as smallpox. He was isolated in a tented camp half a mile from any habitation except the tents of the isolation hospital to which his camp was attached. Yet there was an outbreak of smallpox among the personnel of an ordnance depot which was just half a mile away across a sandy desert. Over twenty cases (British and Greek) were admitted, and there were several deaths among the unprotected. There were no cases in the general hospital where the original case had been admitted.—I am, etc.,

P. G. EASTON.  
Lieut.-Col., R.A.M.C. (ret.).

Sutton Green, nr. Guildford.

### Penicillin for Skin Diseases

SIR.—We have studied carefully and with considerable interest the report on the therapeutic properties of penicillin, with special reference to the section on the treatment of skin diseases (Roxburgh, Christie, and Roxburgh, *B.M.J.*, April 15, p. 524). We note that certain cases were treated with an aqueous solution of penicillin (1,000 units per c.c.m.) used as a spray. This method of application was adopted by us at the end of January, 1944. It was tried out extensively in the skin department of a large military hospital, and satisfactory results were obtained using a strength of only 200 units per c.c.m. So far as we have ascertained, the spray technique had not previously been used.

We have been experimenting with various applications of penicillin for the treatment of certain skin diseases since September, 1943, and in our opinion the spray technique has given the best results, and in the strength used we have found it the most economical preparation of penicillin. A full report will shortly be published.

We would be interested to hear whether the cases which appeared to be irritated by the penicillin ointment or spray were growing penicillin-insensitive organisms at the time penicillin treatment was stopped. Our own observations suggest that in these cases penicillin-insensitive organisms have appeared, and have been the cause of the condition getting worse. The purity of the petroleum jelly used in the base might also be a factor in the causation of irritation. In the first series of cases treated by us, one particular batch of petroleum jelly caused definite eczematization.—We are, etc.,

P. H. TAYLOR.

K. E. A. HUGHES.

### Status Lymphaticus

SIR.—In reply to Major G. R. Peberdy's inquiry (April 29, p. 600) I can say that in the course of some five years' work in the coroner's districts of South London, East Surrey, and the county borough of Croydon, also in hospital practice as a pathologist in and around the London area since 1929, during which time I have carried out an average of not less than three hundred necropsies a year, I have not seen a single case of status lymphaticus. I personally do not believe in the existence of such an entity. With the volume of sudden deaths that I am called upon to examine I feel sure that had the condition a real existence I should have seen at least one case.—I am, etc.,

London, W.1.

DAVID HALER.

### Nutritional Oedema in a Vegetarian

SIR.—The case of nutritional oedema in a vegetarian reported by Dr. Holmes (May 6, p. 620) is of great interest in view of the reports of the widespread incidence of this condition in occupied Europe. While the findings are highly suggestive that the oedema was produced solely by the hypoproteinaemia, it is not possible from the evidence adduced to exclude the influence of myocardial weakness. It is known that oedema of cardiac origin may occur in the absence of enlargement of the heart. Presumably in this case signs of a general increase of venous blood pressure were absent and the blood circulation rate gave a reading within normal limits; otherwise the effect of improvement in the nutritional state of the myocardium cannot be overlooked. In raising this point I have had in mind that reports indicate that sudden death, presumably of cardiac origin, is a not uncommon means of termination in cases of hunger oedema.—I am, etc.,

Dundee.

D. G. MCINTOSH.

### The Effects of Cold

SIR.—Will you allow me to trespass upon your valuable space to comment upon Mr. Norman Lake's reply (April 22) to Dr. Raymond Greene's letter of April 1. I think it is important to our conception of the pathology of the cryopathies to point out that the lesion is one associated with the tissue as a whole rather than with a collection of cells intertwined with blood vessels. The pathology is thus best considered on a tissue rather than a cellular basis.

Mr. Lake in his reply to our paper on immersion foot (Goldstone and Corbett, Feb. 12) was severely critical of our suggestion for the use of an electric cradle in the early stages. This criticism is clearly justified relative to a state of pure frost-bite. It was just such a plea for a measure of distinction as Mr. Lake cites in the final paragraph of his letter (April 22) that we wished to make. The clinical picture in immersion foot, apart from the oedema, is akin to that of a peripheral neuritis. The pain I am convinced is often well-nigh excruciating. The treatment devised must embrace, so far as possible, efforts to relieve this pain, which lasts for some considerable time. When we rightly consider the condition on a tissue basis rather than a cellular, perhaps Mr. Lake will concede there may be some place, as we suggested, for the judicious use of mild heat in immersion foot as opposed to frost-bite.

I know that others have reported good results from the use of icebags, but we were bound to state as a fact that we relieved the most distressing of our patients' symptoms with mild heat. Posture dealt satisfactorily with the oedema, and it gradually subsided.—I am, etc.,

H. VINCENT CORBETT.

### Expectation of Life in Urinary Tuberculosis not Surgically Treated

SIR,—As a supplement to the late Mr. Hurry Fenwick's interesting memorandum published in your issue of May 6, may I add the following.

Some 35 years ago a young woman consulted me about great frequency of micturition. Cystoscopic examination revealed multiple tuberculous ulcers in the bladder and (by ureteral catheterization) the presence of tuberculosis in both kidneys. She went to Margate for treatment in a sanatorium and subsequently to other sanatoria. Her symptoms gradually diminished and finally disappeared altogether. The urine was from the beginning repeatedly tested on guinea-pigs. The test, positive from the first injection, continued to be positive for several years after all symptoms had disappeared, but eventually became negative and continued so for the several more years over which the testing was continued.

When I last heard of her some 25 years after her first visit to me she was in good health, but her husband developed acute tuberculosis and died of it some 12 years ago. The case shows that even extensive tuberculosis of the urinary tract is not necessarily fatal even if not surgically treated.—I am, etc.,

London W 1

VICTOR BONNEY.

### Chewing-gum or Polypus?

SIR,—I have read with interest Mr. McNeill Love's letter (April 29, p. 600). With 20 years' experience of gastrointestinal radiological examination, I doubt whether any experienced radiologist would be deceived by a patient swallowing chewing gum *provided a thorough examination is carried out*—i.e., screen and film examinations at taking meal and at 1, 2, 4, 6, 24, and 48 hours after taking the meal. Any foreign body must then so frequently change its position, be expelled via the pylorus and pass via the colon, that it is nearly certain to be detected, if it is chewing-gum, by its relative lack of density.

There is a very simple way in which false radiological appearances could be obtained, but, for obvious reasons, I do not mention this; but even then suspicion would arise from careful examination and correlation of the clinical history.

In fairness to recruits genuinely suffering from abdominal trouble, the opposite aspect needs consideration—i.e., the value of these one or two film examinations done without prior preparation at the instance of the Ministry of Labour with negative results. Within the last month I have seen two cases, graded 2 after hospital barium meal examination of curtailed type. Both cases had been examined at different hospitals, and my complete examinations by a coincidence revealed Hirschsprung's disease, which has been confirmed by two different colonic consultants. One case had been labelled "neurosis." I have always maintained, when requested to restrict radiological examinations of any type, that if the examination is not thoroughly carried out it is best entirely

omitted—i.e., in a fracture case, unless thorough, the referring practitioner is better off without radiographic examination, depending on his clinical experience rather than relying on poor films or on single films in one plane.—I am, etc.,

Forest Gate, E.7.

BERNARD LEGGETT.

### Shock Treatment of Mental Disorder

SIR,—Mr. K. W. Monsarrat is perhaps justified in his criticism (April 29, p. 603) of the terms used in the editorial note (April 15, p. 537); nevertheless the question itself, the implied meaning of which is clear, is an ever-present and important one. The problem of the relation of the mind to living tissues still remains, and as Sir Henry Bashford asks, "Are the abnormalities of speech and behaviour in fact due to structural or biochemical defects in the nervous system, including the brain?"

The mind is generally supposed to be a sort of higher attribute of the central nervous system, with the result that Sherrington has said that we have not even a basis for the study of the mind (although as early as 1895 he with Mott made a discovery which, had it been followed up at the time as was intended, might very well have given him this basis).<sup>1</sup>

It seems that a review of the independence (and the interdependence) of the mind and the central nervous system functions is long overdue, and that the value of psychiatry as a "back door" to a scientific physiology of the mind should be reassessed from time to time until a satisfactory physiology of the mind is established.—I am, etc.,

Birmingham.

F. A. PICKWORTH.

### Free Medical Education

SIR,—The report of the Committee on Medical Education of the Royal College of Physicians as published in the Press and the broadcast on its findings by Lord Moran make it clear that the greatest emphasis is placed on free education of the medical student right through his career. Of what follows after, so far as I have observed, the committee has nothing to say, but the inference must be obvious. It would be useless to throw a generation of students on to the employment market without the means to start themselves in practice. If, as seems certain, the buying and selling of practices is to be abolished, it would be an enormous help to those of us who are approaching the age of retirement if some hint were to be dropped as to what our fate is to be. The question of compensation is generally by-passed tactfully when discussion veers in that direction, while the prospect of being able to sell a practice becomes about as secure as one of Hitler's promises. I suggest that it would be good policy to settle this financial question first of all, as until it is disposed of all the other plans and recommendations are no more than wishful thinking.—I am, etc.,

Bridlington.

C. J. GOROON TAYLOR.

### Colonial Medical Service

SIR,—In your issue of May 6 Dr. J. B. Davey referred to a speech made by Dr. Morgan on March 16 in the House of Commons. In the course of this he spoke of the Colonial Medical Service as "one of the worst in the world" and as "a disgrace."

My own concern in the matter is only that of one who has for some years attempted to make an independent study of conditions in our Dependencies. As such, one must be deeply interested to see that the recruitment to a service so vital to the welfare of the Colonial peoples is not prejudiced through the acceptance by professional men in England of an impression that its existing members merit the description which Dr. Morgan has attempted to convey of them.

I am less concerned with the main issue on which he was addressing the House—namely, the merits of a "bureaucratic" medical service. It is not, however, easy to see how medical facilities could be provided in most of our Dependencies other than through a State Medical Service. The private practitioner has begun to establish his position in India; but this has only been made possible by the pioneer work of the Indian Medical Service in introducing European systems

<sup>1</sup> F. W. Mott, *The Degeneration of the Neurone*, 1900, p. 50.

of medicine and surgery in India, and by the high reputation which its members have earned. A similar development is now taking place in Ceylon, and might have been expected to follow from the establishment of the medical schools in Malaya and Hong Kong. It will, we may hope, follow in due course when the teaching institutions now projected for Africa and the West Indies reach their maturity. But in all these cases the State service must for long continue to be the principal agency alike for safeguarding the health of the population and for the local expansion of medical training. Everything, therefore, will depend on the professional work of the members of the Colonial Medical Service and the respect in which it is held.

The service now contains about 700 medical men recruited from the United Kingdom. They have the assistance of about 1,200 medical men locally recruited, and about 600 nurses recruited from the United Kingdom, together with a large body of locally trained nurses. It does not perhaps befit a layman to discuss the professional capacity of this great body of those who are, in much more than a technical sense, public servants. But I am on firm ground in speaking of the almost dramatic change which their efforts have made in the health conditions of some of our Dependencies and the confidence they have inspired in the native peoples to whose needs they minister. Achievements such as those which stand to the credit of the medical services in Malaya—to which more than one foreign observer has paid a tribute—or the success attained in combating epidemic diseases in Africa are not the work of men who merit the slur which Dr. Morgan has cast at them. I hope that this correspondence will afford an opportunity for some qualified authority to speak also of the contributions which members of the service have made to medical research. They are obviously far from negligible.

If the service merits a criticism it is that its numbers are inadequate to deal with the vast problems of health which it has to face. But that is not a matter for which the service itself is responsible, and it is one that will, we hope, be remedied by the growth of the resources of the Dependencies and by the assistance which can now be obtained through the Colonial Welfare and Development Act. I may add that the forthcoming annual report of the Colonial Research Committee should be of interest to medical men in this country, as showing the steps which are contemplated for the strengthening of the service on its research side.

There is no one who would not welcome the assistance which members of Parliament could give in making provision for expanding the strength or improving the organization of the service. If they can do this, it will be of far more value to the Colonial peoples than an attempt to shake their confidence in the competence of the service, or to lower it in the estimation of the medical profession in this country, which must provide the personnel for its expansion.—I am, etc.,

The Athenaeum.

HAILEY.

### Service Medicine

SIR.—As members of another branch of the medical services of the armed Forces may we be allowed to endorse most heartily the sentiments expressed by Air Cdre. Cade and Conybeare, and Squad. Ldr. Hope Lamb in their replies on April 22 and 29 to the anonymous writer of a letter under the above heading in your issue of April 1.

We, too, in pre-war days had considerable knowledge and experience of consultant practice and of hospitals, both teaching and otherwise, and in the last four and a half years have had ample opportunity of comparing them with the organization of the Army Medical Service in various theatres of war. We agree with Cade and Conybeare that the soldier gets better treatment than does the civilian, even in peacetime. Undoubtedly an important factor in the attainment of this result is the fact that the soldier receives no domiciliary treatment except for trivial conditions. When he requires medical attention he must be admitted to an organized medical unit where there are facilities for investigation and treatment under skilled supervision, which could very seldom be made available in an average home.

It is easy to find faults in any big system, and when that system, after a phenomenally rapid expansion, has to cope with medical and surgical problems in every part of the world,

it is surprising that there are not more. In our experience the directorate of the A.M.S. welcomes reasonable criticism, and has accepted many constructive ideas, large and small, from the "civilians in uniform," incorporating them into its highly efficient organization for the increasing betterment of the patient's treatment; he gets the best of two worlds—the experience and organization of an established service together with the expert clinical knowledge and enthusiasm of its "lay" members.

We feel that our R.A.F. colleagues have dealt more than adequately with the specific complaints of the anonymous letter writer. Nevertheless, having had extensive experience of the Army Medical Service both on active service abroad and also at home we strongly deny the allegations of "over-staffing," of "bad staffing," of unnecessary interference with the clinical freedom of the medical officer, and of avoidable lack of equipment or drugs. Taken by and large the utilization of medical officers as supplied from civilian sources shows great discrimination on the part of the administrative authorities, and the meticulous consideration given to individual cases with a view to obtaining the most of their services is as encouraging as it is commendable.

A system must be judged by results; of these the Army Medical Service has reason to be proud, and abundant proof of the high standard of both medical and surgical treatment under most adverse environmental conditions can be seen in comprehensive and authoritative surveys in your own columns, and in those of other medical journals. These results could not have been obtained without good instruments, drugs, and equipment, nor without a high morale among the medical officers.

The Army Medical Service has been faced with an enormous task: it has set itself the highest standard: we feel that it would be most unjust should the biased opinions of one individual lead to anything approaching a general impression that these standards are not being more than adequately maintained.—We are, etc.,

A. E. PORRITT.  
Brigadier.  
E. BULMER.  
Brigadier.

### Medical Certificates for Special Rations

SIR.—On page 598 of the *Journal* for April 29 is a significant and only too tangible shadow of things to come. There is published (without any comment of the B.M.A.) a list of some of the ukases of the Ministry of Food. Among these occurs the outrageous suggestion that, in a certain specified list of diseases (including gout) a special allowance of various foods is available if the doctor in attendance fulfils certain form-filling bureaucratic requirements. It appears desirable to direct special attention to these. To quote the edict: "The certificate must give the clinical and biochemical data on which the diagnosis . . . is based."

Now, Sir, these allowances are to be obtained on the recommendation of the Food Rationing (Special Diets) Advisory Committee, and before they are granted this very detailed certificate is required to be submitted to the local food office. It is hoped that this office will merely act as a forwarding agent: in any case, why, oh why, must the biochemical data and what will inevitably resolve itself into a clinical essay be submitted to the local food bureaucracy? What possible benefit can accrue from the study by lay persons of detailed clinical and biochemical data?

What happens to people unfortunate enough to suffer from a slightly atypical form of any of these specified conditions? Is the victim to be debarred from dietetic treatment because he cannot conform to a textbook description of disease? Are all patients in war, and therefore presumably in peace, to be compelled to suffer only from standardized diseases? What has happened to the principle of professional secrecy? What has come over the profession thus meekly to hand over its prerogatives to, of all things, a local food committee? What has happened to professional pride and honour? If a conscientious doctor has been sufficiently skilful to diagnose any of the given conditions, surely he will wish to treat the case? Can't his word be trusted, and if not, why not? Are we mildly and stupidly going to allow our professional honour and

integrity to be valued at less than the word of a local food committee; or, for that matter, at less than that of a distant advisory council?

For what do we pay our B.M.A. subscriptions? The B.M.A. membership of about 45,000 should give it an adequate income. Are we to get nothing but White Paper questionnaires and the B.M.J. in return for our money? What is the Editor doing to allow this series of edicts and rescripts to pass without any comment or observation on it? Is the Association and its *Journal* to be reduced to a mere transmitting agency for bureaucratic demands?

We have little doubt that there are other instances of these special orders of which some of the profession and certainly the public know nothing. Bureaucracy is like a fungus: it permeates in darkness; let us drag its infiltrations out into the light of publicity. Infiltration is occurring and precedents are being created while we are still nominally a free profession. Excuse like that of the music-hall comedian (don't you know there is a war on?) will be offered. We do know, and it is the oldest war in the world—that of free men against would-be slave-owners.

This, Sir, in our opinion, is merely part of the blue-print for the degradation of the profession and the enslavement of the public—in other words, it is part of the plan to capture and Nazify both. Sir, we, the undersigned, wish most emphatically to record our protest at this unmerited slur on the profession. We wish you to accord this, our considered opinion, the fullest publicity, and thus to direct attention to this widespread and insidious undermining of the essential doctor-patient relationship.—We are, etc.,

H. M. STANLEY TURNER  
(Chairman).

J. O. M. REES.

A. C. DE B. HELME.

DAVID HALER.

Guildford Practitioners' Group.

### Ophthalmic Surgeon and Optician

SIR,—As one who, as a Fellow of the British Optical Association before qualifying in medicine, has had some experience of both sides of the question, may I welcome the concise plan put forward by Mr. J. P. Spencer-Walker in your issue of April 22 under the title "The Ophthalmic Surgeon and the Optician"?

Addressing a group of opticians recently, I gave it as my conviction that the opinion that opticians were incapable of accurate refraction was fast dying a natural death, and it is refreshing to find confirmation in the form of Mr. Walker's proposals, proposals strikingly similar to those which I placed before the meeting referred to above, and with which the optical executives are also conversant.

Mr. Walker's paper was purposely only an outline and it would be unfair to criticize it on matters of detail, but there are points which I can see will only become *faits accomplis* by the most cordial and understanding staff work between ophthalmic and optical representatives. Here are four which occur at once to me: (1) The optical majority are not yet ready to give up the "shop." (2) The powerful dispensing associations would find it hard to turn their members into ophthalmic opticians. (3) The optical societies may not readily sink their identities in a new "Ophthalmic Opticians Council." (4) Not every optician will regard being a medical auxiliary as conferring an "enhanced status."

Two statements by Mr. Walker are vital in considering the whole problem. First, that stressing the necessity for dual examination, by both surgeon and optician, for *everyone*; and, secondly, its corollary "fear is unnecessary for there is work for all."—I am, etc.,

H. F. MELHUISH, D.O.M.S.

Western Ophthalmic Hospital, London, N.W.

SIR,—While we greatly appreciate the spirit which stimulated Mr. J. R. Spencer Walker's article, we must point out that the suggested plan appears to be based on certain errors, which, if uncorrected, might lead to unprofitable discussion. Mr. Spencer Walker says: "The ophthalmic surgeon is concerned to a large extent with the physiological and pathological defects of the eye, and the optician with the appliances used to correct certain of these defects." Even though it is clear

that Mr. Spencer Walker appreciates the capability of the optician to refract, since he says, "The refractive error may be found by either the surgeon or the optician," it is obvious that these statements indicate an insufficient appreciation of the scope and status of ophthalmic optics, which has been defined as: "The field of work concerned with the function and conservation of vision, the correction of anomalies due to anatomical and physiological defects, and the appliances used for these purposes."

While refraction, therefore, must remain the essential function of the optical practitioner, ophthalmic optics is a much wider field of work than refraction only; orthoptics, colour vision, night vision, and visual problems in industry all come within the legitimate sphere of ophthalmic optics. The fact that medicine has concerned itself with certain aspects of ophthalmic optics—e.g., orthoptics (when, it should be noted, it was immediately necessary to create an auxiliary service)—does not invalidate the above conception of ophthalmic optics as a whole.

This, however, is only one indication of the unsuitability of ophthalmic optics being controlled by medicine. Ophthalmic optics has developed as a distinct and individual field of work for very definite reasons. It has developed on distinct and separate lines from quite early times. It is based on the science of physics and is concerned with the adequacy of healthy eyes, thus differing from ophthalmology, which is traditionally occupied with disease. These constitute the essential differences between the two professions in their fundamental outlook and fields of work.

Had it not been for the absurd and illogical antagonism which has prevented a true assessment of the position, medicine must have officially recognized the development in the capabilities of the modern optical practitioner which has been taking place over a long period. As an example of the development of his academic standing it should be noted that the honours diploma of the British Optical Association is accepted by the University of Manchester for admission to a research course for the degree of Master of Science in the Faculty of Technology. Both it and the honours diploma of the Spectacle Makers' Company are also accepted by the University of London for admission to special courses at the Imperial College of Science and Technology, successful completion of which entitles candidates to the Diploma of the Imperial College (D.I.C.). In addition they are approved by the War Office in lieu of a university degree in connexion with enlistment for certain scientific duties which may not be more fully referred to for security reasons. It is safe, therefore, to say that the potential value to the community of the technique of ophthalmic optics has been gravely and grossly underestimated by official medicine.

The second error is related to the first and concerns Mr. Spencer Walker's point regarding the necessity of control. Here there seems to be some confusion. Medical control and State control are two different things and for very different purposes. *State control* is clearly in the interests of the community, the addition of medical control not necessarily so.

Statutory control of the opticians' professional services does exist in regard to one section of the community only, but is denied to all others. The Ophthalmic Benefit Approved Committee of the Ministry of Health, in respect of National Health Insurance patients only, recognizes refraction by the optician and controls the supply of optical appliances. In addition, the opticians' services are officially used in Royal Ordnance factories, where a very satisfactory relationship exists between the doctor and the optician.

That ophthalmic optics is linked with medicine where the detection of pathological conditions is studied is insufficient reason for medical control of the whole of our technique. The optical profession acknowledges with special gratitude the public spirit of those individual ophthalmologists who have helped us to become efficient in this aspect of our work. Proficiency could indeed have been reached more easily if organized medicine had assisted in providing facilities, and Mr. Spencer Walker can be assured of our willing co-operation regarding any sound proposals in this direction. Medical representation on any statutory Controlling Board would, as a result, be welcomed.

It should be noted that the optical profession has never attempted to trespass on what it regards as exclusively medical territory, and we agree emphatically with Mr. Spencer Walker's statement that the optical practitioner can never become absorbed into medicine, since this would necessitate medical registration—as wasteful and unnecessary a basis for optical practice as it would be for dental practice.

It is submitted that the field of public health is now too wide to be covered adequately by a single profession, and that so great is the knowledge needed in this sphere that its successful application has required, and must in the future require, the development of separate and complementary professions within the general fabric of the health service.

Little difficulty will exist in devising a basis for co-operation and collaboration with medicine once a proper relationship has been established, and while we do not claim equal seniority with the

ophthalmologist in any Public Health Services scheme, an auxiliary status is entirely unsuitable to the importance of our technique and the record of our service. Freedom to develop is the life blood of the optical profession as it is to the medical profession, and in the words of Mr. Willink, "A profession needs these things . . . if it is to attract the right people and to keep on achieving the highest results."

As it is impossible for us in the space of this communication to produce all the available evidence in support of the claims made, we would ask Mr. Spencer Walker and those interested in this important matter to examine all the relevant facts presented in a pamphlet, "The Place of the Optical Profession in the Health Services of the Nation" issued by this *ad hoc* committee and obtainable from the address given below. (The committee represents protective bodies and examining bodies recognized by the Ophthalmic Benefit Approved Committee.) We are confident that no considered opinion will then be forthcoming that it is in the interests of the community or ultimately of medicine itself to assume control of the technique of ophthalmic optics.—I am, etc.

W. B. BARKER.

Chairman, Beveridge Report Committee (Optical Profession)

65, Brook Street, London, W.

### First Aid according to St. John's

SIR,—It is indeed refreshing to read Dr. M. E. Lampard's criticism (April 8, p. 505). As both a teacher and examiner I endorse everything he says. The manual, in the hands of a first-aid, is much like a loaded tommy-gun in the hands of a child. As a "refresher" to a junior H.S. it might have its use, but for whom it is intended it is a menace. I have often shuddered at the impish satisfaction of the candidate who has, sometimes successfully, adjusted a tourniquet, and my daily prayer has been that, should I be in need of this application, he may not be at hand at the critical moment.—I am, etc.

Exford.

CLAUDE A. P. TRUMAN.

SIR,—That so much mumbo-jumbo is taught in first aid is due partly to the vanity of its medicine men and partly to the enthusiasm of its expert laymen. First aid needs some Ostlers to cut away its dead wood and fungus. Yet what hope is there when we get such unimaginative and dogmatic arguments as those of Dr. M. M. Scott, who recoils in horror at any honest criticism of his sacrosanct St. John textbook. (Incidentally, about the first-aid treatment of a fractured humerus: an expert young M.O. from North Africa told us Home Guard doctors that there they slung all arm fractures in a broad bandage. Will the Dr. Scotts please note.)

It looks as if Civil Defence, anxious to fill up the long hours of its personnel, has forced the nation into making a cult of first aid and us into being its arch-priests. No reasonable person can deny that the teaching of first aid needs complete overhauling; there is so much bunkum in it.—I am, etc.

London, S.W.4

H. J. POWELL.

### Intelligence and Season of Conception

SIR,—I have just received your number of March 4 in which Surg. Cmdr. J. A. Fraser Roberts states as a fact that children conceived during winter months are on the average more intelligent than children conceived during summer months. I have not yet had a chance to see any subsequent correspondence or of consulting any of the authorities he quotes. Surely one explanation of this fact is that children conceived during winter and born in July-October more closely fit in with the school year, which normally begins in September. Children born during the spring either attend school for the first time 6 months younger than the others or make this first attendance in the middle of the school year and thus miss much of the groundwork. This principle applies not only to young children attending at the age of 5, but also to those who go to public schools at the age of 14.—I am, etc.

W. F. VEALE.

A. B. Loveman and R. P. Morrow (*Amer. J. Syph. ven. Dis.*, 1944, 28, 79), who record 8 cases of intra-urethral chancre, maintain that the condition is not so rare as the literature suggests. Early diagnosis is important. Careful palpation of the urethra for circumscribed induration in all cases of urethritis, unexplained inguinal adenopathies, and all genital lesions should be made. The final diagnosis should be made by discovery of *T. pallidum* from the local discharge or the inguinal lymph nodes.

## Obituary

E. HURRY FENWICK, C.B.E., F.R.C.S.

Mr. Edwin Hurry Fenwick, who died at his home in Bedford Gardens, London, on May 5, was for many years a leading urologist and a general surgeon on the staff of the London Hospital, where he had received his early training. He qualified in 1880, and after taking the F.R.C.S. in 1882 studied methods at clinics in Leipzig, Berlin, and other Continental centres. During his period as surgeon and lecturer on clinical surgery at the London Hospital Hurry Fenwick examined in physiology for the English Conjoint Board; he was also consulting surgeon to the West Herts Infirmary. He served during the last war in the R.A.M.C.(T.), reaching the rank of lieutenant-colonel and receiving the C.B.E. in 1919, mainly in recognition of his work as officer in command of the Military Hospital, Bethnal Green, and of the military section of the London Hospital.

From 1919 to 1925 he held office as president of the International Society of Urology, and he was president of the Urological Section at the 17th International Congress of Medicine. He was also a corresponding member of the French, Russian, German, Italian, Belgian, American, and Spanish Associations of Urology. He wrote much on his specialty, having no fewer than ten books to his credit, published between 1889 and 1911; and only the other day, at the age of 87, he contributed a note to these columns on "Expectation of Life after Nephrectomy for Urinary Tuberculosis." He was one of the earliest English surgeons to take up electric light cystoscopy in the 'eighties, and he had a very large experience of operations for urinary calculus and vesical tumours.

Dr. DAVID ALEXANDER, C.M.G., died in Glasgow on April 2, having been in retirement for some sixteen years. After obtaining the L.R.C.P., L.R.C.S.Ed. and L.R.F.P.S.Glas. in 1896, he filled several appointments before joining the West African Medical Staff in 1903. He obtained the certificate of the London School of Tropical Medicine with distinction in 1904, and his first appointment was to the then Northern Nigeria. In 1905 he obtained the D.T.M. & H.Camb. and in 1910 the D.P.H. of the Irish Colleges. Early in his career he realized the importance of public health, and he was in the first batch of appointments to the new branch of the service—the Sanitary Service. He must be given no small share of the credit in bringing about the improved conditions of living which led to the rapid advance of the West African Colonies. He worked and left a lasting mark in Sierra Leone and in the Gold Coast before returning to Nigeria as Director of Medical and Sanitary Services. A big man, physically and mentally, David Alexander had a wide knowledge of general medicine and of public health, and he also took a warm interest in medical research. He was a born administrator and gained both the affection and the respect of his staff. Modest in regard to his own attainments, he was intensely proud of the C.M.G. awarded to him while serving on the Gold Coast. In Nigeria he did the spade-work which led to the formation of the Medical Training College, and he was the instigator of many other advances. His old colleagues will regret the passing of a valued friend, and many in West Africa will feel the loss of an outstanding figure in the development of their country.—A. C.

The death on April 19 of Dr. NORMAN JAMES McCASKIE removes one of the senior practitioners of the South Kensington district who had spent the whole of his post-hospital career in Onslow Square and the neighbourhood. Himself the son of a medical father, whom he joined in practice early in this century, he was educated at Westminster School, Caius College, and St. George's Hospital, where he won the University Scholarship and held the usual resident appointments with marked credit to himself. He qualified M.R.C.S., L.R.C.P. in 1899, became M.B.Camb. in the following year, and M.D. in 1903. McCaskie was one of those very intelligent, hard-working, highly educated men who did not, in the era before the present impulse to specialization, disdain the life of a general practitioner. He possessed not merely a thorough knowledge of medicine and surgery but the kindness, the tact, and the discretion which attracted a wide circle of grateful patients. Without any affectations, he yet comported himself with dignity, and was the sort of doctor to whom patients came for advice outside their bodily ailments. For many years he had his younger brother, Dr. Harry McCaskie, as his partner; and he had also a

brother-in-law, Dr. Swete Evans, in our profession. Among his own colleagues he was very popular in a wide circle; and it is safe to say that few men of his generation in London adhered consistently to as high a code of professional ethics as did Norman McCaskie. He was visiting apothecary to St. George's Hospital, an honorific title highly valued among the alumni of the medical school there.

Dr. DAVID MITCHELL MACDONALD died at his home at Arncliffe, Westmorland, on May 2 at the age of 74. Originally a pharmacist at Aberdeen, he graduated there M.B., Ch.B. in 1900, proceeding M.D. in 1906. A year later he took the D.P.H. of St. Andrews and in 1914 became F.R.C.P.Ed. He was in successful practice at Dunkeld, Perthshire, and at Alloa, finally in semi-retirement at Arncliffe. He had served as captain, R.A.M.C., with the Scottish Horse in 1914-18, and his work in the present war was in hospitals in the Birmingham area, where he made an independent clinical study of the sulphoamides, especially in children. Author, during 60 years, of *The Student's Pocket Prescriber* he had just completed revising for press the 12th edition, the 19th printing since the first edition in 1882, much of the treatment sections having been rewritten in the light of recent advances. Dr. Macdonald was also responsible for one of Livingstone's Catechism Series, *Materia Medica*, which ran into six editions, these and other publications reflecting his early interest in pharmacy.

#### Correction

Prof. G. Grey Turner writes:

Acting on information, from what I regarded as an unimpeachable source, of the very much regretted demise of my friend F. B. Lund of Boston, and actuated by warm attachment, hastened to pay a tribute which was published in your issue of April 15. It was therefore a joyful surprise to hear of his survival in vigorous health and to have confirmation in a cheerful letter written by his own hand and received two days ago. Very much regret any distress or annoyance which may have been caused to the doctor or his family by my inadvertence. I am sure that your readers will join with me in wishing Fred Lund that continued health and vigour which proves him to be so very much alive! I would further express my very sincere apologies for breaking the long record of accuracy for which the *British Medical Journal* is so well known.

\*\* We wish to join with Prof. Grey Turner in his expression of regret for pain inadvertently caused and of pleasure at knowing that Dr. Lund is in good health.—Ed., B.M.J.

## Universities and Colleges

### UNIVERSITY OF LONDON

The following appointments to the Senate for the period 1944-8 have been made: *Faculty of Medicine*, Sir Francis Fraser, M.D., F.R.C.P. (reappointed). *General Medical Schools*, the Right Hon. Lord Moran, M.D., P.R.C.P. (reappointed).

### UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examination indicated:

THIRD M.B., Ch.B.—PATHOLOGY AND BACTERIOLOGY: Ruth A. Ainsworth, J. J. Burke, Alexander Dowling, Eve G. Field, Harold Jackson, Thomas Jackson, Joan E. Nuttall, Margaret W. Oliver, E. L. Peel, A. H. C. Ratcliffe, Margaret Taie, Marie R. West, W. McC. Whittaker.

### UNIVERSITY OF DUBLIN

The thirteenth John Mallet Purser Lecture will be delivered by Prof. Thomas Walmsley, M.D., of Queen's University, Belfast, in the Physiology Theatre of the School of Physic, Trinity College, on Wednesday, May 24, at 4.30 p.m. Subject: "The Unity of the Organism."

### ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council on May 11 with Sir Alfred Webb-Johnson, President, in the chair, Mr. J. B. Hume was re-elected a member of the Court of Examiners for a further period of three years as from June next. Mr. W. H. Collins was invited to accept appointment as a Hunterian Trustee. It was decided not to award the Hallett Prize on this occasion.

Diplomas of Membership were granted jointly with the Royal College of Physicians of London, to the candidates whose names appear in the report of the meeting of the Royal College of Physicians published in the *Journal* of May 6 (p. 638) and to D. M. Montgomery and A. J. S. Perfect.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the College held on May 2, with the President, Dr. A. Fergus Hewat, in the chair, Dr. R. E. Verney (Edinburgh) was introduced and took his seat as a Fellow of the College. Drs. T. McLaren Galloway (Carlisle), W. D. Henderson (Woking, Surrey) and H. P. Tait (Edinburgh) were elected Fellows.

## The Services

Surg. Cmdr. D. MacK. Craig, D.S.O., R.N.V.R., has been awarded the R.N.V.R. Officers' Decoration.

Temp. Surg. Lieut. J. H. Fisher, R.N.V.R., has been mentioned in dispatches for outstanding skill, resolution and devotion to duty in successful landings at Anzio.

Capt. V. J. McKenty, R.C.A.M.C., has been awarded the M.C. in recognition of gallant and distinguished services in Italy.

The M.B.E. (Military Division) has been awarded to Capt. (Temp. Major) J. F. A. Forster, I.M.S., in recognition of gallant and distinguished services in the field.

Cpts. G. O. Hughes, and E. H. Jones, R.A.M.C., and Cpts. R. N. Chopra, J. N. Ghosh, and K. K. R. Nadiu, I.A.M.C., have been awarded the M.C. in recognition of gallant and distinguished services in Italy.

### CASUALTIES IN THE MEDICAL SERVICES

Wounded.—War Subs. Cpts. J. H. Brown and J. Greenhaugh, R.A.M.C.

Wounded or injured.—Temp. Surg. Lieut. R. J. Alcock, R.N.V.R. Missing, presumed killed.—Temp. Surg. Lieut. N. A. Douglas, M.B.E., and Temp. Acting Surg. Lieut.-Cmdr. S. L. Lord, R.N.V.R. Wing Cmdr. RICHARD MALHERBE OUTFIN who was killed in a flying accident on April 29 at the age of 36, studied medicine at Guy's Hospital and qualified L.M.S.S.A. in 1935. He was appointed to a commission in the Medical Branch of the Royal Air Force on May 4, 1936, and at the time of his death was senior medical officer at a group headquarters over-seas.

### DEATHS IN THE SERVICES

By the death of Col. JAMES CRAWFORD KENNEDY, C.B.E., R.A.M.C. (ret.), on April 4, at Ash, Surrey, at the age of 65 the Service has lost an officer of high scientific attainments. He was educated at Edinburgh University and graduated M.B., Ch.B. in 1900, obtained the M.D. with a gold medal for a thesis on Malta fever in 1908, and took the D.T.M. & H.Camb. in 1909 and the M.R.C.P.Ed. in 1925. He entered the R.A.M.C. in 1900 and rose to the rank of brevet colonel in 1923 and colonel in 1928. The most important of the many posts he held were membership of the Mediterranean Fever Commission, which established the goat's milk theory of infection and led to the practical abolition of this serious disease from the military forces at Malta and from the British Navy; the assistant professorship of pathology and the professorship of medicine at the Royal Army Medical College; consultant physician to the British Forces in Turkey, 1922-3 and to the British Army 1922-9; and A.D.M.S. Poona in 1930-2, on the termination of which appointment he retired. Among the distinctions he gained were his appointment of Hon. Physician to the King, 1923-32, and the award of the C.B.E. (Military Division) in 1923. He served in the war of 1914-18 in India and Mesopotamia and was mentioned in dispatches. After his retirement Col. Kennedy served on the Ship Surgeons Subcommittee of the B.M.A. in 1938-9 and held the post of medical inspector to the P. & O. and associated shipping lines. He wrote a number of papers, chiefly on tropical medicine and bacteriology. His recreations included golf, lawn tennis, and yachting.

Col. LIONEL AUGUSTINE JOSEPH GRAHAM, A.M.S., who died of cerebral thrombosis on March 24 while on active service with the M.E.F., qualified L.M.S.S.A. in 1915 after studying at Cambridge and Guy's Hospital. D. G. E. writes: To his colleagues in the R.A.M.C. "Nap" was well known as an experienced physician and administrator who had specialized in venereology and dermatology. He had served in England, Egypt, Palestine, Syria, India and Malaya, and in the present war he served with the B.E.F. at Army Headquarters in France; on his return from France he went out to the M.E.F., where he was in command of a general hospital. When at Cambridge he won his half-blue at lawn-tennis, and kept up his keen interest in the game throughout his career. He regularly represented the R.A.M.C. at this game, and at Singapore in 1935 he won the open singles in the Services tournament against a Wimbledon player of exactly half his own age. He had a marvellous eye for any ball-game, and could, for instance, place his services with uncanny accuracy, first in one corner and then the other of the service court. He was also very successful at golf and won several competitions at Singapore and in India. The Army Medical Services have lost a most popular and efficient officer and doctor, and the Army a very good all-round sportsman. His brother officers and colleagues will cherish the memory of "Nap" as one of their best friends.

# The WELLCOME MEDICAL DIARY

Medical men who have not yet ordered a copy of the 1945 edition of the Wellcome Medical Diary are urged to do so without delay. The edition will be limited and orders should be placed *now* to avoid possible disappointment or inconvenience later.

*please order NOW  
for 1945!*

## Expectorant and Sedative

Glycurrant is an expectorant and sedative preparation, particularly suited to dry coughs, such as that of chronic bronchitis. Its carefully planned composition includes the juice of ripe black currants, an agent which is well known for its soothing effect on the pharynx, and which gives a distinctive, delicious flavour to the mixture.

**DOSAGE.**—It is recommended that one teaspoonful of Glycurrant Cough Linctus undiluted should be sipped slowly every 3 or 4 hours. The size of the dose and the frequency of administration are varied at the physician's discretion.

In bottles of 2½ and 5 oz., at 1/8 and 3/1  
*including purchase tax*

## GLYCURRANT COUGH LINCTUS

Containing Codein Phosph. 0.1; Ext. Scll Lq 0.5; Ext. Senec. Hq 1.5; Venthol 0.01  
Ext. Prun. Ferol. 1.5; Acc. Lib. Nig 16.0; Lq Tolu 8.0 per cent. v/v.

## ANOREXIA IN CHILDHOOD

Among the many complaints of childhood on which medical advice is sought, anorexia with associated cessation of gain in weight, is probably the most common.

Of the likely causes of this lack of appetite, dietary deficiency, particularly hypovitaminosis B<sub>1</sub>, is, according to many authorities, the most

important. Anorexia associated with gastro-intestinal atony is certainly the earliest and most constant sign of vitamin B<sub>1</sub> deficiency and its presence, by lessening the intake and decreasing the absorption of food, tends to establish a vicious circle in which the tissue content, not only of vitamin B<sub>1</sub>, but of the other essential food factors, is progressively lowered.

### THE EFFECT OF INCREASED VITAMIN B<sub>1</sub>

Controlled clinical trials have shown that the administration of vitamin B<sub>1</sub> is specific in preventing and curing anorexia and associated gastro-intestinal functional disturbances such as atony, constipation and diarrhoea when these are of nutritional origin. Since other factors of the vitamin B complex may be implicated in such syndromes, the whole B complex has been recommended,<sup>1</sup> and it is common practical experience that a course of treatment with Bemax

leads to rapid and striking improvement in the clinical picture.

In deficiency states the lack of more than one food factor is nearly always present, so that, in treatment, a combination of the known vitamins should generally be administered. This is a further sound reason why, in treating anorexia of childhood with the vitamin B complex, Bemax should be employed.

### THE MULTIPLE FACTORS OF BEMAX

Since, even under normal peace-time conditions, it was not a simple matter to construct a diet providing the optimal adult intake of vitamin B<sub>1</sub>, and since the daily vitamin requirements of children are much higher than those of adults, the provision of Bemax to young children offers the best treatment for anorexia and associated sequelæ of hypovitaminosis B.

Bemax provides, at time of manufacture, approximately:

Vitamin A	280 i.u. per oz.	Manganese	4.0 mg. per oz.
Vitamin B <sub>1</sub>	240-420 i.u. " "	Iron	2.7 mg. " "
Vitamin B <sub>2</sub> (riboflavin)	0.3 mg. " "	Copper	0.45 mg. " "
P.P. factor	1.7 mg. " "	Protein	33%
Vitamin B <sub>6</sub>	0.45 mg. " "	Available	
Vitamin E	8 mg. " "	Carbohydrate	39%
		Fibre	2%
		Calorific Value	104 per oz.

<sup>1</sup> J. Amer. Med. Assoc., 1938, 110, 953.

Further particulars concerning Bemax from Vitamins Ltd. (Dept. B.X.U.1), 23, Upper Mall, London, W.6.

### TRADE 'DECICAIN' MARK (The Original Product)

#### Brand of AMETHOCAINE HYDROCHLORIDE

The anæsthetic action of 'Decicain' is ten times that of cocaine, and it may be used therefore in correspondingly weaker dilutions in a wide range of indications, notably otolaryngology and ophthalmology. Solutions of 'Decicain' are stable and can be sterilised by boiling.

Issued in tablets of gr. 1½ in tubes of 10, and solution 2%, bottles of 1 oz.

### TRADE 'FRANOL' MARK

#### Brand of ANTI-ASTHMATIC

'Franol' combines antispasmodics known to have a relaxing action on the musculature of the bronchi, phenobarbitone, theophylline and ephedrine. Results of extensive clinical trials indicate that symptomatic relief was obtained in a very fair percentage of cases of bronchial asthma of allergic origin.

Issued in tablets, in tubes of 20 and bottles of 100

### TRADE 'ANAESTHESIN' MARK THROAT TABLETS

#### Brand of BENZOCAINE

This tablet combines sodium borate and menthol with a local anæsthetic in the form of ethyl-p-aminobenzoate. The active organic compound acts as a surface analgesic and anæsthetic, and benumbs the part which it bathes. Indicated pre- and post-operatively in oral surgery and in painful affections of the tongue.

Issued in tablets, in bottles of 20 and 100 (Prices reduced recently)

Made in England.

BAYER PRODUCTS LTD. AFRICA HOUSE, KINGSWAY, LONDON, W.C.2

## Medical Notes in Parliament

### National Water Policy

Opening, on May 3, a debate on water supply, Mr. WILLINK said the Government intended to introduce measures for the conservation and better use of the country's water resources, the improvement of the administration of water supply, the further extension of public water supplies and sewerage in rural localities, and the better management of rivers. The Government's proposals were largely derived from the reports of the Central Advisory Water Committee. Twenty-nine River Boards would take over the powers for prevention of river pollution, for which some 1,600 authorities at present were responsible. There was in the country ample water for all needs. What Parliament had to do was to protect and control the resources and see they were equitably distributed. A Bill would at once be produced to provide substantial Exchequer assistance for the extension of rural water supplies and sewerage. There would be general legislation in the next Session. Some 2,000,000 people in England and Wales had not piped water supplies in their houses or within easy reach.

Arguing against the proposal that there should be a National Water Board Mr. R. S. HUDSON said water could not be divorced from housing, health, and drainage, which were the concern of the Ministry of Health.

On May 4 Mr. Willink introduced the Rural Water Supplies and Sewerage Bill.

### Patulin Clinical Trials

Answering Colonel Lyons on May 4, Mr. ATTLEE said that, in view of the inconsistent results of preliminary trials of patulin in the treatment of common colds, the Medical Research Council accepted an invitation to organize and control clinical trials on a larger scale. These trials had been in progress during the winter months in industrial establishments and in a small number of schools. Results were being analysed, and a statement might be possible soon. Patulin was not at present generally available. Unless there was definite evidence of its value, production on a large scale could not, under present conditions, be justified.

### National Health Service and Workmen's Compensation

On May 3 Dr. MORGAN asked whether the Minister of Health, in planning for the new National Health Service, considered the advisability of taking steps for Workmen's Compensation for health workers exposed to infectious diseases and ailments in the course of and resulting from their occupation; and whether his Department had submitted a request to the special Home Office Workmen's Compensation Committee for the scheduling of pulmonary tuberculosis as an occupational health risk in sanatoria and other institutions. Miss HORSBROUGH replied that the scheduling of diseases under the Workmen's Compensation Act was a matter for the Home Secretary. The principle always followed—and endorsed by Departmental Committees on the subject—was that diseases to be scheduled must be so specific to the particular employment that their cause by that employment could be established in individual cases. This could not be applied to the ordinary infectious disease or tuberculosis. Mr. Willink had made no recommendations to the Home Secretary. She did not think that the National Health Service proposals affected the principle involved.

### B.M.A. and the Ministry of Health

On May 11 Dr. RUSSELL THOMAS asked Mr. Willink if the Council or any executive body of the B.M.A. acted in a general way in an advisory capacity to his Ministry.

Mr. WILLINK replied that his practice was to consult the B.M.A. on matters affecting the professional interests which it represented. Neither the Council nor any of its executive bodies acted in an advisory capacity to his Department in the manner Dr. Russell Thomas suggested. That was the province of his Medical Advisory Committee and of other special advisory bodies constituted by him for the purpose. He also stated that no member of the B.M.A. was responsible for any part of the White Paper, and that no members of his Medical Advisory Committee were paid as such.

### Serving Doctors' Views on White Paper

Mr. SHEPHERD inquired on May 11 what the Minister of Health was doing to ensure that medical officers, either prisoners of war or serving in the Forces, were given full opportunity of expressing their opinions on the proposed new health services.

Mr. WILLINK replied that the B.M.A., with the co-operation of the Service Departments, had sent copies of the White Paper

—provided by his Department—to all doctors normally domiciled in this country who were serving in the Forces or were prisoners of war. The Association invited the opinion of these doctors on the proposals. Views received would be collated and the results made available in his discussions with the profession's representatives.

### Nuffield Trust Surveys

Asked on May 11 by Mr. MESSER what were the terms of reference of the Nuffield Trust Hospitals Survey Committee and if any limitation had been placed on the surveyors, Mr. WILLINK said the special committee of the Trust had been concerned with the position arising out of the Government's statement on hospital policy in October, 1941, and in particular with the arrangements for hospital surveys conducted by the Trust on his behalf. The work of the surveyors was to survey the hospitals (other than mental hospitals and mental deficiency institutions) and to advise what modifications or developments of the existing facilities would be needed to provide a co-ordinated hospital service.

### Leprosy in Tanganyika

Mr. CREECH JONES inquired on May 10 what steps had been taken in Tanganyika as a result of the investigations of Dr. Muir into leprosy five years ago. Colonel STANLEY replied that after Dr. Muir's visit in 1938 it was agreed between the East African territories that a leprosy specialist for East Africa should be appointed, but no appointment had as yet been made owing to war difficulties. A recent conference of directors of medical services raised the question again, and the Government of Tanganyika expressed its willingness in the Legislative Council to appoint a whole-time specialist for Tanganyika if a suitable man could be obtained. That Government also decided, as a result of Dr. Muir's visit, to set up two main leper settlements under Government operation. One of these had already been established in the Southern Highlands Province for 1,100 patients. It was intended to establish another in the region of the central railway line. The settlement at Chazi was established in 1941 by lay workers paid by the British Empire Leprosy Relief Association, with the assistance of the native authorities. The site was discovered to be malarious and too remote for effective medical supervision, and it was therefore regarded as unsuitable for development as a Government station, and a decision was taken to close it. In view of the delay in finding a suitable site for a permanent station this settlement at Chazi was being continued as a temporary measure. There were at present 14 leper settlements or camps in the country maintained by Government or native authorities and 15 by missions. Compulsory segregation was not in force; the Governor reported that it would in any case be impracticable, and modern practice was generally not in favour of wholesale segregation, especially where considerable numbers of non-infectious cases might be involved.

**Removal of Smallpox Cases.**—On April 25 Mr. VIANI asked the Minister of Health the date or dates of the removal to Clandon of the patients or nurses at, or connected with, Mount Vernon Hospital found to be suffering from smallpox, and the dates of death of the two fatal cases. Mr. WILLINK: One case was removed to Clandon Isolation Hospital on March 1, four on March 2, one on March 3, two on March 12, one on March 13, and one on March 15. Of the cases taken to Clandon, the patient admitted on March 1 died on March 3, and one of the four patients admitted on March 2 died on March 6.

**Disposal of Infected Sputum.**—Replying on April 26 to Dr. MORGAN, Mr. WILLINK said that attention to the sterilization and disposal of sputum was an elementary principle in the treatment of tuberculosis. In any inspection of tuberculosis institutions by his medical or nursing officers inquiry about it was made as a matter of course, and any necessary advice was given. His medical advisers were fully apprised of modern developments in this matter. He had recently arranged, through his Standing Advisory Committee on Tuberculosis, for a statistical inquiry into the incidence of tuberculosis among sanatorium nurses. Dr. MORGAN asserted that in some institutions with tuberculous patients round about the London area the sputum was sterilized by dry-heating the mugs containing the sputum in the kitchen of the institutions where patients' meals were prepared and cooked. Mr. WILLINK said he was not aware of such circumstances, and such a practice was much to be deprecated. If Dr. Morgan gave particulars of any institution in which it had come to his notice, he would look into the matter.

### Notes in Brief

The Minister of Health announced recently that the proportion of insured persons who have not chosen panel doctors is at present about 6%, but probably most of these are recent entrants into insurance who will exercise their right of choice at some future time. The average proportion before the war was between 2 and 3%. No information is available as to the proportion of insured persons who choose a doctor but do not make use of his services.

No. 17

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 29.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of:

are for: (a) The 126 great towns i

(b) London (administrative county).

The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

† Includes puerperal fever for England and Wales and Eire.

‡ Owing to evacuation schemes and other movements of population, birth and death rates for Northern Ireland are no longer available.

## EPIDEMIOLOGICAL NOTES

## Discussion of Table

In England and Wales there was a very large fall of 729 in the notifications of measles. Compared with last week 118 fewer cases of pneumonia were recorded, but 157 more of scarlet fever, 76 more of whooping-cough, and 14 more of dysentery.

The lowered incidence of measles was general throughout the country, but was specially marked in Lancashire, Kent, London, and Middlesex, which reported respectively 161, 88, 76, and 67 fewer cases than last week.

In Yorks West Riding there were 53 more notifications of scarlet fever than last week. The fall in notifications of acute pneumonia continued to be greatest in the south; the returns for this disease in the combined south-eastern and south-western counties have fallen by over 50% during the past three weeks. Yorks West Riding, with a rise of 25 cases, supplied the only large variation in the incidence of diphtheria.

Notifications of dysentery in the outbreak in Derbyshire, Heanor U.D., rose from 12 to 30. The other large returns were those of London 37, Lancashire 23, Surrey 19, Hertfordshire 11.

In Scotland the only rises in incidence were of scarlet fever and of whooping-cough, respectively 24 and 63 more cases than last week. The increase in scarlet fever was fairly general, while that for whooping-cough occurred mainly in Glasgow, where the notifications rose from 95 to 165. In Glasgow there was also a big drop of 73 in the measles notifications. The total notifications for dysentery fell by 16, but the incidence remains at a high level; the largest returns were Edinburgh 26, Glasgow 14, Renfrew County 17.

In Eire the total notifications of diphtheria and measles fell by 14 and 49 respectively, while those for whooping-cough rose by 23.

## Diphtheria in Scotland

According to the Secretary of State for Scotland 756 cases of diphtheria, of which 5 were fatal, occurred during the second half of 1943 in immunized children up to 15 years of age, and 69 cases with no deaths in immunized persons over that age. The position as regards non-immunized persons was:

	Cases	Deaths
Children up to 15 .. ..	1,599	85
Persons over 15 .. ..	922	15

The numbers of immunizations against diphtheria recorded in Scotland during the years 1941 to 1943 are:

	Under 5	5 to 15	Total
1941 .. ..	153,913	464,792	618,705
1942 .. ..	57,690	71,892	129,582
1943 .. ..	29,826	16,060	45,886

Mr. Johnston furnished the following figures on May 4:

	1942	1943
Deaths from smallpox in Scotland .. ..	25	Nil
" " post-vaccinal encephalitis .. ..	13	1
" " other effects of vaccination .. ..	5	2

## Smallpox in Naples

Forty-eight cases of a mild type of smallpox were reported in Naples during the three weeks before May 7. No death have been reported. There were also 5 cases of smallpox in Taranto, where 2 deaths have occurred.

## Week Ending May 6

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,646, whooping-cough 2,432, diphtheria 548, measles 2,035, acute pneumonia 680, cerebrospinal fever 72, dysentery 259, paratyphoid 4, typhoid 5.

## "Air-borne Infections"

Air travel has made it necessary to consider new safeguard against the incursion into this country of major epidemic diseases, such as smallpox or typhus, since it is now possible for a person contracting such a disease abroad to arrive here by air and proceed to his destination before expiry of the incubation period and before the manifestation of symptoms. No such case has yet come to notice, but the Ministry of Health has adopted precautionary measures. In future a person arriving by air in this country will be given a card containing a warning notice that if he falls ill during the 21 days after arrival he should immediately consult a doctor and hand the card to him. This card asks the doctor at once to inform the appropriate

Medical Officer of Health if any acute notifiable disease is found or suspected.

Certain particulars are entered on the card before it is handed to the passenger, which in conjunction with other measures will make it possible to bring contacts who were fellow passengers on the same aircraft under medical surveillance if the case notified is one of smallpox, typhus, plague, or cholera.

## Medical News

At a meeting of the Medical Society for the Study of Venereal Diseases to be held at 11, Chandos Street, Cavendish Square, W.1, to-day (Saturday, May 20), at 2.30 p.m. Prof. A. Fleming will give an address on penicillin.

The annual general meeting of the Socialist Medical Association will be held at the Large Conway Hall, Red Lion Square, W.C.1, on Sunday, May 21, at 11 a.m. The morning session will be for members only, but the afternoon session, from 2.30 p.m. to 5 p.m., when there will be a discussion on the White Paper, will be open to all.

The Food Education Society announces that on Monday, May 22, at 3 p.m., in the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, Mr. Vernon Charley, Ph.D., will give a public lecture on "The Contribution of Fruit and Vegetable Juices to Health in War and Peace."

At a meeting of the Eugenics Society on Tuesday, May 23, at 5 o'clock, in the Rooms of the Royal Society, Burlington House, Piccadilly, W., Dr. Margaret Hadley Jackson will speak on a medical service for the treatment of involuntary sterility. All interested in the subjects are invited to attend.

At a lunch discussion at the Housing Centre, 13, Suffolk Street, Haymarket, S.W., on Tuesday, May 23, at 1.15 p.m., Alderman W. Hyde, trustee of the Nuffield Provincial Hospital Trust, will speak on health services and town planning.

The 45th annual meeting of supporters of the Lebanon Hospital for Mental Diseases (Astruryeh, near Beirut) will be held on Thursday, May 25, at 5 o'clock, in the Hastings Hall of B.M.A. House, Tavistock Square, W.C.

At the next meeting of the Medico-Legal Society to be held at Manson House, 26, Portland Place, W., on Thursday, May 25, at 5.30 p.m. Dr. Robert Forbes will read a paper on "The Medico-Legal Aspects of Artificial Insemination." Members may introduce guests; tea at 5 o'clock.

The new British Council medical film, *Accident Service*, will be shown at the Curzon Cinema, London, W.1, at 5 to 6.30 p.m. on Friday, May 26, and will be introduced by Sir Alfred Webb-Johnson. A limited number of tickets are available and may be obtained by application to the Medical Department, the British Council, 3, Hanover Street, London, W.1. The film is concerned principally with the miners' rehabilitation centre at Berry Hill Hall, and has been made with the closest collaboration of Mr. E. A. Nicoll, the director of the centre. *Accident Service* will be preceded by a film called *Cambridge*.

A refresher course in tuberculosis for tuberculosis officers and medical practitioners will be held on June 13, 14, and 15, at Girton College, Cambridge, and Papworth Village Settlement. After opening remarks by Sir Walter Langdon-Brown, the following lectures will be given in the mornings at Girton College: "Differential Diagnosis of Pulmonary Tuberculosis," Group Capt. R. R. Trail; "Some Medical Problems in the Administration of Tuberculosis Schemes," Dr. Norman F. Smith; "Diagnosis by X Rays," Dr. Peter Kerley; "Rehabilitation and Local Authority Schemes," Dr. F. R. G. Heaf; "Non-pulmonary Tuberculosis," Prof. J. Paterson Ross; "Collapse Therapy," Mr. J. B. Hunter. Demonstrations will be given each afternoon at Papworth. The fee for the course is £2 2s. As accommodation is strictly limited, applications should be made as soon as possible to Dr. Harley Williams, Tavistock House North, Tavistock Square, London, W.C.1.

The British Council has been permitted to print a small edition of *British Medical Bulletin* for sale in the United Kingdom. It is estimated that the current (1944) volume will contain about 280 foolscap pages, plus an index. It will appear in not more than 12 parts. As no advertising matter is accepted, the cost of the *Bulletin* is relatively high. The subscription for the whole volume is 21s., and 14s. for the volume less those parts (1-4 inclusive) which have already been published. Single parts may be purchased at prices based approximately on 2s. for a 24-page issue. The British Council points out that the primary purpose of *British Medical Bulletin* is to interpret British medicine to the overseas reader who would not normally consult the medical journals published in this country. It contains reviews, abstracts, book notes, and a list of the contents of current British medical and cognate journals. Copies of the *Bulletin* are already available for consultation in most medical libraries. Application for annual subscriptions or for single parts should be addressed to B.M.B., 3, Hanover Street, London, W.1.

## Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Aitology Western, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE EUSTON 2111. TELEGRAMS Articulate Western, London.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association TELEPHONE: EUSTON 2111 TELEGRAMS Mediterra Western, London.

B.M.A. SCOTTISH OFFICE 7, Drumsheugh Gardens, Edinburgh

### ANY QUESTIONS?

#### Vesiculation after Vaccination

**Q.**—If a vaccination with calf lymph does not result in vesiculation, but merely in slight erythema, can one assume that the person will be immune from smallpox?

**A.**—After vaccination three kinds of lesion may occur: (1) typical vaccinia, where vesiculation begins about the fourth or fifth day, is accompanied by considerable local reaction, and progresses to scabbing about the 10th day; (2) an accelerated, or vacenoid, lesion, where some immunity exists, and the reaction (papules and vesicles) reaches its height in three to five days; and (3) an evanescent lesion occurring within twelve to twenty-two hours, known as the reaction of immunity and characterized by local erythema or a few papules, but without vesiculation. This last is presumably the type of reaction described by the questioner, and it indicates a high degree of resistance to smallpox. To make sure, however, that this slight lesion is not merely a reaction to local trauma from the scarification, vaccination should be repeated, particularly if the patient is an infant being vaccinated for the first time. In a susceptible person vesiculation must occur before vaccination can be regarded as successful. Thus Henderson and McClean (*J. Hyg.*, 1939, 39, 680), who inoculated volunteers intradermally and subcutaneously with a specially purified vaccine lymph, found that immunity to subsequent vaccination by scarification was obtained only if there were vesicles at the site of the primary inoculation. Vaccinia virus seems to multiply specifically in the skin, and an epidermal lesion is essential for successful vaccination.

#### Otitis Externa

**Q.**—Would you briefly outline the causes and treatment of otitis externa?

**A.**—Common types of external otitis are: (1) *Furunculosis*. Treated by insertion of wick soaked in glycerin and mag. sulph. paste changed daily; and hot fomentations or other heat. Incision avoided if possible. (2) *Erysipelas and cellulitis of meatus*. Reduce swelling by packs of 2% aluminium acetate solution. Later paint in 1% aqueous sol. gentian violet. (3) *Impetigo*. Paint or drop in 1% aqueous sol. gentian violet after cleaning. (4) *Eczema*. Clean, and then paint in a zinc preparation—e.g. linimentum calamineae, to which may be added a coal-tar preparation for pruritus, as desired. (5) *Seborrhoeic dermatitis*. Often associated with similar condition of scalp, which must be treated locally—e.g. lin. calamineae, with occasionally an ointment containing 1% acid salicyl.

#### Cousin Marriage

**Q.**—I have been consulted by a man who wishes to marry his first cousin, the daughter of his mother's brother. He is anxious to know if this degree of consanguinity would have any adverse effect upon the possible family. Would they be peculiarly liable to any defects, mental or physical, or to any disease in particular? So far as I know both parties are healthy.

**A.**—Marriage between blood-relatives differs from any other marriage only because the partners tend to carry more of the same hereditary factors than do unrelated people. There is no doubt that in the human species there exist many undesirable recessive genes. Individually they are rare, however. Thus, should one partner carry such a gene, the chance that an unrelated person will carry the very same gene is very small. Only when both do so can the defect appear in the offspring. But if the person bearing the gene marries a first cousin, the chance is one in eight that that person will carry it also. The possibility that an undesirable recessive trait may appear in the offspring is one of the inescapable risks inherent in any marriage. It is certainly much increased in a consanguineous marriage. Full knowledge is not yet available, but the indications seem to be that harmful recessive genes are not numerous enough to make that risk, though increased, more than a small one.

absolutely. It does not appear to be the sort of risk that ought to deter the informed person, and it would be a bold physician who would advise against a cousin marriage simply because it was a cousin marriage. One important point might be stressed. If the cousins do marry, and if they should prove unlucky, they will be left in no doubt. Provided, as will be true in the great majority of instances, that no recessive defect appears, they should not blame their blood-relationship for any of the ordinary disappointments, physical or mental, which may attend the development of their children.

Of course, should the joint family history reveal the occurrence of defects possibly due to recessive genes, a more detailed investigation of the particular case would be necessary.

#### Pilonidal Sinus

**Q.**—What is the prognosis of an untreated pilonidal sinus? What are the chances of complete cure in radical operation? Is there any palliative treatment short of complete excision? Why is pilonidal sinus so rarely mentioned in the JOURNAL? Is it so rare in England? I have seen quite a number of cases here (in Malta).

**A.**—A pilonidal sinus is unlikely to heal spontaneously, the common story being of repeated inflammatory attacks. Palliative treatment can consist only in the antiphlogistic measures adopted during the attacks of inflammation. Unfortunately it is impossible to guarantee cure even after a radical operation, though it is true that the more thoroughly the operation is performed the less the likelihood of any recurrence. The track is often difficult to follow, even with the help of dyes, and in many instances the coccyx has to be partially excised to ensure its complete eradication. Pilonidal sinus is quite common in this country; there have been some articles published on the subject, though it is true that they have not been in proportion to the frequency of the condition. It is one of those backwaters of surgery which attract few explorers.

#### Diagnosis of Night Blindness

**Q.**—A policeman, promoted sergeant, had to revert to constable shortly after promotion because of alleged night blindness; and very soon afterwards he had to leave the service for the same reason. He is a strong, healthy man with a good appetite, and his diet has always included more than adequate vitamins A and D. There was no complaint of night blindness when he had to do night duty as a constable. There appears to have been no attempt at treatment, and I cannot convince myself that he is, in fact, night blind. There are no apparent changes in cornea, lens, media, or retina, and an oculist to whom he was sent replies, "I have no means of ascertaining his adaptation for dark vision." What are likely to be the causes—other than psychological—of sudden onset of nyctalopia, and how can its existence be proved or disproved (especially in a possible malingerer)?

**A.**—Night blindness is a very difficult condition to assess. The scientific methods of estimating night vision are too complicated for general use. Those of less complexity tend to suffer from a lack of exactitude which would render them suspect in a court of law. The difficulty in the case of suspected malingerer is that, when special apparatus is used, the patient realizes the nature of the test, and one's judgment is largely dependent on the answers given. The following technique, requiring the minimum of divergence from the normal routine of eye testing, may be of some help. Refract the patient in a completely dark room using as dim a light as possible or placing the refraction lamp as far from the mirror as feasible. Prolong the examination short of arousing the patient's suspicions so that his eyes shall become as dark-adapted as possible. While the room is still darkened, put on the trial frame if not already in position and slip in the appropriate lenses. It is suggested that "fogging" should be used—i.e., too strong a plus lens or too weak a minus lens—together with a really dark glass or Crooks B2 and B together. At the same time the patient should be told that the usual illumination is being used on the test type, which is only switched on after the dark glass had been placed in position. Assuming that the examiner's night vision is good, a comparative estimate of the patient's night vision can be obtained.

The cases of true night blindness where there may be difficulty are practically confined to retinitis pigmentosa sine pigmento and congenital nyctalopia. In the former there is absence of any pigment, but the usual progressive attenuation of the retinal vessels and increasing optic atrophy and blindness. In the latter there are no observable changes in the fundus and no progression to blindness.

It has been shown that unless there is gross lack of vitamins A and D treatment with them is of little avail.

#### Treatment of Parkinsonism

**Q.**—I have heard that a Continental treatment for Parkinsonism is to draw off 10 c.c.m. of blood from the patient, wait till R.B.C.s have settled, and then inject the serum intramuscularly. I can find no literature about this treatment. Is there anything in it?

**A.**—No, there is not. A host of treatments have been tried, since the condition is so common, chronic, and disabling; and besides auto-serum therapy, vaccines, non-specific protein therapy, and

fixation abscesses have been tried. A full account of the literature will be found in the first three reports of the Matheson Commission for Encephalitis Research (New York 1929, 1932, and 1939).

#### Paraldehyde Intravenously

**Q.**—We are informed that paraldehyde given by intravenous injection is an effective hypnotic in cases of delirium not responding to morphine, hyoscine, etc. Can you confirm this and describe the mode of administration?

**A.**—Paraldehyde may be given intravenously and thus induces sleep very rapidly. The usual dose is 4 c.c.m. as a 10% solution in saline. The effect usually passes off in two to three hours. The injection may be repeated.

#### Rosacea associated with Seborrhoea

**Q.**—What is the most up-to-date treatment for rosacea in a woman who for many years has suffered from seborrhoeic dermatitis of the scalp also? Is there any connexion between the two ailments? State of digestion and condition of bowels and kidneys are normal.

**A.**—Rosacea occurs in seborrhoeic subjects and is therefore usually associated with seborrhoea of the scalp. A 2% sulphur and salicylic acid ointment attacks the seborrhoeic basis and improves the facial eruption. Small doses of x rays given by an expert are beneficial. Condiments, hot drinks, tea, and coffee should be excluded or reduced. The psychological factor influencing the flush reaction should not be forgotten.

#### Dacryocystitis and Sulphonamides

**Q.**—In the JOURNAL of March 11 I find an article on the use of the sulphonamides in ophthalmia neonatorum (p. 353). I think I read somewhere that they can be used in cases of dacryocystitis. If so, can you tell me the dosage internally, and whether there is anything against their use in this condition?

**A.**—The sulphonamides are of no value in the treatment of the chronically inflamed mucosa and of the mechanical obstruction in chronic dacryocystitis. In acute dacryocystitis there is generally pus formation, and this requires incision and packing. The sulphonamides are useful as an immediate post-operative measure in these cases in helping to clear up the residual infection. The initial dose for adults is 2 g., and a maintenance dose of 1 g. 4-hourly for two to three days. Sulphanilamide powder might with advantage be introduced whilst packing the wound.

## LETTERS, NOTES, ETC.

#### Fluorine in the Diet

Major G. C. PETHER, R.A.M.C., writes: Some years ago, while on holiday in Derbyshire, I visited some quarries in the millstone-grit area east of the Derwent. In many of these grindstones were made, and I understood that these were used both for metals and for grain. But inquiry at a local flour mill showed that no local stone had ever been used there, though in the past imported French burr stones had been used, these now being replaced by steel rollers. I believe the French stone contains fluorine, and a calculation was made to correlate the rate of wear of the stone with the quantity of flour produced. I have forgotten the figures, but evidently flour thus produced will contain a quantity of finely divided stone which is possibly absorbed. This source of fluorine has almost disappeared from our diet because most flour is ground by steel rollers now. I understand that mineral deficiencies in plants may often be discovered from examination of their foliage. If fluorine deficiency can be detected in this way then foodstuffs which have too little fluorine could be improved by suitable fertilizers. Dental surgeons will no doubt study the diseases of bone attributed to fluorine deficiency or excess.

#### First-aid Textbooks

Mr. F. E. EVANS (Northolt) writes: As a "first-aider" of many years' experience may I be permitted to add a few words to the correspondence on first aid as taught in the textbooks of St. John B.R.C., St. Andrew's, etc. It is well known among all experienced non-medical instructors of first aid that these textbooks are merely methods of instruction. The novice is instructed by these orthodox methods only as means of gaining an end—i.e., as a form of drill to enable him to become efficient and to use his own initiative controlled by existing circumstances when and where a casualty should occur. After all, it does not need much imagination to be able to substitute, say, a rifle for a long Liston's splint in a fracture of a wound of the thigh, or use a bayonet scabbard when a forearm is injured. It is essential that a form of drill should be used to gain that trained mind which will enable a "first-aider" of only small experience to improvise by whatever means he has to hand, and these textbooks are undoubtedly the best material we have at present on account of their more or less uniformity. I do agree, however, that some of the chapters, particularly that on burns, could be revised in view of the experience that has been gained in the present war.

## WITH THE EIGHTH ARMY IN THE FIELD\*

BY

Brigadier CHARLES DONALD, O.B.E., Ch.M., F.R.C.S.

*Consulting Surgeon, Army Medical Service*

To journey through the Western Desert, into Tripolitania and Tunisia, across to Sicily, and up into Italy with the Eighth Army was a great privilege. No one could travel in that fine company without an ever-present pride in the British fighting-man. His feats of arms are well chronicled. To those travelling closely in his wake the wonder ever grew at the sight of the obstacles he overcame and the defences he stormed. Added to these he had the changing yet constant privations of the field and of the front line, heat and sandstorms, cold and mud, forced marches and tedious delays, pestilential flies, shortage of water, monotonous though ample rations, and other lesser trials. He deserved then, when he was wounded, the best that could be offered.

It is not easy to describe the efforts made to provide surgery worthy of the patient. The shifting backgrounds prove hard for the writer to depict and for the unacquainted reader to visualize and understand. Surgery in the field is influenced by many external circumstances. Some of these at first-sight must appear almost ridiculous to the civilian surgeon. It thus becomes a specialty, not, by and large, a highly difficult technical specialty, but a specialty none the less. Any surgeon whose experience is purely civilian must approach it with a mind open to change. Otherwise there will be disappointments, and quite likely disasters.

Field surgery I would define as the care and treatment of the soldier from the time of wounding to his arrival at the base hospital area in which he will complete his treatment and be returned to duty or invalided. The term "forward surgery" I prefer to restrict to the original primary operative treatment. There is need for such distinction, especially in any description of these campaigns. For such base hospital areas were hundreds, often thousands, of miles from the fighting. It might be a matter of weeks before the wounded reached the base. Sometimes that was due to military difficulties and exigencies. Sometimes it was deliberate: many a man owes his life to being held and nursed in the field. There is thus more to be thought of than the primary operation. There is the treatment afforded over a period of time and often at a series of points in a varying and sometimes prolonged chain of evacuation which is still "in the field." Field surgery thus embraces forward surgery and maybe much more besides.

The aims of field surgery are to save life and limb, to give such treatment as will promote rapid healing where these are unlikely endangered, and to ensure that the patient passes in comfort to the base. It is a slight catalogue, but the thought and organization needed to achieve a high standard are immense, and affect the administrator as much as, or even more than, the surgeon. Ever-varying conditions call for flexible and adaptable minds. What was done in the last war in France did not necessarily suit the desert; what was done in the desert did not necessarily suit Italy.

### THE CAMPAIGNS

The period dealt with covers the three campaigns in Africa, Sicily, and Italy. In the last it deals with events up to the

"winter line" of 1943-4. The first, to save confusion with the First Army, also in North Africa, will not unfittingly be termed here the Desert Campaign. A short description of the campaigns from a surgeon's point of view is an essential prelude to more specialized considerations.

### The Desert Campaign

The Eighth Army advanced from el Alamein to Tunis, some 2,000 miles, in under seven months. To understand how surgery kept up with this it is necessary briefly to go back a little. The essence of desert warfare is mobility. In the earliest desert campaigns, with their swift and far-moving thrusts and counter-thrusts, the weakness of relatively immobile cumbersome casualty clearing stations had been shown up. New methods were needed. Surgery, like the fighting services and supplies, had also to be put on wheels. By the time of el Alamein there had gradually been developed by the previous consulting surgeon to the Middle East Forces, Major-Gen. D. C. Monro, a group of mobile units. This had been done by giving the light sections of some casualty clearing stations their own transport, and by the formation of small mobile field surgical teams. The latter consisted of surgeon, anaesthetist, a few trained orderlies, a staff car, and a lorry in which to carry gear, surgical and personal. While the mobile light sections were able to function autonomously the field surgical teams were independent in name only. They constituted a fluid mobile surgical potential, usable where most needed but dependent for many things on some host unit. This latter was either a casualty clearing station which needed surgical reinforcement, or the main dressing station of a field ambulance when the team was being used as a detached forward surgical centre. Their mobility was given them especially for the latter purpose. They could then keep up more closely with the fighting, and at field ambulance level afford surgery to casualties whose further journey back to the casualty clearing station would be lethal or hazardous. In practice later about half of these teams reinforced casualty clearing stations; half worked more forward at main dressing stations. The mobile light sections of casualty clearing stations could act similarly but more independently.

Like the progress of science the desert advance was a succession of jumps. Static sometimes for a month or more, the army would suddenly leap to action and in a week or two move forward a few hundred miles. The dispositions of surgical units thus varied. The static periods represented preparation for stiff battles to be fought, such as, more particularly, el Alamein, Mareth, and the Wadi Akarit. Casualties in formidable numbers had then to be anticipated. In the intervals there were pursuits, with minor enemy rearguard actions and few casualties. Accordingly the same alternating disposition of units was repeated several times. At the set pieces there was a concentration of casualty clearing stations some 15 to 30 miles behind the line and in front of this, at suitable points, field surgical teams with some of the main dressing stations. When the break through occurred the latter moved forward with their field ambulances, and the casualty clearing stations moved one by one, in leap-frog fashion, until they were stretched out as

\* Based upon experience as forward consulting surgeon, M.E.F. and A.F.H.Q., in October-November, 1942, and January, 1943, to February, 1944.

a chain of daily staging posts back to the base, the railhead, an embarkation point, or an advanced base. By the time the next set battle was to begin they were, in more or less degree, gathered into a similar concentration, linked backwards to some fresh disposal point. This was a campaign mainly on a narrow front with few lateral roads. Only occasionally did outlying units require to be sited far from the main coast road.

Thus surgery kept up with the fighting-man and watched him on his often-protracted journey to the base. The railway track was soon left behind. Benghazi harbour took some time to be clear for hospital ships. Tripoli to Benghazi is 700 miles of bleak desert road. Tripoli harbour also needed clearing. There was still a long stretch of desert road before Sfax and Sousse and the pleasant greenness of Tunisia.

The difficulty to both medical administrator and surgeon lay in the long road evacuation that was often necessary. To the former it meant the diversion of casualty clearing stations and field ambulances to act as staging posts; to the latter it meant that his patients would undergo an added strain on their strength and resistance, a strain which it was essential to ease for the seriously wounded. While the administrator has to keep the forward areas as clear as possible, the surgeon, knowing the value of rest, wishes to have little or no movement for his post-operative patient. A trite saying occasionally expressed, that the most efficient casualty clearing station is an empty one, pays little heed to sense and less to humanity. There must be give and take between administrator and clinician. In the Eighth Army a happy and harmonious balance was achieved.

The desert campaign was essentially a tented affair for casualty clearing stations and field ambulances. Rarely were there suitable buildings. Operating vehicles were gradually discarded as cramping and labour-making. The difficulties associated with tents were the limitations set by the necessary tent-poles, the absence of floors, the regulation of warmth, lighting and blackouting, fly-proofing and sand-proofing, and dispersal. These would take much description, just as they took much labour to overcome. Most would agree to flies and sandstorms as the greatest trials. Dispersal of tents, to limit damage by possible bombing, was an irksome handicap. Too wide dispersal slowed the tempo, particularly of the operating theatre. To have pre-operative and post-operative tents at a distance, even 50 yards, from the theatre was tiresome and annoying, especially in a moonless period. It could be ridiculously easy to get lost in darkness "black as Egypt's night."

Gradually, as the Luftwaffe waned, pre-operative and post-operative tents, to cope with serious casualties, were brigaded to the theatre. The surgeon could then keep an eye on what was to come and what had gone, without passing across a blackness filled with the snares and gins of guy-ropes and slit-trenches, did he veer from the straight and narrow. The Luftwaffe's activity was restricted to night excursions, and there was gradually diminishing annoyance from this quarter. But it was early found advisable to pitch theatres well away from the main road, which naturally was a guide to a bomber, his machine-guns, and his cannon-guns.

It would have been ideal to be followed up at a close distance by general hospitals which could retain and nurse the patients. This was impossible to any great extent. If the enemy is retreating he must not be let rest. Fighting materials and stores must come first. Supply difficulties in this campaign were enormous. It was a German general who said that the desert was a tactician's paradise and a quartermaster's hell. A general hospital set up near Benghazi was in a few weeks 800 miles behind. The fall of Tripoli gave the much-prized opportunity of an advanced base for supplies and services. Till then everything, except limited urgent stores which were flown, had come up the 700-odd miles from Cyrenaica by road. Hospitals were set up in suitable buildings in Tripoli as soon as possible. Before they could all be established the hunt was well on. The earliest were soon full—sick have to be thought of as well as wounded—and all served until the end more as casualty clearing stations than as retaining hospitals. But they could deal with special casualties in a more satisfactory fashion, and they could retain those whose need was great, before evacuating them by ship. Later, when the battle had gone some 300 miles beyond Tripoli, hospital ships put into Sfax to obviate the need for the long road journey.

It would be a pity to leave this background of the desert campaign without trying to recapture the feeling of enthusiasm in the medical units. They vied with one another to put up the best show and to get the best seats at the drama. Full of zest for the chase, they were cock-a-hoop when moved to the front of the procession; left behind, they good-humouredly cursed their lot and settled down to what they derisively called "coffee-stalling." "Coffee-stalling" was important and necessary, and they knew it. But there was not the relish of being up with events and dealing with fresh casualties with the sound of the guns ahead. The medical units came from the United Kingdom, from New Zealand, from South Africa, from India and, for a short time, from Australia. Of the great Dominion only Canada was not represented; she was soon to be.

### The Sicilian Campaign

The now-well-established mobile field surgical units and light sections of casualty clearing stations, born out of necessity for desert warfare, fitted well into the diffuseness of the earliest days of the Sicilian invasion. They landed at different points with field ambulances and were immediately dealing with the most serious casualties. Scaled down to a reasonable minimum of equipment, some of the early units had to wade ashore carrying their panniers. Their transport followed quickly from the landing-craft. Lying off the invasion beaches were hospital ships and carriers. These were fed with casualties by craft plying between them and the shore, and their surgical staffs, reinforced by extra teams for the occasion, wasted no time in getting down to work which they continued to perform during the voyage to Africa or Malta.

The early rapid advance of the fighting troops allowed the getting ashore of the full strengths of the casualty clearing stations in the next few days. Certain of these followed the fighting upon the wide front, again with some field surgical units a little ahead; others, after bearing the brunt of the initial days, stayed and established a medical centre in Syracuse, to which the foremost transferred their patients for further transmission by ship. Within a fortnight general hospitals were beginning to arrive and to take up position in and around Syracuse.

The conditions in Sicily for the fighting troops were not enviable. The weather was oppressively hot, the close vegetation made it stifling, there was a high humidity, the flies were more numerous and vicious than anyone even from Egypt could have imagined, and the filth in the villages was widespread. Small wonder was it that everyone sighed, as they had thought they never would sigh, for the open spaces of the desert and the Mediterranean breeze which here seemed stifled. On and on, march and fight, fight and march, with little sleep the infantrymen pushed over rugged country. The enemy was to be given no respite. The strain our men endured in these pitiless days had its effect when they were wounded. Their resistance was much diminished. The surgical units had kept up with them, but the casualty often had more need of sleep than surgery. Many of those with abdominal wounds, whom from desert experience one would have expected to live, perished out listlessly on the second or third day after operation.

The relative lull in front of Catania, while progress from the west was being made, did not afford as much relief as it might have done. All roads, medically, led to Syracuse. They were poorish roads and wound wearily up and down hill. To the travelling wounded they were a trial, and the haven of rest seen ahead in Syracuse was for many to prove a mirage. For malaria had now become a problem. The general hospitals which had arrived were soon at full stretch. The next phase might require all the beds. Back and forth went the hospital ships and the planes. Only the wounded in immediate danger could be retained for that rest which they all needed and all richly deserved.

Etna dominates all eastern Sicily. With the fall of Catania the mobile units were soon on the move either on the roads flanking the mountain northwards or, the Canadian element, coming in from the west. Again there was rough country with congested difficult roads for the ambulances. Demolished bridges had been relatively few up to now; henceforth they were to be numerous. The rough diversions which had to be used until the engineers had built new crossings, and the delays caused, in the congestion of pursuit, by the new ones' being

one-way only, contributed additionally to the strain on the wounded. The field surgical units were again paying a handsome dividend in obviating such journeys for the bad cases, even though the distance was now only to Catania. Fortunately, the campaign was soon to be over.

For the Sicilian invasion several casualty clearing stations and field surgical units had dropped out of the Eighth Army temporarily and others had taken their place. The latter came either from the First Army, with which they had had experience in North Africa, or from non-fighting areas, either the United Kingdom or lines of communication abroad. There was thus a mingling of surgeons—veterans and novices in acquaintance with war and war wounds. Differences there were bound to be, both between those of the two armies, working on different lines on a different type of front, and between these and the new-comers. What the latter had most to realize, what is so often omitted in systems of war surgery or in training, were the strains and risks of post-operative transportation. The First Army surgeons had been working in a more static way, but in a countryside more cultivated than the desert and more akin to the Sicilian conditions. The little differences were interesting to observe. The new-comers in a few weeks had become hardy veterans.

Surgeons were now working usually, if not always, with a roof over their heads. Schools, monasteries, churches, and

dwelling-houses were the commonest buildings used. Handier in most ways, they had their drawbacks. Cleanliness is not the most striking feature of Sicilian villages. (The most salient feature would have appealed more to the midwife than to the surgeon: Mussolini's bounty had worked wonders, if his Army had not.) The R.A.M.C. orderly who saw a pre-war recruiting poster which read "Join the Army and see the world" and retorted with "Join the R.A.M.C. and scrub it" had every justification in Sicily. But the scrubbing was done, and if sepsis could not always reach satisfactory heights it was not for want of effort. The vexations of taps which did not run, plugs which pulled but gave no issue, globes which did not illuminate, and flies which were ubiquitous did not add to the pleasures of patients, surgeons, and attendants.

#### The Italian Campaign

The Eighth Army initiated the invasion of Italy, on September 3, 1943, with its little-resisted landing in and around Reggio. Again the mobile units found their niche in the early diffuseness, and again, in the rapid race up the forefoot of Italy, they kept in touch. It is not to be imagined that they moved daily, leaving a trail of operated-upon casualties in their wake. They leap-frogged one another. And soon once again there was a chain of staging posts stretching back to the Straits of Messina over some 300 miles. As before, the swifter the pursuit the fewer were the casualties. The race, it will be remembered, was to aid the hard-pressed American Fifth Army at Salerno. Immediately the contact was established the Eighth Army swung to the east coast, and, with Bari and Taranto behind it, the early chain could largely be discontinued. But another was required as the army pushed northward.

The first real checks to progress did not occur till the weather broke; some two months after the Reggio landing. In this time the army had covered some 500 miles. From then on the picture changed. Cold, rain, snow, and mud altered the face

of a countryside previously blessed with the sun and with the fruits of the earth in profusion. The numerous wide dry riverbeds filled with the rain and the melting snow from the hills. The equally numerous one-way bridges, which replaced those demolished, again caused congestion and delays. Unmetalled roads crumbled. But the army was determined not to be static. The Trigno and Sangro were crossed. The difficulties encountered in getting casualties back across the swollen stream of the latter, before bridges were firmly established, were overcome by manhandling, by amphibious "ducks," and by the devotion of field ambulance orderlies. And so on to St. Vito and Ortona. Every advantage had to be taken to place mobile units well forward; a scorched-earth policy had left few buildings for casualty clearing stations, and it was bad country for tents. But the obvious and the unforeseeable delays on the roads proved the greatest indication for surgical units close up.

#### The West Italy Campaign

The landing at Salerno and the subsequent campaign on the west coast were not Eighth Army business. But the American Fifth Army, whose campaign it was, had a substantial British component, the medical units of which had all seen previous service with the Eighth and First Armies. Later there was to be a further mingling. Unofficially at first, officially later, I was able to observe the surgical aspect of this campaign, and it

would be a pity not to include briefly the contrasting picture. As will be remembered, the landing was a hotly contested affair. For some days the invasion force was restricted to an area in which medical units and their patients had to share whatever was hurtling around. Field surgical units came early with beach parties, and casualty clearing stations followed in the next few days. Digging down and sand-bagging were required to an extent not needed previously. While patients were received very promptly after

wounding there was the drawback of their post-operative care in tents. A canvas roof was not convincing protection from bomb, shell, or, more likely, large splinters from anti-aircraft fire, and the racket that went on from the latter alone was hardly rest-giving. The natural outcome was a rather more expeditious transfer to hospital ships than would have been considered advisable under less harassing conditions.

Soon, however, the advance progressed, and eventually Naples was taken. This allowed of general hospitals in buildings; but here again, as at Tripoli, they could at first be little more than final staging posts to the ships, though able to retain patients on the danger list. The specialties were soon installed—chest, facio-maxillary, and neurosurgical. With the forward casualty clearing stations only some three or four hours away, there was no need for the specialties to move from the hospitals.

There were few suitable buildings near the line, and most casualty clearing stations went under canvas as the line moved forward. This was pleasant until the weather broke. Then the scene changed, and duckboards and other squelchy reminders of Flanders in the last war reappeared. It was in keeping with the relatively static nature of the fighting. But there was slow but sure nibbling going on ahead, and surgery was keeping up by means of smaller advanced centres, one of which consisted of as much as the light section of a casualty clearing station with three additional field surgical units. Such could be accom-

modated in the only suitable building available at the time of the early Garigliano fighting. Elsewhere the field surgical units were working in pairs. The wounds at this time were very commonly multiple and severe from mortar fire.

The conditions on the two sides of Italy were now almost identical.

### Some Other Features

Some other features of the campaigns may be given to fill in the picture.

The mine-fields of Alamein were largely meant to hinder tanks and vehicles. By the time Benghazi was reached, the anti-personnel mine, chiefly exemplified by what is known as the S mine, had made its appearance in numbers soon to become profuse. Roughly the size of a 2-lb. jam-jar and actuated by the tread of a foot, this infernal machine after a few seconds' delay springs five or six feet into the air and explodes, to scatter some 300-odd ball-bearing-like metal marbles with a high initial velocity. As the enemy retreated he planted more and more of these, not only in protective fields where he was making a stand but everywhere that his pursuer might walk—on the road verges and off the roads at points where transport might pull in for the night. The multiple wounds frequently caused by these mines were later to be excelled in severity by the multiple wounds of the several-barrelled mortars which were so fully exploited by the enemy. Such multiple wounds cause great anxiety to the surgeon. Not only is shock pronounced, but one or more of the wounds is often a serious one—a fractured femur or a penetrating abdominal injury. By the time the surgeon has dealt with this he has to face a dilemma of how much more the patient will withstand.

While wounds from anti-personnel mines became for a time more numerous, those from anti-vehicle mines became fewer. The latter frequently took the form of severe compound injuries of the feet, from the underneath explosion. The harassed enemy, fortunately, had less time to plant so many of these later, and more efficient mine-detecting apparatus largely abolished a type of wound which led almost inevitably to amputation.

The army had moved off from el Alamein in shirts and shorts in October, 1942. It changed to battle dress for the winter in the desert, and was back in drill for the end of the African battle, the Sicilian adventure, and the early part of the Italian campaign. Retained clothing around missiles—a potent source of trouble—was never the feature in the dry desert, even with battle dress, that it became in the wet and mud of Italy.

While at el Alamein each forward casualty clearing station could only have one reinforcing team, by the time Italy was reached the number of field surgical units had been so increased as to allow of several at important points. The tenor of the working day was thus much evened, and efficiency rose. An experiment made in the intervening period, with the object of increasing the forward surgical potential during rush periods, is worthy of note. What were called reserve surgical teams were formed. They were drawn from base general hospitals, they consisted of personnel only, and they were meant to relieve, or spell with, a regular team, using the latter's equipment. The emergency over, they returned to their hospitals for the busier period at the base. A relief surgeon by himself is little use; a whole team is needed.

### SURGICAL UNITS IN THE FIELD

The tactical disposition of units is the administrator's business. He sees the whole picture—the present one and the likely future; he is in touch with the other Services. In these campaigns, as may be imagined, he required breadth of mind and resource in changing situations. A rough idea of the principle behind the dispositions has been given above. How did surgery best fit into this?

The casualty clearing station is the key unit of field surgery. Reinforced by field surgical units, it can have several operating teams to take their spells of duty and remain fresh. It offers, because of the sisters on its establishment, a high standard of nursing. It has ample beds for serious casualties. It has good lighting, x rays, and suitable tents. It offers some refinements in the way of invalid food and hospital comforts. It can usually be sited clear of noise. Its position is generally assured for some weeks. Thus every wounded man who can with little

risk be passed back to a casualty clearing station, after first aid and resuscitation, will receive the best attention possible in the field.

For the desirable early treatment of wounds, therefore, the foremost casualty clearing stations were sited as far forward as possible, consistent with their retaining these attributes and with their conforming to the demands of the military situation, geographical and tactical. The latter, which might be handicapping to the ideal, had to be accepted. The lightly or moderately severely wounded could reach them without deleterious effect. But it was not always so with the serious casualty. The time factor and the strain factor came into play. These will be referred to when discussing evacuation of casualties.

The wounded who, after first aid from their regimental medical officer and supplementary attention with perhaps plasma transfusion at the advanced dressing stations of field ambulances, reached the main dressing stations of the latter were sorted into three groups. The first were those requiring resuscitation, the second those requiring operation as an urgent measure; the third group comprised all others. The first group naturally included many of the second. Resuscitation of course means more than transfusion of plasma or blood. It entails rest, warmth, and lying in reasonable comfort.

Surgery was taken to the second group by the field surgical units or by the light sections of casualty clearing stations. The needs of many of this group demanded it. Urgent need of operation, however, embraces two shades of meaning. It implies an imperativeness, and it may or may not imply very immediate performance. Some patients—for instance, with abdominal injuries—were little shocked and not bleeding, and could go on a further two or three hours to the casualty clearing station.

To the light sections of casualty clearing stations operative work at this level presented little difficulty. They had beds suitable tents, and highly trained orderlies. They had often worked as unchanged teams. There were, however, not enough of these light sections, and separation from their main body impaired the effectiveness of the latter in no small way. Accordingly most of the surgery at this level fell to the lot of the mobile surgical teams. Their difficulties were greater, and it was interesting and gratifying to observe, as the months passed, how by the labour and ingenuity of both field ambulances and themselves the drawbacks were gradually overcome and a level close to casualty clearing station standard was attained. To the field ambulances the field surgical units owe much in their development. The former liked to have the latter attached. It meant that for the time they were more than a staging post, that they were provided with material of great clinical interest, and that their nursing orderlies received valuable education.

The early Middle East field surgical teams, the prototypes, did not carry beds. Nor do field ambulances. A stretcher is hardly the ideal resting-place for a post-operative abdominal or dyspnoeic chest patient. Many successful efforts were made in devising back-rests to fit these. Gradually, however, a few beds were "acquired" by most units and carried forwards. (The later field surgical units, instituted by the War Office, were to be given twenty beds and bedding, and another lorry for their conveyance.)

The accommodation provided by the field ambulances was mainly in the form of collapsible shelters suspended and carried out from the sides and backs of lorries on to goal-post-like steel frames. Weatherproof as these were, they were rather a cheerless, gloomy environment for those too ill to be passed on. Gradually again from the desert, in some mysterious fashion, the field ambulances acquired the trim white windowed tents known as E.P.I.Ps.

Beds and tents, so far so good. Nursing was another problem. There were no sisters at this level. The field ambulance orderly had not had the opportunities of his casualty clearing station colleague. The latter got much continuous practice. Only on occasion would a field ambulance have a surgical unit attached. The surgeon of the latter guided and helped the orderlies, but he would often be long periods in the theatre, and there were gastric suction and transfusion drip apparatus to be watched, deterioration in patients to be observed, bleeding to be detected, let alone the other multi-

farious calls of nursing. The sisters and doctors of the R.A.M.C. get much praise; the rank and file get less than their due. These orderlies were keen and industrious, and many reached high levels of intelligence and proficiency. But it stood to reason that with only occasional experience they would not achieve the standard of nursing of a casualty clearing station.

It was thus becoming evident before the end of the desert campaign that to overcome these drawbacks any advanced operating centre forward of a casualty clearing station would be best constituted by two surgical units and a transfusion unit, attached to a main dressing station. (The new system of field dressing stations was not yet here in operation.) The transfusion unit took much of the worry off the surgeons, not only by saving their time but by its officer supervising the pre-operative ward, and, in conference with the surgeon, deciding priorities. The presence of a second surgical unit meant a more regular spell of duty for each surgeon and the opportunity of more careful post-operative supervision. A further development which took place later in Italy was the institution of a pool of experienced nursing orderlies at the Corps field ambulance. These had all been a year or more with casualty clearing stations and could now be called upon by these forward detached surgical centres. The arrival of fresh field ambulances had made this desirable, since their orderlies were as yet little experienced in this type of nursing. (On occasions, when suitable accommodation was available, sisters went forward to this level.

None the less, it can be imagined that the casualty clearing station was still the better place if the wounded men could be got there safely.

Another disadvantage of the solitary forward team needs mention. The field ambulance and its team sometimes had to be up and doing before the patients it harboured were fit to be moved. Occasionally another unit such as a casualty clearing station took over the site and the patients. Otherwise a party had to be left behind to nurse them. The surgeon could not always look back. Complications might arise and no theatre was available. The ordinary arrangements, however much care was taken, were relatively primitive and cheerless. The casualty clearing stations, on the other hand, were relatively static, and by the time they had been leap-frogged several times their patients were fit to move.

The detached field surgical units did work which caught the imagination. To the other Services, laymen in these matters, the idea of a mobile surgeon who could operate upon a casualty almost at once was in military slang "just the job." The operation itself hypnotizes the layman to the exclusion of other necessary but less publicized considerations. There developed almost inevitably a tendency to try to exploit these mobile units beyond what was wise. In their laudable anxiety to help the fighting troops to the utmost, even medical minds, though not of those in the highest positions, became a little imbued with the same tendency. It is not a good thing to move these teams over-frequently, for the reasons given above. Again, it is not wise to have advanced operating centres too far forward, within ordinary range of the enemy's guns or in close proximity to the noise and tremor of our own. A mile or two can make much odds. For it is the most serious cases which are to be treated, and they have not only to be operated upon but to be held several days. It is a terrifying thing for bed-bound patients in a tent to be shelled or bombed. Weak though they may be, not all will remain bed-bound, and indwelling drip and suction tubes soon become outdwelling as the casualty takes to earth. Apart from this, the surgeon must have reasonable quiet and rest if he is to do good work. There occurred necessary and advantageous exceptions to the rule. In the early stages of invasions work had to be done within range of fire. Again, if an odd shell kept dropping into a town or village where a suitable building for a unit was available, not too much was thought of that.

#### The Specialized Units

The development of forward specialized work is one of the most interesting items in the surgical history of the campaigns. The need for mobile ophthalmic units in forward areas had long been recognized and met, and the tale of eyesight saved by this wise provision will no doubt in time be told. The other

surgical specialized units of the army are devoted to chest, maxillo-facial, neurosurgical, and orthopaedic work. Since orthopaedics in the field is essentially concerned with compound fractures, all forward surgeons must be orthopaedists up to a point. The place for the special orthopaedic teams is at a site where patients can be held for a period up to two or three months so that skeletal-traction appliances and the like need not be disturbed by premature evacuation. Their place, then, is at the base hospitals—better still, at an advanced base when such holding is possible. It usually needs time before an advanced base hospital is in a position to hold other than danger-list and some other special types of case not requiring more than four or six weeks' retention at this stage.

To provide early skilled treatment a few mobile neurosurgical units had been formed at home early in the war. At the time of el Alamein there was one of these in the Middle East. To provide the widest service it was located in Cairo. Patients could be sent there fairly quickly from the army's jumping-off point, and, with the aid of air transport, for some time in the early advance. About two months later, when the army had advanced some 800 miles, a second unit arrived and was sent forward, to be attached at first to a casualty clearing station on the lines of communication. Later, when the battle had swept well beyond Tripoli, it arrived during the formation of that advanced base. Delays of evacuation were proving a problem, so the unit was split. The advance party went to the foremost casualty clearing station which drained the line; the rear section stayed at a hospital in Tripoli. There they received the operated-upon patients, most of whom travel well, and retained the serious cases in optimum circumstances, the others going on to the Delta by air or sea. This arrangement of the split team held admirably right up into Italy, although administrative troubles supplied a hitch or two. Its success in the desert has been related. Even greater scope was forthcoming from the heavy fighting on the Trigno and Sangro in Italy in the closing weeks of 1943.

A maxillo-facial team was dispatched to Tripoli at the time the advanced base was set up, and remained there till the end of the Tunisian campaign. When Sicily was invaded, it was decided to split this team also so that severe cases there should have prompt attention and yet there would remain a section at a general hospital. The advanced section was eventually pushed forward experimentally to the same level as the ophthalmic and neurosurgical. The three, "the unholy trinity" as they were known, thereafter were kept together. They were located always at the most forward casualty clearing station which drained the whole line. This, because of the more usual narrow front, was often the foremost. The vast majority of the special casualties thus passed through the sections of these teams at an early period after wounding. By such siting the general surgeons were relieved of much worry, and the argument of how much they should or should not do was largely dispensed with. They were quite willing, indeed eager, to pass on these patients to more-trained teams so long as the latter were at hand. Previous advice, to clean up such wounds and send the patients back to an advanced base for special treatment, was unsatisfactory. Once a general surgeon, untrained in a specialty, embarks on such a cleansing he tends to do too little or too much.

The exigencies and variations of war, however, are unlikely always to allow such ready facilities, particularly if special teams are few. As circumstances permit it would seem wise to train general surgeons in the elementary technical procedures admittedly necessary. Otherwise it is unjust of specialists to deride the general surgeon's results, as is so frequently done. This is as unfair as the proposition, equally often asserted, that the specialist can do all the general surgeon's work competently.

The chief justification for an advanced maxillo-facial team was for the fractured-jaw patient to have uniform early and adequate fixation—the dental surgeon's business. Splitting of the team as it was done sent forward also a surgeon with plastic training. This was still more experimental and of doubtful value. But the surgeon concerned, admittedly at first somewhat sceptical, was in a few months able to report that he had found plenty to do. His work included submandibular

drainages, removal of foreign bodies, closure of deep layers of cheek wounds, the accurate suture of lips, the immediate replacement of displaced fractured nasal bones, zygomatic bones, and orbital margins, and the repair of torn eyelids. In many instances the patients with these injuries could not have reached an advanced base hospital till three days later.

It needs little imagination to appreciate the value of the trinity at this level, not only singly but in conjunction on the same patient.

As field ambulances had fostered field surgical units, so likewise casualty clearing stations fostered the trinity. There were sometimes difficulties of accommodation in one casualty clearing station for the extra theatres and personnel. The drawbacks were always overcome and the trinity remained undivided. It is doubtful, however, if the specialties could have worked so closely together had their teams not been split. The trinity would then have been too cumbersome for any of the foremost casualty clearing stations to accommodate in addition to the general teams.

The chest specialty was not made so advanced, although, had there been a sufficiency of chest teams, the experiment of placing a team at the same level as the trinity might have been tried. The policy with only one team "in the field," as distinct from the base, was to place the field unit with a suitable advanced general hospital. Theoretically it was at a site where it could hold patients for six weeks. In practice it could not hold them all because of the other heavy demands upon such a hospital. But it could hold the serious ones. Haemothorax and its possible infection constitute the most important complications of chest wounds. Removal of foreign bodies and the treatment of complications are better performed, if possible, with the greater facilities of a general hospital in the matters of x rays, theatres, laboratories, and nursing. What the field surgeon contributed to the chest specialty was the closing of sucking wounds, débridement of others, and aspiration of haemothoraces after 48 hours. Only occasionally was anything more indicated.

(To be concluded)

## SENSITIVITY TO LIVER EXTRACT

BY

J. G. MCSORLEY, M.B., B.Ch., B.A.O.

AND

L. S. P. DAVIDSON, B.A., M.D., F.R.C.P.

(From the Department of Medicine, University of Edinburgh)

The purpose of this communication is to stress the not uncommon occurrence of allergic reactions to intramuscular liver therapy, their alarming nature on occasion, and the practicability of desensitization.

Since Schlesinger (1930) first drew attention to the occurrence of reactions to liver therapy we have been able to find in the literature records of less than a hundred cases of allergic reactions to oral, intravenous, and intramuscular liver therapy. When the widespread use of liver extracts throughout the world is considered, such a small number of reported cases would appear to indicate that allergic reactions to liver extracts are rare. Delikat (1943) had 14 cases of sensitivity to liver therapy among 200 cases of pernicious anaemia, and records in detail three severe cases. Of 60 consecutive cases of pernicious anaemia admitted to our wards during the past five years, four (6.6%) have subsequently developed reactions after one to three years of maintenance therapy. Barfred (1942) reports 19 cases showing allergic reactions among a total of 49 treated with intramuscular liver extracts—an incidence of approximately 40%. It should be pointed out, however, that Barfred was using experimental extracts which were often neither purified nor concentrated, and hence were given in large amounts (5 to 10 c.cm.).

We have been able to find only two papers in the British literature devoted to the subject of allergic reactions to liver therapy. Andrews (1941) records one case and Delikat (1943) three cases in detail. The most significant British reference is contained in a letter to the *British Medical Journal* by Morgans (1943)—a few weeks after Delikat's article—record-

ing the only fatality ever published from a reaction to an intramuscular injection of liver extract. In 1936 Ungley, Davidson, and Wayne, in an investigation of the clinical efficacy of the original Dakin and West preparation (anahaemin), mentioned that reactions to intravenous therapy occurred in two cases.

Reactions to liver extract may be classified as primary—i.e. those occurring after the first liver injection; and secondary—i.e., those which appear for the first time after weeks, months or years of parenteral therapy.

Primary reactions are not due to acquired sensitivity, but are an immediate response of the body to the parenteral injection of foreign material. Such reactions were much more common when liver extracts were given by the intravenous route (Castle and Taylor, 1931; Murphy, 1932). The use of the intramuscular route and the purification and concentration of liver extracts have resulted almost in their complete disappearance. Disagreeable effects reported include pyrexia, collapse, shivering, vertigo, flushing, headache, and dyspnoea (Strauss and Castle, 1932; Schlumm, 1932; Strandell and Hammar, 1932).

Secondary reactions to oral, intravenous, and intramuscular liver therapy have been described. They are undoubtedly of an allergic nature. In support of this contention are the eosinophilia, the latent period between the primary injection and the onset of symptoms, the clinical features, including bronchospasm and the characteristic skin reactions, and the response to adrenaline. Sensitivity can be passively transferred to a normal individual from the sensitive individual by the Prausnitz-Küstner technique (Grün, 1934; Lasch, 1936; Crieep, 1938; Pache, 1939; Jones, 1939; and ourselves in 2 cases). The sensitivity has been shown to be specific to the organ from which the extract has been prepared rather than for the species of animal concerned (Crieep, 1938; Pache, 1939; Jones, 1939; Scarlett and Macnab, 1942).

During the past ten years one of us has had referred to him approximately 40 patients with reactions to parenteral liver therapy, 21 of whom have been investigated during the last two years. Of these cases 15 were so severe that they were admitted to hospital for investigation and desensitization.

A study of the literature shows that sensitivity has occurred to all the leading brands of liver extract. On the continent of Europe, campolon in Germany and pernaemon in the Netherlands appear to be often incriminated, while in America reticulogen and Lederle extracts are those chiefly mentioned. In our experience anahaemin and campolon are the commonest offending extracts, but we have also had cases sensitive to other British extracts and to Continental and American products. The frequency with which reactions are reported to such highly purified extracts as reticulogen and anahaemin indicates clearly that the causation of the reactions does not correspond to the degree of purification and concentration, but rather to the chances of sensitivity occurring from extracts which enjoy the greatest popularity in the various countries.

When such sensitivity is established to a particular liver extract, injections of a different extract may be given in some cases without any reactions. Thus on occasion we have had patients sensitive to anahaemin, or campolon who tolerated reticulogen well. Such patients, however, tended to become sensitive to reticulogen in a period of weeks or months. In general, however, our experience suggests that if a patient shows marked reactions to one liver extract, sensitivity will extend to all liver extracts.

The reaction generally occurs within 5 to 30 minutes after injection. In many reported cases, and 9 out of 19 of our cases investigated during the past two years, there have been periods of interruption of therapy lasting in some instances for several months, with the reactions appearing shortly after the resumption of treatment but not after the first injection of the new course of treatment. Another important feature is that once the reactions have appeared they usually increase in severity after successive injections.

### Types of Reaction

A study of the literature reveals that almost every type of allergic reaction has been observed in cases sensitive to liver therapy. The commonest reactions, in our experience, are

flushing, tachycardia, erythema, and localized urticaria. Reactions vary much in severity, from the mild features mentioned above to generalized urticaria, severe bronchospasm, vomiting, rigor, hyperpyrexia, severe nasal and ocular discharges, substernal pain, collapse, and angioneurotic oedema. One or more of these manifestations were present in each of our cases. Allergic manifestations not observed by us but reported by other workers include swelling of the lymph nodes, hemiplegia (Kaufman *et al.*, 1943), and repeated uterine haemorrhages (Gardner, 1938).<sup>\*</sup> Sensitivity may reach such an extreme degree that even the injection of 0.1 c.cm. of liver extract given intradermally for the purpose of making a skin test has brought about severe flushing, bronchospasm, and tachycardia in one of our cases.

#### Skin Tests

Opinion regarding the value of skin tests for assessing the presence and degree of sensitivity in allergic diseases is sharply divided. No less an authority than Raekemann (1943), in a paper dealing with the problems of allergy, concludes that "skin tests have lost some of their glamour." It is well recognized that a patient may give a positive skin reaction to pollen or to tuberculin and yet not be suffering from hay-fever or active tuberculosis. Similarly, patients who have been receiving liver extract are not infrequently positive to a skin test and yet show no reactions to parenteral liver therapy. This was found by us in 16 of 52 cases of pernicious anaemia. Conversely, it is known that skin tests may be negative in allergic conditions, and yet severe allergic reactions may occur to parenteral injection of the specific allergen. Thus Bullowa (1937) reported 8 fatal cases of anaphylaxis to antipneumococcal serum, in all of which previous skin tests for sensitivity were negative. In two of our cases with extremely severe allergic reactions skin tests were negative, later becoming positive in one case when urticaria developed as an additional feature to bronchospasm. Despite these limitations, our experience suggests that it is worth while doing skin tests, since we have found in the majority of cases that the degree of the skin reaction bears some relation to the severity of general sensitization and the reactions which result. Moreover, if general reactions follow the skin test it may be concluded that the patient is extremely sensitive.

#### Technique of Skin Tests

We inject intradermally 0.05 c.cm. of undiluted liver extract into the volar surface of the forearm just below the crease of the elbow-joint, with a saline control at the same level. We accept as a positive reaction a wheal of 15 mm. or more, developing in 15 to 30 minutes. Pseudopodial extensions from the wheal occur in practically all patients who are very sensitive. The size of the surrounding red areola is of little significance. Pache (1939) reported positive intradermal reactions to liver extract in a dilution of 1 in 1,000,000. As severe generalized reactions may occur to the skin-test dose of 0.05 c.cm., adrenaline should always be at hand in case of emergency.

#### Treatment

We have arbitrarily divided sensitive patients into two classes for treatment: (1) those with mild symptoms, and (2) those with severe constitutional reactions. It is permissible in mild cases to attempt to control the reactions by injecting three minims of 1 in 1,000 adrenaline hydrochloride concurrently with the liver preparation. In some cases this may be sufficient without any alterations or additions to treatment. In other cases satisfactory results may be obtained by reducing the quantity injected to one-half or one-quarter of the dose which produced a reaction and decreasing the periods between injections by a quarter or a half. Adrenaline may be given at the same time. After a few weeks on this treatment the dosage and the intervals between injections can be gradually increased to the desired maintenance levels.

The following measures have been recommended as adjuvants for the reduction of sensitivity, but proof of their value is wanting: (1) calcium orally and parenterally (Lasch, 1936; Gigante, 1939); (2) injections of parathyroid to raise the blood calcium (Lasch, 1936); (3) histamine in gradually increasing

doses to produce histamine refractoriness (Corelli, 1935); (4) histaminase, a supposed inactivator of histamine (Taylor and Hilger, 1941). The latter workers claimed that histaminase, given orally, not only prevented reactions but also reduced or abolished positive skin sensitivity, precipitin reactions, and passive transference of sensitivity. When the histaminase was discontinued, reactions and positive sensitivity to skin tests recurred. We have been unable to obtain histaminase to test the accuracy of these claims. It should be noted that Raekemann (1943), in a discussion of the value of histaminase in preventing allergic manifestations in general, states that its efficacy is doubtful.

Barfred (1942) claimed that the preparation of liver extract with butyl alcohol removed a considerable part of the factor causing allergic reactions. Accordingly we asked British Drug Houses Ltd. to supply us with a sample of anahaemin which had been extracted with butyl alcohol. The material was tested on two cases sensitive to anahaemin, and, in both, reactions occurred of a degree and a type similar to those produced by the standard anahaemin. In addition, when the butyl alcohol was evaporated and the residue dissolved in water its intradermal injection failed to give positive skin reactions in the two cases referred to above. Accordingly we are unable to confirm Barfred's claims.

#### Severe Cases

Patients who are suffering from dangerous allergic reactions must either replace parenteral liver therapy by oral ingestion of whole liver, liver extract, or hog-stomach preparations, or submit to desensitization. Desensitization has been recommended and carried out by Grün (1934), Krantz (1938), and Delikat (1943). Increasing doses of the liver extract were given subcutaneously or intramuscularly at intervals of days or weeks. The method which we have found satisfactory in 17 severe cases, including two desensitized by Dr L. J. Davis, Lecturer in the Department of Medicine, is as follows:

The degree of sensitivity is assessed by the history of the severity of the generalized reactions and by the response of the skin and the patient to an intradermal test of 0.05 c.cm. of the liver extract to be used. If any generalized reaction occurs to this test, desensitization should be started with a smaller quantity of liver extract, such as 0.01 c.cm. In the great majority of cases 0.05 c.cm. was found to be a suitable initial dose. With the initial and all subsequent injections, 0.2 c.cm. of adrenaline hydrochloride (1 in 1,000) is given. The dose of liver extract is doubled every half-hour and the route of the injection is changed from the intradermal to the subcutaneous when the 0.4-c.cm. dose of extract has been reached, and to the intramuscular route at the 1-c.cm. dose. It is our experience that if a reaction is going to occur during desensitization it generally follows the 1-c.cm. dose. In this event the same dose is repeated in half an hour, and if no reaction occurs the dose is increased to 1.5 c.cm. and finally to 2 c.cm. of extract at half-hourly intervals. In the majority of cases desensitization is secured in three to five hours. Thereafter it is advisable to repeat the final dose (2 c.cm.) daily for three days without the addition of adrenaline. Weekly doses of 2 c.cm. are now given for six weeks, and finally maintenance therapy is continued by a single injection once every two, three, or four weeks. We advocate the daily and weekly injections mentioned above because we have found that there is a tendency for sensitivity to recur if the interval between the initial course of desensitization and the next injection is delayed for two weeks or longer. Although Kaufman *et al.* (1943) advise that the intervals between injections for maintenance treatment should not exceed one week, since otherwise sensitivity will recur, this has not been our experience, as we have at the present time 14 patients who have been desensitized and who have maintained a normal blood level for one to two years without a recurrence of sensitivity on an intramuscular injection of 2 c.cm. of anahaemin monthly. Attention has already been drawn to the frequency with which a history was obtained of sensitization occurring subsequent to breaks in the continuity of treatment. Accordingly it is essential that intervals between injections should on no account exceed four weeks.

#### Conclusion

We would advocate desensitization for patients allergic to liver extract rather than the alteration of treatment to the oral ingestion of liver or hog-stomach preparations, since it is generally agreed that parenteral therapy is cheaper and more effective than oral therapy. Desensitization is, however, a potentially dangerous procedure unless carried out under strict supervision by someone experienced in the danger of anaphy-

<sup>\*</sup> Since the preparation of this paper a case showing uterine bleeding as a manifestation of allergy to liver extracts has come under our care.

active reactions. This danger is greatly increased if the patient is seriously debilitated or is suffering from cardiovascular disease. A potent solution of adrenaline hydrochloride and a sterile syringe must always be at hand; and 0.5 c.cm. should be given immediately any signs of an allergic reaction occur.

### Summary

The nature and frequency of reactions to parenteral liver therapy and the significance and technique of skin tests for sensitivity are discussed.

The successful desensitization of 15 cases with severe reactions is reported, with a description of the method employed.

We wish to express our thanks to those of our colleagues on the staff of the Royal Infirmary, Edinburgh, who have permitted us to investigate cases of sensitivity under their charge. One of us (J. G. M.) was in receipt of a Bursary in Medicine from the National University of Ireland during part of this investigation.

## EXPERIMENTAL TRAUMATIC SHOCK

BY

J. CHARNLEY, M.B., F.R.C.S.

Major, R.A.M.C.

The aetiology of traumatic shock still eludes final proof. All are agreed that a reduction of blood volume underlies the state of shock, but the mechanism whereby this reduction occurs is still obscure.

Traumatic shock has been investigated by clinicians and experimentalists, and many important facts have been established. There is, however, a fatal tendency to mix indiscriminately the facts of clinical shock with the facts of experimental shock, and a tendency to mix deductions from one type of experimental shock with shock produced by quite unrelated means. As a result of loose inference the problem of shock is to-day more difficult than it has ever been, and as much time must be spent in "debunking" the literature as in tackling the facts of the problem itself. Before the gaps between the various aspects and manifestations of shock can be bridged by a single theory the truth of each aspect must be firmly established. It is the purpose of this paper to concentrate exclusively on experimental traumatic shock produced by mechanical trauma to a limb.

Despite the fact that experimental traumatic shock might be considered a threadbare field for research, there is no unanimous answer to the question, "Why does an animal under anaesthesia pass into shock when severe mechanical trauma is applied to the limb muscles?" This problem is purposely kept within narrow and artificial limits. Until the complete answer is known it is fatal to make analogies with the causes of shock after burns, of surgical shock in the presence of superadded disease, or of the complex mixture of oligæmic, neurogenic, psychogenic, and metabolic factors which contribute to the state of shock in the wounded soldier.

An attempt is made here to present an old experiment in a new light, and to emphasize the need to regard this artificial

problem as one which should be capable of complete experimental proof; then, and then only, can it be viewed in relation to the problem of shock in general.

### The History of Traumatic Shock

Traumatic shock first aroused interest during the war of 1914-18 by the fact that it often supervened some time after the patient was wounded and after a mysterious latent interval during which he appeared quite normal. It was the nature of this latent interval which focused attention on shock. It was this which gave rise to the clinical entities described as "primary" and "secondary" shock.

By what was no more than a remarkable coincidence physiologists, notably Dale and Laidlaw (1918) and Dale and Richards (1918), were interested at this time in the pharmacological reactions of the comparatively new substance histamine, which seemed likely to open up new vistas in physiology. In a hurried piece of research undertaken during the war, when a solution was urgently needed, Cannon and Bayliss (1919) appeared to establish as a fact that so-called "secondary" shock was due to the action of a tissue toxin akin to histamine.

About ten years later Blalock (1930, 1934) started to publish the results of further investigations on the Cannon-Bayliss experiment, undertaken with a degree of patience probably unequalled in the history of experimental surgery. He failed entirely to find any toxic cause for shock, and produced many reasons explaining the death of the Cannon-Bayliss animal as the result of local fluid loss at the site of trauma. But many of the forms of shock encountered in clinical practice—i.e., after surgical operations, after head injuries, burns, etc.—seemed so obviously unrelated to haemorrhage that there was a tendency to reject Blalock's theories even for the conditions of his own experiments. This refusal to believe led to a determination to find some other explanation with a dangerous over-elaboration of experimental technique.

As regards the toxæmic theory of shock few new facts have emerged. The capillary phenomena following toxæmia produced by the introduction of crushed muscle into the peritoneum have been extensively studied by Moon (1938) and his collaborators, though it is doubtful whether this bears any relation to the conditions of the original Cannon-Bayliss experiment. Practically all recent variations of this latter classical experiment—notably the dialysis experiment of O'Shaughnessy and Slome—have failed to reveal any toxic substance in the blood stream.

There remained only the nervous pathway for secondary shock, and O'Shaughnessy and Slome (1935) believed that they were able to demonstrate such a condition in the absence of blood loss and toxæmia. It is to be noted in this connexion that at the time when Cannon and Bayliss did their original experiment neurogenic factors were in the public mind one of the most likely causes of delayed shock. But these workers, and later Blalock in a more extensive research, were entirely satisfied that this very obvious source was not a cause of experimental traumatic shock. It was only after excluding this possibility that there was any justification for assuming a toxic theory of shock. The experiments of O'Shaughnessy and Slome were extremely elaborate, and there could be but little surprise that shock resulted.

Finally, clinical experience now casts doubt upon the existence of "secondary" shock as a clear-cut entity. Modern battle and air-raid casualties tend to be shocked progressively from the time of reception of the wound. It is the exception rather than the rule for a patient to appear initially quite fit and later to pass into a state of shock for no apparent reason. The disappearance of the mysterious latent interval removes the original condition for which toxic theories were first invoked. The latent interval seen in 1914-18 might have been due to exposure to wet and cold for many hours after wounding—a state of affairs not commonly seen in this war, but one often commented on in the Special Reports of the Medical Research Council of 1917-18.

Cannon and Bayliss (1919) established as a definite fact that shock did not result if the femoral artery and vein were ligated before applying trauma to the thigh. This fact has never been questioned since, and Blalock carried the experiment a little

further by showing that shock did not result even if the artery alone were tied, the vein being left patent. He explained this absence of shock on the grounds that the local blood loss was reduced by the ligature, and felt that there was here strong evidence against the toxic theory.

### The Present Experiment

It is my purpose to attempt to show that this simple experiment of femoral artery ligation is capable of a very much wider interpretation than has generally been ascribed to it. The research pursues the following scheme: (1) control series without ligation of the vessels; (2) effects of ligation of the femoral artery before trauma; (3) investigation of the collateral circulation after ligation.

#### Series 1

##### Trauma without Ligation of Vessels; 25 Cat Experiments

The anaesthetic was intravenous chloralose 0.09 g. per kg of body weight, after preliminary ether induction. All animals were kept at 39° C. on an electrically heated table and controlled by rectal thermometer. A kymographic record of carotid blood pressure was made, using saturated sodium bicarbonate solution in the cannula. Trauma was applied to the thigh with a 5-lb padded mallet, and a standard number of 50 blows were applied and the femur fractured in all cases. Shock level of blood pressure was taken as 70 mm. Hg. and was reached in times varying from 20 minutes to 6 hours after trauma. Shock did not develop in 3 of these cases even after 6 hours. It was invariably noticed that the crushed thigh was visibly and palpably swollen even before the end of the trauma was reached, and this speed of the initial swelling left absolutely no doubt that a brisk internal haemorrhage into the muscle planes was the immediate sequel to trauma under these conditions.

At the conclusion of the experiment the animal was killed, if it had not already succumbed to the shock, and the increase in weight of the traumatized limb was estimated as described by Blalock—i.e., the tail was removed, the trunk severed at the level of the lowest lumbar vertebra, and the pelvis sectioned through the midline. The weights of the two hind quarters thus separated could then be compared. Control attempts to divide untraumatized hind quarters showed that this manoeuvre could not be done with an error of less than 10 g., but even this inaccuracy did not invalidate general comparisons. The original blood volume of the animal was deduced from the figures quoted by Holt and MacDonald (1934) as being 5.75% of the body weight in the cat. The increase in limb weight was thus converted into percentage loss of total blood volume.

In these 25 experiments the proportion of the total blood volume lost into the traumatized thigh averaged 37%. This agreed closely with the 35% found by Holt and MacDonald in the same experiment.

#### Series 2

##### Trauma after Ligation of the Femoral Artery; 10 Cats

Anaesthesia as before. The carotid blood pressure was not recorded in this series until the conclusion of the experiment. The femoral artery was tied through a small incision in the groin. A similar amount of trauma was then applied to the thigh—i.e., 50 blows with the same mallet, and the femur fractured in all cases. The absence of rapid swelling of the thigh after trauma in these cases was very noticeable.

Clinical examination revealed no evidence of the onset of shock, and after 6 hours the carotid blood pressure was recorded by tying in a cannula and connecting to the kymograph. The pressures recorded after 6 hours were: 140, 120, 160, 95, 160, 100, 100, 90, 100, 100 mm. Hg. The three high pressures might have been due to the pressor effects of small additional doses of chloralose which had to be given in some cases towards the end of the experiment. In no case was shock level even approached. The average loss of total blood volume into the thigh in this series was 19%.

#### Series 3

##### Examination of Collateral Circulation after Ligation of Femoral Artery and Trauma to Limb; 4 Cats

(a) After 6 hours 4 of the preceding animals traumatized after ligation of the femoral artery showed the following carotid blood pressures: 120, 140, 100, 100 mm. Hg. A second arterial cannula was now taken and tied into the femoral artery distal to the previously applied ligature, and directed with its lumen open towards the foot. The cannula thus recorded the pressure of the anastomotic circulation existing in the femoral artery distal to the ligature. This arrangement is shown diagrammatically in the accompanying illustration. The pressures recorded in this second cannula were

respectively 40, 50, 40, 35 mm. Hg. These pressures are thus roughly one-third of the respective systemic arterial pressures. Such anastomotic pressures should be capable of maintaining a considerable anastomotic circulation through the limb.

(b) In the same 4 cats the great saphenous veins were exposed in both legs just below the knees. Into the normal limb an intravenous injection of 0.1 c.c.m. of a weak solution of histamine was given. The usual transient fall of arterial pressure was recorded on the kymographic tracing of the carotid blood pressure. This fall started 10 to 15 seconds after the injection was made. When the carotid blood pressure was restored to normal level 0.1 c.c.m. of a solution of histamine was injected at the same level into the saphenous vein on the traumatized side. It was found that the arterial depression resulted from 30 to 40 seconds after the injection. This volume of solution—0.1 c.c.m.—could not have reached the general circulation by virtue of its bulk, and must have been washed in by the venous return from the limb resulting from the anastomotic circulation. Ligation of the femoral artery delayed this return from about 15 seconds to about 40 seconds.

Diagram showing the method adopted in Series 3

### Discussion

In making deductions from this femoral ligation experiment, four factors deserve special attention:

1. That ligation of the femoral artery prevents the onset of shock on subsequent trauma to the limb.
2. That local blood loss is reduced from about 35% of the total blood volume to about 19%.
3. That rough qualitative tests indicate the existence of an active collateral circulation after trauma to the limb in the presence of the femoral ligation.
4. That the rate of swelling of the traumatized limb is much slower in the presence of a ligation on the femoral artery.

The absence of shock after trauma in the presence of a ligation on the femoral artery could be explained according to the current theories of shock in three ways, thus:

1. By the reduction of local fluid loss (oligaemic theory).
2. By a reduction of venous return from the limb (toxaemic theory).
3. By anaemia affecting sensory-nerve endings (neurogenic theory).

The crux of the femoral ligation experiment lies in the explanation of how the ligation can reduce the amount of local fluid loss and yet leave an effective collateral circulation. These two matters might at first sight appear incompatible; indeed, it could be argued that, though observations might indicate an active collateral circulation, the fact that local haemorrhage is reduced after the ligation must prove that these observations were fallacious.

There is, however, a simple explanation for this apparent paradox. When a limb is heavily traumatized without a ligation on the main artery the initial swelling of the limb proceeds at such a visible and palpable rate as to leave no doubt that a great part of this initial swelling is due to a rapid extravasation of blood under high arterial tension. Now, the

amount of arterial blood lost into the tissues during and immediately after the trauma depends on (a) the height of the arterial pressure in the ruptured vessel, and (b) the time elapsing before the haemostatic factors of arterial retraction and coagulation stem the initial extravasation.

After ligation of the main artery, and though the collateral circulation is quite effective for ordinary purposes of nutrition, etc., trauma to the limb results in extravasation of blood at only one-third of full arterial pressure (for this was the pressure discovered by direct measurement in the preceding experiments). During the time interval before haemostatic mechanisms come into action there is thus a smaller effusion of blood into the traumatized part. This, then, explains how the femoral ligature can reduce local blood loss after trauma without necessarily implying a defective collateral circulation through the limb.

As regards the toxæmic theory of shock, these observations agree with the deductions of Blalock—that shock does not result if all venous channels are open to the systemic circulation, provided that local blood loss into the limb is restricted.

These results are also consistent with those of all observers since the original Cannon-Bayliss experiment who have failed to find shock resulting from sensory-nerve stimulation under experimental conditions. How do these observations compare with those of O'Shaughnessy and Slome? It will be recalled that these workers severed all vascular connexions to the hind limb of an animal, A, and kept this limb alive by cross-circulation from a second animal, B. (It is interesting to note in parenthesis that to isolate this limb from the general circulation needed an extremely extensive multiple ligation of all collateral channels.) On traumatizing the perfused limb of animal A they were able to produce late shock in the systemic circulation of animal B. The limb was in connexion with the systemic circulation by only nervous channels. The nature of this shock must, however, be regarded with suspicion, as the necropsy appearances of the tissues which they describe are in no way consistent with their own excellent description of the typical appearances in traumatic shock. The great criticism of this elaborate experiment is that incidental trauma (which is extensive) is biased towards the production of the desired result—i.e., to produce shock. Compare this with the femoral ligature experiment, in which experimental factors are biased against the desired result—i.e., for a positive result the animal must *not* pass into shock during an experiment which is in itself very likely to result in shock. This is a very stringent experimental criterion.

In interpreting the results of the femoral ligature experiment it is possible to go a step further. There is always the theoretical possibility that traumatic shock might not be the result of only one factor, but of the combined action of several factors. Most experiments on traumatic shock have been ingeniously designed to study the action of only one factor at a time. In the experiment of femoral ligation described here all factors are capable of acting at one and the same time. Thus after losing 19% of its blood volume and being open to neurogenic and toxic shock channels, the blood pressure was still high after six hours.

### Conclusions

In the cat, under chloralose anaesthesia and for periods up to six hours after severe trauma to a limb, no evidence could be found for the existence of any shock-producing factors, or combination of factors, other than that of local fluid loss.

This work was done in the physiological laboratories of King's College, London, in 1939, through the kindness of Prof. R. J. S. McDowall, to whom I am deeply indebted. The costs of the research were defrayed by a grant from the Medical Research Council.

## DICOUMARIN IN THE TREATMENT OF PUERPERAL THROMBOSIS

BY

ALBERT DAVIS, M.D., Ch.M., F.R.C.S.

Consultant Obstetric Surgeon, London County Council

AND

MARGARET PORTER, B.Sc.

Biochemist, Dulwich Hospital (L.C.C.)

3:3-methylene-bis-(4-hydroxy-coumarin)—“dicoumarin”—is the anticoagulant principle of spoiled sweet clover, ingestion of which causes haemorrhagic disease in cattle. Since its introduction by Link in 1941 the drug has been employed experimentally in a variety of conditions, notably post-operative thrombosis, and the present paper embodies the results of an investigation into its possible value in obstetrics. In all, 43 cases of post-partum thrombosis were treated. They were of every degree of severity, from small saphenous lesions to bilateral femoral blockage; but, in view of their common origin, the general action of the drug, and the homogeneity of its results, they are here grouped together without further classification.

### Properties

Dicoumarin is a powerful anticoagulant, the action taking place at the prothrombin level. Given by mouth the drug takes approximately 24 hours to act, but with continued administration the result is a steady rise in the clotting time, the effect lasting for several days after the dicoumarin is discontinued. It greatly reduces the incidence and degree of thrombus formation after the intravenous injection of ethanolamine in dogs (Richard and Cortell, 1942), and is apparently similarly effective in preventing post-operative thrombophlebitis and pulmonary embolism in man (Baker, Allen, and Waugh, 1943). It also appears to limit the extension of an already established thrombosis and to produce symptomatic improvement in cases of thrombo-angiitis obliterans (Bingham *et al.*, 1943). Most observers state that although dicoumarin is an anti-prothrombin its effects are not antagonized by vitamin K. Our own results, however, show that when both preparations are administered simultaneously the coagulation-time curve rises more slowly and less steeply than when dicoumarin is given alone. This confirms Townshend and Mills's (1942) clinical observation that, while blood transfusion failed to produce any perceptible decrease in the prolonged prothrombin time of a case in which dicoumarin had induced haemorrhage, a second transfusion plus vitamin K therapy resulted in an immediate drop of the prothrombin and coagulation times to normal levels, and these normal values were maintained. It would indeed be surprising if this view of the antagonism of the two drugs were incorrect; for, theoretically, vitamin K is primarily concerned with the physiological elaboration of prothrombin in the liver. One must assume that its reported impotence in some cases of established dicoumarin haemorrhage is due to secondary changes produced by the anaemia.

Dicoumarin differs from heparin in method of administration, speed of initial response, and mode of action. The latter must be given by intravenous injection; but its action is instantaneous, the effect being produced by inhibition of platelet agglutination. Otherwise the clinical effects are similar, except that heparin haemorrhage reacts well to simple blood transfusion.

### Dosage

Experimental overdosage with dicoumarin in animals produces multiple haemorrhages. In fatal cases there is central necrosis of the liver (Rose, Harris, and Chen, 1942), with widespread haemorrhage indiscriminately throughout the body. There is a considerable difference in tolerance between various species of animals, and also among individuals of the same species. This latter is of much significance, for it applies equally to man, and calls for extreme care in therapeutic administration; in fact, few of the earlier clinical reports are without a description of one or more cases of idiosyncrasy. The optimum dose is that which will reduce prothrombin to 30% of normal (Davidson and MacDonald, 1943), and this has been calculated at 200–300 mg. a day. We have taken the

higher figure, given in three separate eight-hourly doses, and as there have been no untoward results in any of our cases this dosage may be taken as reasonably safe. Published results, however, show that the margin of safety is a narrow one, apart from the possibility of idiosyncrasy, and it is essential to control the treatment by daily estimation of the prothrombin, bleeding, or clotting time. The first is the most accurate, but in our cases of already established thrombosis we have found it adequate to rely on the other two. The curves obtained parallel control prothrombin-time curves almost exactly, and their calculation is consequently easier for routine ward work.

The blood reaction to dicoumarin given in the dosage suggested is variable, but as a rule there is an average daily rise in the coagulation time of one minute, beginning 24 hours or more after the first dose. This is independent of the initial normal clotting time, which itself varies in different patients and in the same patient at different times. The time increases more or less steadily for several days, after which it remains stationary or may even be reduced, in spite of the continued ingestion of dicoumarin. The effect persists for two or three days after the drug is stopped, and the coagulation rate is usually back to normal in a fortnight. We have, however, met two striking exceptions in which the clotting time remained considerably higher than the initial normal for several months. This suggests the need for extreme care in prescribing dicoumarin for patients who have been treated with it before.

### Results

The cases varied so widely in severity that it was impossible to find an exact parallel series for purposes of control, but comparison with the same number of untreated cases showed a marked improvement after dicoumarin. There were slight but definite amelioration of pain, a fairly rapid diminution of the oedema, and a shortened average stay in hospital—19 as against 28 days.

In addition the incidence of pulmonary embolism was lowered from 9 to 4%, and in only one case was this of any degree of severity. The drug was well tolerated, and there were no untoward complications and no suggestion of spontaneous haemorrhage in any of the cases.

### Conclusions

There is no doubt that dicoumarin is of value in the particular type of patient we have investigated, and in these cases of established thrombosis it would appear to be fairly safe. The freedom from haemorrhagic complications may be due to the normal increase in the coagulability of the blood during the puerperium; but whatever the factor concerned it is of significance, for ours is the only considerable series which does not contain at least one instance of dangerous bleeding, and that in spite of a fairly high dosage. But the fact that other observers have reported accidents of a serious nature so frequently in the treatment of similar conditions must necessarily modify final judgment, and there is no doubt that the drug needs extremely careful handling. We believe, however, that the results obtained justify its employment, always provided that the haematological effects are stringently controlled by daily prothrombin or coagulation-rate estimations by a skilled laboratory technician.

We are indebted to Messrs. Organon Ltd. for generous supplies of dicoumarin and to Dr. A. N. Macbeth and Mr. J. Foley for their interest and co-operation.

R. M. Dowdeswell (*E. Afr. med. J.*, 1943, **20**, 376) examined the Widal reaction in 183 cases of typhoid fever and came to the following conclusions: (1) The rise of titre from 1 in 50 to 1 in 1,000 occurred on an average in nine to ten days; (2) the agglutinins often do not appear until after the twelfth day and may be delayed until about the twentieth day; (3) the histories of the duration of illness before admission in most cases appear to give too short a period, so that those with the later rise in agglutinins are relatively more significant.

## EFFECT OF NICOTINIC ACID ON POST-OPERATIVE VOMITING

BY

WILLIAM W. MUSHIN, M.B., B.S., D.A.

AND

HELEN M. WOOD, M.B., Ch.B., B.Sc., D.A.

(From the Nuffield Department of Anaesthetics, Oxford)

The cause and prevention of post-anaesthetic nausea and vomiting are still as tantalizing and baffling a problem to us as they were to Hewitt (1893), whose words—"unfortunately our knowledge is very scanty, far scantier than it should be upon such a subject"—still apply to-day. We do know, however, some of the factors which are concerned in the production of this disagreeable feature of the recovery period. To mention but a few: a liability to vomit (e.g., travel sickness), the site of operation and the dexterity of the surgeon, the anaesthetic agent and how it is administered, and in some cases morphine, which cannot be excluded as a causal factor.

The nausea and vomiting which are a prominent feature of pellagra (Sydenstricker *et al.*, 1938), and that which occurs during sulphonamide (McGinty *et al.*, 1939) and radiation (Graham, 1939) therapy, are markedly relieved by nicotinic acid. A pilot experiment was planned to study the effect which this substance has on post-operative sickness.

Nicotinic acid is the precursor of the pellagra-preventing (P-P) factor of the vitamin B<sub>3</sub> group, and is the active biological group in the coenzymes I and II. It is concerned in the promotion of cell oxidation and the efficient metabolism of the cells of the gastro-intestinal tract. It has been shown that its administration increases the motility of the stomach and intestines (Crandall *et al.*, 1939).

The cases in this experiment were divided in rotation into the following three groups:—Group A: Pre-operative and post-operative—nicotinic acid 50 mg. two-hourly by mouth for two days before operation, and after operation as in Group B. Group B: Post-operative only—nicotinic acid 50 mg. two-hourly by mouth as soon as conscious, and this routine continued until nausea and vomiting ceased. Group C: Control group.

Premedication consisted of morphine gr. 1/6 and atropine gr. 1/100. The patients were anaesthetized as follows. A small dose of pentothal (0.2 to 0.3 g.) was given to produce unconsciousness, and this was followed by ethyl chloride, and then ether and air from an Oxford vaporizer. The anaesthetics were all administered by the same anaesthetist. In the recovery period morphine was given if the patient was in pain or was restless. The operations were routine hospital lists, and if any bias was shown in their selection it was in the direction of abdominal operations. None of the operations were emergencies.

It is difficult to assess the disability of a patient due to nausea or vomiting. We felt that, rough measure though it might seem, an accurate impression is conveyed in terms of bouts of vomiting.

TABLE I

	Nicotinic Acid	Total	Did not vomit	1 to 3 Bouts of Vomiting	Over 4 Bouts of Vomiting
Group A	Pre- and post-operative administration (750-900 mg. per patient)	29	10	11	8
Group B	Post-operative administration only (300-500 mg. per patient)	30	7	15	8
Group C	Control	30	6	15	9
	Totals	89	23	41	25

On the basis of these figures the  $\chi^2$  test shows the difference due to nicotinic acid to be statistically insignificant.

Table II is a rearrangement and simplification of Table I to show the difference between those to whom nicotinic acid was given and the control group.

The  $\chi^2$  test (with Yates's correction) shows no significant difference due to nicotinic acid. However, in those who had been given nicotinic acid there is a slight trend in the direction

of no vomiting at all, and, in those who did vomit, towards a reduction in incidence of post-operative vomiting.

TABLE II

Treatment	Did not Vomit Post-operatively	Vomited Post-operatively	Total
Nicotinic acid ..	17 (28.8%)	42 (71.2%)	59
Control ..	6 (20%)	24 (80%)	30
Total ..	23	66	89

### Summary

The effect of nicotinic acid on post-operative vomiting was studied in two groups of patients. In one group it was given both pre-operatively and post-operatively, and in the other as post-operative treatment alone.

The doses were 50 mg. two-hourly.

A control series was studied.

In all three groups as many factors as possible were kept constant.

No statistically significant effect on the incidence of post-operative vomiting was observed as a result of administering nicotinic acid.

We wish to thank Stuart Cowan, D.Sc., for his help and advice.

## Medical Memoranda

### A Case of Generalized Vaccinia treated by Convalescent Vaccinia Serum

The following account will be of some interest as the administration of convalescent vaccinia serum for the treatment of generalized vaccinia has not been previously recorded.

#### CASE RECORD

A female infant aged 6 months was vaccinated on Aug. 27, 1943. Government lymph was used, and subsequently the Director of the Government Lymph Establishment reported that 23 other infants had been vaccinated with the same batch of lymph and no complaint of untoward results had been received by him. One insertion was made. By the time of inspection, a week later, a single small vesicle had developed and the vaccinia seemed to be running a normal course, but 10 days after vaccination the site became inflamed and indurated, vesicles appeared on the head and thorax, and the eruption then became general. The child was feverish, she became lethargic, and her condition deteriorated, and on Sept. 11 the local medical officer of health, having been called in to see the case, made arrangements with one of us (G. C.) for her immediate admission to the Poole Infectious Diseases Hospital at Alderney. He was advised to report the occurrence of generalized vaccinia and the gravity of the patient's condition to the Ministry. He did so by telephone, and to the medical officer (A. A. J.) who received the message the circumstances seemed suitable for a trial of convalescent vaccinia serum as suggested by Gordon (1941). A stock of this type of serum donated by successfully vaccinated healthy young adults about one month after the performance of vaccination has been placed by the Director-General of Army Medical Services at the disposal of the Ministry for use in civilian cases of post-vaccinal encephalitis. It is stored at the Government Lymph Establishment, and from there dried serum and a quantity of pyrogen-free water sufficient as a solvent to make 20 c.cm. of the serum were dispatched to Poole by rail.

On admission to hospital the child was in a toxic condition and appeared to be dangerously ill. She was pale, limp, and lethargic, and was roused with difficulty. She did not cry except when the injections were given, and then only half-heartedly. A slight cough was present and the stools were green. There was a sero-purulent conjunctivitis and the right eye was almost closed, the eyelids—particularly the right upper, on which there was a septic pustule—being oedematous. Twitching of the right side of the body was noticed. The temperature was 100°. On the trunk, limbs, face, and scalp there was a pustular rash resembling in character that of smallpox, but more profuse on the scalp than elsewhere. The vesicles and pustules were about a quarter of an inch in diameter. An area approximately one and a half inches in diameter centring on the vaccination site was inflamed and indurated, and the site

itself was pustular and exuding sero-pus freely. That night 3 c.cm. of the serum—the dose regarded as appropriate to the age of the patient—was injected intramuscularly. The temperature fell to sub-normal during the night and the child appeared less toxic, but next day (Sept. 12) the temperature rose to 101.4°. The rash appeared to be drying up on the trunk, but on the head and in the folds of the neck was still moist; the eyes had not ceased discharging, but were less oedematous. On that evening 4 c.cm. of serum was given intramuscularly. The next morning the temperature was 102°, but in the afternoon a change was evident: the temperature became normal, the lethargy disappeared, and by evening the child appeared to be better. That night she slept well, and by the morning of Sept. 14 she looked bright and normal. It was noticed that the pustules were drying up and crusting; and that the reaction round the vaccination site was subsiding. The temperature remained normal during the rest of her stay in hospital; the rash, however, being septic, was slow in healing, but by the end of October all the lesions had completely healed. Faint scarring was left on the face and scalp. The general condition of the child on discharge from hospital was excellent.

### COMMENT

The presence of encephalitis has been considered. The chance of the concurrence of such rare conditions as post-vaccinal encephalitis and generalized vaccinia is remote, but the possibility exists. Less than a dozen cases have been published; most of them are not substantiated, and the few that may be accepted are not rigidly unequivocal (Jubb, 1943). As to the present case, the concurrence of encephalitis is not to be readily presumed, for though encephalitis is not a characteristic of generalized vaccinia the sensitivity of the infant central nervous system to febrile and toxic states is well known, and that could have been the explanation here. So, while encephalitis may not be entirely excluded, we prefer to regard the case as one of generalized vaccinia in which the toxæmia disappeared quickly after the administration of a serum containing specific antibody. That the serum favourably influenced the rash and accelerated its decline is suggested, but the condition of sepsis no doubt prevented any striking confirmation of this effect.

### Control of Crab Lice

Crab lice (*Phthirus pubis*) present a troublesome though minor problem, and most of the usual methods for dealing with them are inefficient and also necessitate shaving, with subsequent discomfort to the patient. Organic thiocyanates have been shown to be very effective against head and body lice (Busvine and Buxton, *B.M.J.*, 1942, 1, 464). These chemicals are also lethal to crab lice. Two substances—lanette 384 special and technical lauryl thiocyanate—have been used against head lice. The first of these is rather irritant to the human skin and causes great discomfort when applied to the genitals, so it is not suitable for treating crab lice. An emulsion of technical lauryl thiocyanate caused little discomfort and was very effective. The emulsion was made up as follows:

Lauryl thiocyanate ..	50 mls
Lanette wax S.X. ..	20 g.
Water ..	950 mls

The lanette wax was melted on a water bath, the lauryl thiocyanate added, and the mixture heated to a temperature of between 60° and 70° C. The mixture was poured into the water, previously heated to the same temperature, and stirred until cold.

In all, 177 patients suffering from crab lice were treated with the emulsion, which was applied to the affected areas; the hair was never shaved. One application only was given, and this took under 10 c.cm. of the emulsion. The clothing and bedding of each patient were disinfested. No single relapse occurred in the 177 cases so treated. It should be remembered that crab lice may be found on hair on any part of the body and not only in the pubic region.

"Technical lauryl thiocyanate" is a commercial product, and not a pure substance; all batches may possibly not be equally effective insecticides.

Sorby Research Institute, Sheffield.

KENNETH MELLANBY, Sc.D.

## Reviews

### PSEUDO-SCIENCE AND THE ART OF MEDICINE

*Nervousness, Indigestion, and Pain* By Walter C. Alvarez, M.D.  
(Pp. 488, 25s.) London: William Heinemann

It is to be hoped that this timely book will carry the more weight because the author of *An Introduction to Gastroenterology* cannot be suspected of indifference to the claims of the laboratory. In the present volume, entitled *Nervousness, Indigestion, and Pain*, Prof. Alvarez castigates a pernicious tendency in modern medicine to rely unduly on laboratory tests to the neglect of clinical investigation. We may justly hope that this abuse does not flourish here to the extent he indicates it prevails in the United States, but if we say we are without sin in that respect we deceive ourselves. What could be worse than such an occurrence as this: "Much-travelled patients have told me of their experiences with one busy consultant after another who did not say ten words to them until every conceivable test had been made by laboratory workers, roentgenologists, and specialists. Then the doctor glanced over the pile of reports, commented on the positive findings, promised to mail a copy of the record, gave a prescription or two, and led the way to the door." This is solemn pseudo-scientific quackery. Many of such tests were carried out by "laboratory girls," who, we gather, are not fully trained. What leads to such a state of affairs? Partly it is the outcome of a machine-minded age. As the late Dr. Crookshank sarcastically remarked, "What the patient says is not evidence, what a lever traces on a smoked drum is evidence." Partly it is done to impress the patient and largely to shelve responsibility; also there can be little doubt that it is often in answer to the patient's demands. Particularly this is likely to be the case with a psychoneurotic who dreads the verdict of "just nerves" so much that he or she is insistent on a physical cause being found. But this does not excuse the omission to make a routine clinical examination. In one case described all sorts of tests were done, but not a blood count; nor was the abdomen palpated till the patient went to a good general practitioner, who at once felt a large spleen, looked at a blood film, and in a minute diagnosed leukaemia. Another vicious plan is to carry out all the tests when at the outset the cause had been found, such as a carcinoma of the stomach or rectum.

One feels that there must be something fundamentally wrong with an education which can permit this state of things. Prof. J. A. Ryle has indicated one important factor. When a new patient is admitted the chief assistant and house-physician try to collect all the evidence they can before the arrival of the visiting physician. It is important that the chief should first go over the case from a purely clinical standpoint, and push the diagnosis as far as he can before he allows the laboratory reports to be looked at. Actions speak louder than words, as we know, and when the student observes the order in which his superiors proceed he naturally puts the emphasis in the wrong place. What they seem to think important must be so to him. The result of such methods is familiar to most examiners. Recently out of 50 candidates asked the simplest way to distinguish between obstructive and non-obstructive jaundice only three said they would look at the stools; all the others said they would have a Van den Bergh test done. A test of doubtful validity as opposed to a simple conclusive observation. Candidates often refuse to diagnose a straightforward case of aortic regurgitation without a Wassermann reaction, and will ask for an electrocardiogram without feeling the pulse. When directed to do so it seems to convey no information to them. One could multiply examples. At the present time expense is often a deterrent to the performance of tests that are not really necessary, and we may well speculate on what may happen if that expense is charged to the taxpayer.

This is not scientific medicine, and the art of medicine is not, as some correspondents to our columns have contemptuously maintained, merely a good bedside manner. It is an acquired skill in assessing the whole personality and outlook of the patient. And the book before us is full of good advice on that aspect, some of which might seem rather elementary and naive if the earlier sections had not shown

how urgent is the need for it. The prime importance of taking a full history is emphasized repeatedly; most physicians find that with increasing experience they devote a larger part of their time with their patients to this, and they can carry out an adequate examination in a shorter time. The author calls attention to one melancholy result of failure to elicit all the factors in the history: the light-hearted way in which his surgical colleagues open the abdomen repeatedly for vague pains without proper inquiry into psychological factors.

It is sometimes complained that students are not sufficiently informed as to the proper approach to a sick person and the management of the environmental conditions. This book will give them much practical help on such points. But it is salutary reading for all practitioners as showing that pseudo-science can harm medicine as much as any of the superstitions of the past. Each chapter is headed by several pertinent quotations. We will present the author with a motto which would serve for the whole book—"In clinical medicine the laboratory is a good servant but a bad master."

W. L. B.

### OPERATIVE SURGERY

*Modern Operative Surgery*, Edited by G. Grey Turner, Vol. 11 (In two volumes) Third edition. (Pp. 2,236, illustrated 55s.) London: Cassell and Co.

It is now nearly ten years since the second edition of *Modern Operative Surgery* was published, and twenty years since the first edition appeared under the editorship of H. W. Carson. During that time it has established itself as an authoritative work, which is recognized as being truly representative of sane British surgery. While the second edition was in preparation the original editor died and the work was completed by Prof. Grey Turner. He continues as editor of the third edition, the second volume of which is now under review. For the most part the authors of the various sections are unchanged, but neurosurgery is now in the hands of Prof. Jefferson, Mr. Ogier Ward writes on the bladder and prostate, Mr. Negus on the upper respiratory passages, Mr. Gardham on the mouth and tongue, while the gynaecological section is by Mr. Rivett.

In general the book may be described as well balanced both in matter and in outlook. The authors have carefully avoided the temptation to make it a mere catalogue of all possible operations and have devoted their space to a detailed account of the workaday operations of general surgical practice. This is all to the good, for it makes the volume extremely valuable to the more junior surgeons who have scarcely enough experience as yet to justify individual opinions or methods, and to older surgeons who may find themselves called upon to perform operations a little outside their usual sphere. The opinions expressed are quite sound; whether it be in the choice of procedures or in estimating prognosis, there is little in the advice given at which any broadminded surgeon would cavil. The general standard of the information in all sections is so high that it would be invidious to pick on one for special mention, yet the reviewer was particularly impressed by the quality of the entirely new chapter on neurosurgery. Here the general surgeon will find an excellent epitome of the modern surgery of the brain, in which all the salient points are adequately described. It is a chapter displaying that breadth of view which one associates with authors who have a wide general experience in addition to their specialized knowledge of a particular subject.

The illustrations throughout the book are numerous and of high quality; the production is much better than would be expected in these days of quantitative and qualitative paper restrictions.

### UNIT MEDICAL RECORDS

*Unit Medical Records in Hospital and Clinic*, By Dorothy L. Kurtz, (Pp. 110, 52.00 or 13s. 6d.) New York: Columbia University Press; London: Oxford University Press

There are three parts to any efficient system of medical record keeping. The first is the actual writing of the notes. The second is the affixing of a diagnosis and the preparation of indexes of names and diagnoses. The third is the presentation of the individual record in a convenient and accessible form. It is with the third of these things that this book deals. Medical records will become increasingly important in this country with the development of health centres and the establishment of a national consultant service. Miss Kurtz outlines

a system in which the notes on all the admissions of a patient to a hospital are bound together, and all these notes—in-patient, out-patient, and follow-up—are arranged in chronological order. This seems easy in theory, but in practice it is extremely difficult if the note is to be continuously and easily accessible. It will rarely be possible to duplicate exactly the system followed at the Presbyterian Hospital, from which this book comes, for much depends on the physical structure and layout of the clinic or hospital. But a very great deal can be learned from their 25 years' experience.

We have long recognized the need for instruction in the making of medical case histories both as a training in accurate observation and as a means of recording what has happened to the patient. We have been slower to learn that much of the value of this material is wasted if it is not accurately indexed and filed. A detailed note of a single patient's admission to a hospital may cost at least £1 if the cost of paper, typing, records clerks, overhead charges on equipment, etc., is fairly assessed. Many people, lay people especially, wonder whether his money is well spent. Its first value is to the patient, particularly if he comes again under medical treatment and reference must be made to his previous illness. We have also mentioned the value of the note as a professional discipline, whether the writer is a student or a qualified practitioner. The third use of the note is as the source material for morbid statistics. Finally, it may have value for clinical research, though we agree with Miss Kurtz that material for clinical research is more likely to be obtained from current than from past records. Research, in fact, depends on planned seeking. For all these reasons accurate detailed notes and practicable filing systems are essential. The Americans have found it desirable to create an association of medical record librarians to advance and standardize the quality of medical records, and some such ancillary profession seems a necessary corollary to the co-ordination and up-grading of hospital treatment which are taking place in this country. Record keeping, like business management, is something that has to be learned, and Miss Kurtz has written an indispensable textbook.

### Notes on Books
